EPA Response: In response to comments, the EPA compared the projected 2023 design values based on the proposal modeling to recent trends in measured data. As a result of this analysis, the EPA agrees that current data indicate that there are monitoring sites at risk of continued nonattainment in 2023 even though the model projected average and maximum design values at these sites are below the NAAQS (*i.e.,* these sites would not be modeling-based receptors at Step 1). While the EPA has confidence in the reliability of the modeling for projecting air quality conditions and contributions in future years, it would not be reasonable to ignore recent measured ozone levels in many areas that are clearly not fully consistent with certain concentrations in the Step 1 analysis for 2023. Therefore, the EPA has developed an additional maintenance-only receptor category, which includes what we refer to as ''violating monitor'' receptors, based on current ozone concentrations measured by regulatory ambient air quality monitoring sites.

Specifically, the EPA has identified monitoring sites with measured 2021 and preliminary 2022 design values *and* 4th high maximum daily 8-hour average (MDA8) ozone in both 2021 and 2022 (preliminary data) that exceed the NAAQS as having the greatest risk of continuing to have a problem attaining the standard in 2023. These criteria sufficiently consider measured air quality data so as to avoid including monitoring sites that have measured nonattainment data in recent years but could reasonably be anticipated to not have a nonattainment or maintenance problem in 2023, in line with our modeling results. Our methodology is intended only to identify those sites that have sufficiently poor ozone levels that there is clearly a reasonable expectation that an ozone nonattainment or maintenance problem will persist in the 2023 ozone season. Moreover, the 2023 ozone season is so near in time that recent measured ozone levels can be used to reasonably project whether an air quality problem is likely to persist. We view this approach to identifying additional receptors in 2023 as the best means of responding to the comments on this issue in this action, while also identifying all transport receptors.

For purposes of this action, we will treat these violating monitors as an additional type of maintenance-only receptor. We acknowledge that the traditional modeling plus monitoring methodology we used at proposal and in prior ozone transport rules would otherwise have identified such sites as being in attainment in 2023. Because our modeling did not identify these sites as receptors, we do not believe it is sufficiently certain that these sites will be in nonattainment that they should be considered nonattainment receptors. In the face of this uncertainty in the record, we regard our ability to consider such sites as receptors for purposes of good neighbor analysis under CAA section 110(a)(2)(D)(i)(I) to be a function of the requirement to prohibit emissions that interfere with maintenance of the NAAQS; even if an area may be projected to be in attainment, we have reliable information indicating that there is a clear risk that attainment will not in fact be achieved in 2023. Thus, our authority for treating these sites as receptors at Step 1 in 2023 flows from the responsibility in CAA section 110(a)(2)(i)(I) to prohibit emissions that interfere with maintenance of the NAAQS. *See, e.g., North Carolina,* 531 F.3d at 910–11 (failing to give effect to the interfere with maintenance clause ''provides no protection for downwind areas that, *despite EPA's predictions,* still find themselves struggling to meet NAAQS due to upwind interference . . . .'') (emphasis added). Recognizing that no modeling can perfectly forecast the future, and ''a degree of imprecision is inevitable in tackling the problem of interstate air pollution,'' this approach in the Agency's judgement best balances the need to avoid both ''under-control'' and ''overcontrol,'' *EME Homer City,* 572 U.S. at 523. The EPA's analysis of these additional receptors further is explained in Section III.C.

However, because we did not propose to apply this expansion of the basis for regulation under the good neighbor provision receptor-identification methodology as the sole basis for finding an upwind state linked, in this action we are only using this receptor category on a confirmatory basis. That is, for states that we find linked based on our traditional modeling-based methodology in 2023, we find in this final analysis that the linkage at Step 2 is strengthened and confirmed if that state is also linked to one or more ''violating-monitor'' receptors. If a state is only linked to a violating-monitor receptor in this final analysis, we are deferring taking final action on that state's SIP submittal. This is the case for the State of Tennessee. Among the states that previously had their transport SIPs approved for the 2015 ozone NAAQS, the EPA has also identified a linkage to violating-monitor receptors for the State of Kansas. The EPA intends to further review its air quality modeling results and recent measured ozone levels, and we intend to address these states' good

[76] *EME Homer City II,* 795 F.3d at 136.

[77] *See https://www.epa.gov/air-trends/air-quality-design-values* for design value reports. At the time of this action, the most recent reports of certified design values available are for the calendar year 2021. The 2022 values are considered ''preliminary'' and therefore subject to change before certification.

neighbor obligations as expeditiously as practicable in a future action.

2. Methodology for Projecting Future Year Ozone Design Values

Consistent with the EPA's modeling guidance, the 2016 base year and future year air quality modeling results were used in a relative sense to project design values for 2023.[78] That is, the ratios of future year model predictions to base year model predictions are used to adjust ambient ozone design values up or down depending on the relative (percent) change in model predictions for each location. The EPA's modeling guidance recommends using measured ozone concentrations for the 5-year period centered on the base year as the air quality data starting point for future year projections. This average design value is used to dampen the effects of inter-annual variability in meteorology on ozone concentrations and to provide a reasonable projection of future air quality at the receptor under average conditions. In addition, the Agency calculated maximum design values from within the 5-year base period to represent conditions when meteorology is more favorable than average for ozone formation. Because the base year for the air quality modeling used in this final action is 2016, measured data for 2014–2018 (*i.e.,* design values for 2016, 2017, and 2018) were used to project average and maximum design values in 2023.

The ozone predictions from the 2016 and future year air quality model simulations were used to project 2016–2018 average and maximum ozone design values to 2023 using an approach similar to the approach in the EPA's guidance for attainment demonstration modeling. This guidance recommends using model predictions from the 3 x 3 array of grid cells surrounding the location of the monitoring site to calculate a Relative Response Factor (RRF) for that site. However, the guidance also notes that an alternative array of grid cells may be used in certain situations where local topographic or geographical feature (*e.g.,* a large water body or a significant elevation change) may influence model response.

The 2016–2018 base period average and maximum design values were multiplied by the RRF to project each of these design values to 2023. In this manner, the projected design values are grounded in monitored data, and not the absolute model-predicted future year concentrations. Following the approach in the CSAPR Update and the Revised CSAPR Update, the EPA also projected future year design values based on a modified version of the ''3 x 3'' approach for those monitoring sites located in coastal areas. In this alternative approach, the EPA eliminated from the RRF calculations the modeling data in those grid cells that are dominated by water (*i.e.,* more than 50 percent of the area in the grid cell is water) and that do not contain a monitoring site (*i.e.,* if a grid cell is more than 50 percent water but contains an air quality monitor, that cell would remain in the calculation). The choice of more than 50 percent of the grid cell area as water as the criteria for identifying overwater grid cells is based on the treatment of land use in the Weather Research and Forecasting model (WRF). Specifically, in the WRF meteorological model those grid cells that are greater than 50% overwater are treated as being 100 percent overwater. In such cases the meteorological conditions in the entire grid cell reflect the vertical mixing and winds over water, even if part of the grid cell also happens to be over land with land-based emissions, as can often be the case for coastal areas. Overlaying land-based emissions with overwater meteorology may be representative of conditions at coastal monitors during times of on-shore flow associated with synoptic conditions or sea-breeze or lake-breeze wind flows. But there may be other times, particularly with off-shore wind flow, when vertical mixing of land-based emissions may be too limited due to the presence of overwater meteorology. Thus, for our modeling the EPA projected average and maximum design values at individual monitoring sites based on both the ''3 x 3'' approach as well as the alternative approach that eliminates overwater cells in the RRF calculation for near-coastal areas (*i.e.,* ''no water'' approach). The projected 2023 design values using both the ''3 x 3'' and ''no-water'' approaches are provided in the docket for this final action. Both approaches result in the same set of receptors in 2023. That is, monitoring sites that are identified as receptors in 2023 based on the ''3 x 3'' approach are also receptors based on the ''no water'' approach.

Consistent with the truncation and rounding procedures for the 8-hour ozone NAAQS, the projected design values are evaluated after truncation to integers in units of ppb. Therefore, projected design values that are greater than or equal to 71 ppb are considered to be violating the 2015 ozone NAAQS. For those sites that are projected to be violating the NAAQS based on the average design values in 2023, the Agency examined the measured design values for 2021, which are the most recent official measured design values at the time of this final action.

As noted earlier, the Agency proposes to identify nonattainment receptors in this rulemaking as those sites that are violating the NAAQS based on current measured air quality through 2021 and have projected average design values of 71 ppb or greater. Maintenance-only receptors include both: (1) Those sites with projected average design values above the NAAQS that are currently measuring clean data (*i.e.,* ozone design values below the level of the 2015 ozone NAAQS in 2021) and (2) those sites with projected average design values below the level of the NAAQS, but with projected maximum design values of 71 ppb or greater. In addition to the maintenance-only receptors, ozone nonattainment receptors are also maintenance receptors because the projected maximum design values for each of these sites is always greater than or equal to the average design value. Further, as explained previously in this section, the EPA identifies certain monitoring sites as ''violating monitor'' maintenance-only receptors based on 2021 and 2022 measured ozone levels.

The monitoring sites that the Agency projects to be nonattainment and maintenance receptors for the ozone NAAQS in the 2023 base case are used for assessing the contribution of emissions in upwind states to downwind nonattainment and maintenance of the 2015 ozone NAAQS as part of this final action.

3. 2023 Nonattainment and Maintenance-Only Receptors for the Final Action

In this section we provide information on modeling-based design values and measured data for monitoring sites identified as nonattainment or maintenance-only receptors in 2023 for this final action. Table III.B–1 of this action contains the 2016-centered base period average and maximum 8-hour ozone design values, the 2023 projected average and maximum design values and the measured 2021 design values for monitoring sites that are projected to be nonattainment receptors in 2023. Table III.B–2 of this action contains this same information for monitoring sites that are projected to be maintenance-only receptors in 2023, based on air quality modeling. Table III.B–3 of this action contains the 2023 projected average and maximum design values and 2021 design values and 4th high

[78] U.S. Environmental Protection Agency, 2018. Modeling Guidance for Demonstrating Attainment of Air Quality Goals for Ozone, $PM_{2.5}$, and Regional Haze, Research Triangle Park, NC. *https://www.epa.gov/scram/state-implementation-plan-sip-attainment-demonstration-guidance.*

MDA8 ozone concentrations and preliminary 2020 design values and 4th high MDA8 ozone concentrations for monitoring sites identified as violating monitor maintenance-only receptors. The design values for all monitoring sites in the U.S. are provided in the docket for this action. Additional details on the approach for projecting average and maximum design values are provided in the AQM TSD.

551010020	WI	Racine	76.0	78	69.7	71.5	73

In total, in 2023 there are a total of projected 33 modeling-based receptors nationwide including 14 nonattainment receptors in 9 different counties and 19 maintenance-only receptors in 13 additional counties (Harris County, TX, has both nonattainment and maintenance-only receptors).

As shown in Table III.B–3 of this action, there are 49 monitoring sites that are identified as ''violating-monitor'' maintenance-only receptors in 2023.As noted earlier in this section, the EPA uses the approach of considering ''violating-monitor'' maintenance-only receptors as confirmatory of the proposal's identification of receptors and does not implicate additional linked states in this final action, Rather, using this approach serves to strengthen the analytical basis for our Step 2 findings by establishing that many upwind states covered in this action are also projected to contribute above 1 percent of the NAAQS to these additional ''violating monitor'' maintenance-only receptors.

[a] 2022 preliminary design values are based on 2022 measured MDA8 concentrations provided by state air agencies to the EPA's Air Quality System (AQS), as of January 3, 2023.

C. Air Quality Modeling To Quantify Upwind State Contributions

This section documents the procedures the EPA used to quantify the impact of emissions from specific upwind states on ozone design values in 2023 for the identified downwind nonattainment and maintenance receptors. The EPA used CAMx photochemical source apportionment modeling to quantify the impact of emissions in specific upwind states on downwind nonattainment and maintenance receptors for 8-hour ozone. CAMx employs enhanced source apportionment techniques that track the formation and transport of ozone from specific emissions sources and calculates the contribution of sources and precursors to ozone for individual receptor locations. The benefit of the photochemical model source apportionment technique is that all modeled ozone at a given receptor location in the modeling domain is tracked back to specific sources of emissions and boundary conditions to fully characterize culpable sources.

The EPA performed nationwide, state-level ozone source apportionment modeling using the CAMx Ozone Source Apportionment Technology/Anthropogenic Precursor Culpability Analysis (OSAT/APCA) technique [79] to quantify the contribution of 2023 NO_X and VOC emissions from all sources in each state to the corresponding projected ozone design values in 2023 at

[79] As part of this technique, ozone formed from reactions between biogenic VOC and NO_X with anthropogenic NO_X and VOC are assigned to the anthropogenic emissions.

air quality monitoring sites. The CAMx OSAT/APCA model run was performed for the period May 1 through September 30 using the projected future base case emissions and 2016 meteorology for this time period. In the source apportionment modeling the Agency tracked (*i.e.,* tagged) the amount of ozone formed from anthropogenic emissions in each state individually as well as the contributions from other sources (*e.g.,* natural emissions).

In the state-by-state source apportionment model run, the EPA tracked the ozone formed from each of the following tags:

• States—anthropogenic NO_X emissions and VOC emissions from individual state (emissions from all anthropogenic sectors in a given state were combined);

• Biogenics—biogenic NO_X and VOC emissions domain-wide (*i.e.,* not by state);

• Boundary Concentrations—concentrations transported into the air quality modeling domain;

• Tribes—the emissions from those tribal lands for which the Agency has point source inventory data emissions modeling platform (EPA did not model the contributions from individual tribes);

• Canada and Mexico—anthropogenic emissions from those sources in the portions of Canada and Mexico included within the modeling domain (the EPA did not model the contributions from Canada and Mexico separately);

• Fires—combined emissions from wild and prescribed fires domain-wide (*i.e.,* not by state); and

• Offshore—combined emissions from offshore marine vessels and offshore drilling platforms within the modeling domain.

The contribution modeling provided contributions to ozone from anthropogenic NO_X and VOC emissions in each state, individually. The contributions to ozone from chemical reactions between biogenic NO_X and VOC emissions were modeled and assigned to the ''biogenic'' category. The contributions from wildfire and prescribed fire NO_X and VOC emissions were modeled and assigned to the ''fires'' category. That is, the contributions from the ''biogenic'' and ''fires'' categories are not assigned to individual states nor are they included in the state contributions.

For the Step 2 analysis, the EPA calculated a contribution metric that considers the average contribution on the 10 highest ozone concentration days (*i.e.,* top 10 days) in 2023 using the same approach as the EPA used in the proposed action and in the Revised CSAPR Update.[80] This average contribution metric is intended to provide a reasonable representation of the contribution from individual states to projected future year design values, based on modeled transport patterns and other meteorological conditions generally associated with modeled high ozone concentrations at the receptor. An average contribution metric constructed in this manner ensures the magnitude of the contributions is directly related to the magnitude of the ozone design value at each site.

The analytic steps for calculating the contribution metric for the 2023 analytic year are as follows:

(1) Calculate the 8-hour average contribution from each source tag to individual ozone monitoring site for the time period of the 8-hour daily maximum modeled concentrations in 2023;

(2) Average the contributions and average the concentrations for the top 10 modeled ozone concentration days in 2023;

(3) Divide the average contribution by the corresponding average concentration to obtain a Relative Contribution Factor (RCF) for each monitoring site;

(4) Multiply the 2023 average design value by the 2023 RCF at each site to produce the average contribution metric values in 2023;[81]

(5) Truncate the average contribution metric values to two digits to the right of the decimal for comparison to the 1 percent of the NAAQS screening threshold (0.70 ppb)

The resulting contributions from each tag to each monitoring site in the U.S. for 2023 can be found in the docket for this final action. Additional details on the source apportionment modeling and the procedures for calculating contributions can be found in the AQM TSD. The EPA's response to comments on the method for calculating the contribution metric can be found in the RTC document for this final action.

The largest contribution from each state that is the subject of this final action to modeled 8-hour ozone nonattainment and modeling-based maintenance receptors in downwind states in 2023 are provided in Table III.C–1 of this action. The largest contribution from each state to the additional ''violating monitor'' maintenance-only receptors is provided in Table III.C–2 of this action. All states that are linked to one or more nonattainment or maintenance-only receptors are also linked to one or more violating monitor maintenance receptors, except for Minnesota.

TABLE III.C–1—LARGEST CONTRIBUTION BY STATE TO DOWNWIND 8-HOUR OZONE NONATTAINMENT AND MAINTENANCE RECEPTORS IN 2023 (ppb)

Upwind state	Largest contribution to a downwind nonattainment receptor	Largest contribution to a downwind maintenance-only receptor
Alabama	0.75	0.65
Arkansas	0.94	1.21
California	35.27	6.31
Illinois	13.89	19.09
Indiana	8.90	10.03
Kentucky	0.84	0.79
Louisiana	9.51	5.62

[80] The use of daily contributions on the top 10 concentration days for calculating the average contribution metric is designed to be consistent with the method specified in the modeling guidance in terms of the number of days to use when projecting future year design values.

[81] Note that a contribution metric value was not calculated for any receptor at which there were fewer than 5 days with model-predicted MDA8 ozone concentrations greater than or equal to 60 ppb in 2023. Eliminating from the Step 2 evaluation any receptors for which the modeling does not meet this criterion ensures that upwind state contributions are based on the days with the highest ozone projections. This criterion is consistent with the criterion for projecting design values, as recommended in the EPA's modeling guidance. In the modeling for this final action, the monitoring site in Seattle, Washington (530330023), was the only receptor that did not meet this criterion.

TABLE III.C–1—LARGEST CONTRIBUTION BY STATE TO DOWNWIND 8-HOUR OZONE NONATTAINMENT AND MAINTENANCE RECEPTORS IN 2023 (ppb)—Continued

Upwind state	Largest contribution to a downwind nonattainment receptor	Largest contribution to a downwind maintenance-only receptor
Maryland	1.13	1.28
Michigan	1.59	1.56
Minnesota	0.36	0.85
Mississippi	1.32	0.91
Missouri	1.87	1.39
Nevada	1.11	1.13
New Jersey	8.38	5.79
New York	16.10	11.29
Ohio	2.05	1.98
Oklahoma	0.79	1.01
Texas	1.03	4.74
Utah	1.29	0.98
West Virginia	1.37	1.49
Wisconsin	0.21	2.86

TABLE III.C–2—LARGEST CONTRIBUTION TO DOWNWIND 8-HOUR OZONE "VIOLATING MONITOR" MAINTENANCE-ONLY RECEPTORS (ppb)

Upwind State	Largest contribution to a downwind violating monitor maintenance-only receptor
Alabama	0.79
Arkansas	1.16
California	6.97
Illinois	16.53
Indiana	9.39
Kentucky	1.57
Louisiana	5.06
Maryland	1.14
Michigan	3.47
Minnesota	0.64
Mississippi	1.02

Nevada	1.11
New Jersey	8.00
New York	12.08
Ohio	2.25
Oklahoma	1.57
Texas	3.83
Utah	1.46
West Virginia	1.79
Wisconsin	5.10

IV. Summary of Bases for Disapproval

As explained in Section II, the EPA relies on the 4-step interstate transport framework to evaluate obligations under CAA section 110(a)(2)(D)(i)(I). At proposal, the EPA used this framework to guide its evaluation of each state's SIP submission. While the EPA used this framework to maintain a nationally consistent and equitable approach to interstate transport, the contents of each individual state's submission were evaluated on their own merits, and the EPA considered the facts and information, including information from the Agency, available to the state at the time of its submission, in addition to more recent air quality and contribution information. Here we provide a brief, high level overview of the SIP submissions and the EPA's evaluation and key bases for disapproval. These summaries are presented for ease of reference and to direct the public to the most relevant portions of the proposals and final rule record for further information. The full basis for the EPA's disapprovals is available in relevant **Federal Register** notifications of proposed disapproval for each state, in the technical support documents informing the proposed and final action, and in the responses to comments in Section V and the RTC document. In general, except as otherwise noted, the comments and updated air quality information did not convince the Agency that a change from proposal was warranted for any state. The exceptions are that the EPA is deferring action at this time on the proposed disapprovals for Tennessee and Wyoming. Further, the EPA is finalizing partial approvals of prong 1 (''significant contribution to nonattainment'') for Minnesota and Wisconsin because they are linked only to maintenance-only receptors; the EPA is finalizing a partial disapproval with respect to prong 2 (''interference with maintenance'') obligations for these two states.

A. Alabama

In the 2016v3 modeling, Alabama is projected to be linked above 1 percent of the NAAQS to one nonattainment receptor. It is also linked to one violating-monitor maintenance-only receptor. Its highest-level contribution is 0.75 ppb to Galveston County, Texas (AQS Site ID 481671034).[82] A full summary of Alabama's June 21, 2022, SIP submission, as well as Alabama's previous submission history, was provided in the proposed SIP submission disapproval.[83] In its submission, Alabama advocated for discounting maintenance receptors through use of historical data trends. The EPA finds Alabama's approach is not adequately justified.[84] The EPA disagrees with Alabama's assessment of the 2016v2 modeling,[85] and further responds to comments on model performance in Section III. The EPA disagrees with Alabama's arguments for application of a higher contribution threshold than 1 percent of the NAAQS at Step 2,[86] and further addresses the relevance of ''significant impact levels'' within the Prevention of Significant Deterioration program (''PSD SILs'') in Section V.B.6. The EPA found technical flaws in Alabama's back trajectory analysis.[87] The State did not conduct an adequate Step 3 analysis, and the EPA identified several unsupported assertions in the SIP submission.[88] Alabama also argued in its SIP submission that it had already implemented all cost-effective controls. However, the State included an insufficient evaluation of additional emissions control opportunities to support such a conclusion.[89] The EPA further addresses arguments related to

[82] The highest-magnitude downwind contribution from each state is based on the contributions to modeling-based receptors and does not consider the contributions to violating-monitor maintenance-only receptors. Each state's maximum contribution to downwind violating-monitor maintenance-only receptors is available in the Final Action AQM TSD.

[83] 87 FR 64419–64421.

[88] Id. at 64425–64426.

[89] Id.

mobile sources in Section V.C.1.[90] Additionally, as explained in Section V.B.9,[91] reliance on prior transport FIPs such as the CSAPR Update is not a sufficient analysis at Step 3. The State included no permanent and enforceable emissions controls in its SIP submission.[92] We provide further response to comments regarding Alabama's SIP submission in the RTC document. The EPA is finalizing disapproval of Alabama's interstate transport SIP submission for the 2015 ozone NAAQS.

B. Arkansas

In the 2016v3 modeling, Arkansas is projected to be linked above 1 percent of the NAAQS to one nonattainment receptor and five maintenance-only receptors. It is also linked to seven violating-monitor maintenance-only receptor. Its highest-level contribution is 1.21 ppb to Brazoria County Texas (AQS Site ID 480391004). A full summary of Arkansas's October 10, 2019, SIP submission was provided in the proposed SIP submission disapproval.[93] The EPA disagrees with Arkansas's arguments for application of a higher contribution threshold than 1 percent of the NAAQS at Step 2, and further addresses the relevance of PSD SILs in Section V.B.6.[94] The EPA also found technical flaws in Arkansas's ''consistent and persistent'' claims and back trajectory analysis,[95] and legal flaws in the state's arguments related to relative contribution.[96] The State did not conduct an adequate Step 3 analysis.[97] Arkansas argued in its SIP submission that it had already implemented all cost-effective controls. However, the State included an insufficient evaluation of additional emissions control opportunities to support such a conclusion.[98] Further, the State's reliance on the cost-effectiveness thresholds in the CSAPR and CSAPR Update is insufficient for the more protective 2015 ozone NAAQS.[99] The State included no permanent and enforceable controls in its SIP submission.[100] We provide further response to comments regarding Arkansas's SIP submission in the RTC document. The EPA is finalizing disapproval of Arkansas's interstate transport SIP submission for the 2015 ozone NAAQS.

C. California

In the 2016v3 modeling, California is projected to be linked above 1 percent of the NAAQS to eight nonattainment receptors and four maintenance-only receptors. It is also linked to 26 violating-monitor maintenance-only receptor. Its highest-level contribution is 35.27 ppb to the nonattainment receptor located on the Morongo Band of Missions Indians reservation (AQS Site ID 060651016).[101] A full summary of California's October 1, 2018, SIP submission was provided in the proposed SIP submission disapproval.[102] The EPA found technical and legal flaws in California's geographic, meteorological, wildfire, and trajectories analysis, and the State's arguments related to local, international, and non-anthropogenic emissions.[103] The EPA further addresses the topic of international emissions in Section V.C.2. The State did not conduct an adequate Step 3 analysis.[104] California in its SIP submission argued that it had already implemented all cost-effective controls. However, California provided an insufficient evaluation of additional control opportunities to support such a conclusion.[105] Further, the State's reliance on the cost-effectiveness threshold in the CSAPR Update is insufficient for the more protective 2015 ozone NAAQS.[106] California included no permanent and enforceable emissions controls in its SIP submission [107] and argued that interstate transport is fundamentally different in the western U.S. than in the eastern U.S., to which the EPA responds in Section V.C.3.[108] We provide further response to comments regarding California's SIP submission in the RTC document. The EPA is finalizing disapproval of California's interstate transport SIP submission for the 2015 ozone NAAQS.

D. Illinois

In the 2016v3 modeling, Illinois is projected to be linked above 1 percent of the NAAQS to two nonattainment receptors and three maintenance-only receptors. It is also linked to six violating-monitor maintenance-only receptor. Its highest-level contribution is 19.09 ppb to Kenosha County, Wisconsin (AQS Site ID 550590019). A full summary of Illinois's May 21, 2019, SIP submission was provided in the proposed SIP submission disapproval.[109] The EPA disagrees with Illinois's arguments for application of a higher contribution threshold than 1 percent of the NAAQS at Step 2.[110] The state did not conduct an adequate Step 3 analysis.[111] The State included an insufficient evaluation of additional emissions control opportunities in its SIP submission.[112] The EPA also found technical and legal flaws in Illinois' arguments related to ''on-the-way'' controls, participation in the Lake Michigan Air Directors Consortium (LADCO), and international contributions.[113] The EPA further addresses the topic of international contribution in Section V.C.2. Further, as explained in Section V.B.9., states may not rely on non-SIP measures to meet SIP requirements, and reliance on prior transport FIPs such as the CSAPR Update is not a sufficient analysis at Step 3.[114] The State included no permanent and enforceable controls in its SIP submission.[115] We provide further response to comments regarding Illinois's SIP submission in the RTC document. The EPA is finalizing disapproval of Illinois's interstate

[101] We note that, consistent with the EPA's prior good neighbor actions in California, the regulatory ozone monitor located on the Morongo Band of Mission Indians (''Morongo'') reservation is a projected downwind receptor in 2023. *See* monitoring site 060651016 in Table V.D–1. of this action. We also note that the Temecula, California, regulatory ozone monitor is a projected downwind receptor in 2023 and in past regulatory actions has been deemed representative of air quality on the Pechanga Band of Luiseño Indians (''Pechanga'') reservation. *See, e.g.,* Approval of Tribal Implementation Plan and Designation of Air Quality Planning Area; Pechanga Band of Luiseño Mission Indians, 80 FR 18120, at 18121–18123 (April 3, 2015); *see* also monitoring site 060650016 in Table V.D–1. of this action. The presence of receptors on, or representative of, the Morongo and Pechanga reservations does not trigger obligations for the Morongo and Pechanga Tribes. Nevertheless, these receptors are relevant to the EPA's assessment of any linked upwind states' good neighbor obligations. *See, e.g.,* Approval and Promulgation of Air Quality State Implementation Plans; California; Interstate Transport Requirements for Ozone, Fine Particulate Matter, and Sulfur Dioxide, 83 FR 65093 (December 19, 2018). Under 40 CFR 49.4(a), tribes are not subject to the specific plan submittal and implementation deadlines for NAAQS-related requirements, including deadlines for submittal of plans addressing transport impacts. We also note that California's maximum contribution to a downwind state receptor is 6.31 ppb in Yuma County, Arizona (AQS Site ID 040278011).

transport SIP submission for the 2015 ozone NAAQS.

E. Indiana

In the 2016v3 modeling, Indiana is projected to be linked above 1 percent of the NAAQS to four nonattainment receptors and six maintenance-only receptors. It is also linked to 10 violating-monitor maintenance receptors. Its highest-level contribution is 10.03 ppb to Racine County, Wisconsin (AQS Site ID 551010020). A full summary of Indiana's November 2, 2018, SIP submission was provided in the proposed SIP submission disapproval.[116] The EPA disagrees with Indiana's arguments for application of a higher contribution threshold than 1 percent of the NAAQS at Step 2.[117] The State did not conduct an adequate Step 3 analysis.[118] The EPA found technical and legal flaws in Indiana's arguments related to ozone concentration and design value trends, the timing of expected source shutdowns, local emissions, international and offshore contributions, Indiana's portion of contribution, and Indiana's back trajectory analysis.[119] The EPA further addresses the topic of international emissions in Section V.C.2. Indiana argued that it would not be cost-effective to implement controls on non-EGUs. However, the State included an insufficient evaluation of additional emissions control opportunities, for any type of source, to support that conclusion.[120] The EPA also confirmed that EGU shutdowns identified by Indiana were included in the 2016v2 modeling,[121] and if they were valid and not included in the 2016v2 modeling, then they were incorporated into the 2016v3 modeling as explained in Section III and the 2016v3 Emissions Modeling TSD. Further, in Section V.B.9., states may not rely on non-SIP measures to meet SIP requirements.[122] The State included no permanent and enforceable emissions controls in its SIP submission.[123] We provide further response to comments regarding Indiana's SIP submission in the RTC document. The EPA is finalizing disapproval of Indiana's interstate transport SIP submission for the 2015 ozone NAAQS.

F. Kentucky

In the 2016v3 modeling, Kentucky is projected to be linked above 1 percent of the NAAQS to two nonattainment receptors and one maintenance-only receptor. It is also linked to four violating-monitor maintenance-only receptor. Its highest-level contribution based on the 2016v3 modeling is 0.84 ppb to Fairfield County, Connecticut (AQS Site ID 090019003). A full summary of Kentucky's January 11, 2019, SIP submission was provided in the proposed SIP submission disapproval.[124] Although the EPA's 2016v3 modeling indicated a highest-level contribution below 1 ppb, the EPA disagrees with Kentucky's arguments for application of a higher contribution threshold than 1 percent of the NAAQS at Step 2.[125] Further, Kentucky is linked above 1 ppb to a violating-monitor receptor. The EPA addresses the relevance of the PSD SILs in Section V.B.6. The Commonwealth did not conduct an adequate Step 3 analysis.[126] The EPA found technical and legal flaws in Kentucky's arguments related to the level and timing of upwind versus downwind-state responsibilities, NO_X emissions trends and other air quality information, and back-trajectory analyses.[127] The EPA also found technical and legal flaws in certain State-level comments submitted by Midwest Ozone Group and attached to Kentucky's submission, including arguments related to international emissions.[128] The EPA further addresses the topics of international emissions in Section V.C.2. Kentucky in its SIP submission also argued that it had already implemented all cost-effective controls. However, the Commonwealth included an insufficient evaluation of additional emissions control opportunities to support such a conclusion.[129] As explained in Section V.B.9., states may not rely on non-SIP measures to meet SIP requirements, and reliance on prior transport FIPs such as the CSAPR Update is not a sufficient analysis at Step 3.[130] The EPA also confirmed in the proposed SIP submission disapproval that EGU shutdowns identified by Kentucky were included in the 2016v2 modeling, and yet Kentucky was still linked in that modeling.[131] Kentucky in its SIP submission advocated for lower interstate ozone transport responsibility for states linked only to maintenance-only receptors. The EPA finds Kentucky's arguments in this regard inadequately supported.[132] The Commonwealth included no permanent and enforceable emissions controls in its SIP submission.[133] We provide further response to comments regarding Kentucky's SIP submission in the RTC document. The EPA is finalizing disapproval of Kentucky's interstate transport SIP submission for the 2015 ozone NAAQS.

[129] Id. at 9511–9512.

[130] See also id. at. 9512.

G. Louisiana

In the 2016v3 modeling, Louisiana is projected to be linked above 1 percent of the NAAQS to two nonattainment receptors and five maintenance-only receptors. It is also linked to 10 violating-monitor maintenance-only receptor. Its highest-level contribution is 9.51 ppb to Galveston County Texas (AQS Site ID 481671034). A full summary of Louisiana's November 13, 2019, SIP submission was provided in the proposed SIP submission disapproval.[134] The EPA disagrees with Louisiana's arguments for application of a higher contribution threshold than 1 percent of the NAAQS and disagrees with Louisiana's criticisms of a 1 percent of the NAAQS contribution threshold at Step 2.[135] The EPA further addresses technical comments on the 1 percent of the NAAQS contribution threshold in Section V.B.4. Louisiana did not conduct an adequate Step 3 analysis.[136] The State included an insufficient evaluation of additional emissions control opportunities in its SIP submission.[137] The EPA also found technical flaws in Louisiana's "consistent and persistent" claims, assessment of seasonal weather patterns, surface wind directions, and back trajectory analysis.[138] The State included no permanent and enforceable controls in its SIP submission.[139] We provide further response to comments regarding Louisiana's SIP submission in the RTC document. The EPA is finalizing disapproval of Louisiana's interstate transport SIP submission for the 2015 ozone NAAQS.

[138] Id. at 9814–9816.

[139] Id. at 9816.

H. Maryland

In the 2016v3 modeling, Maryland is projected to be linked above 1 percent of the NAAQS to three nonattainment receptors and one maintenance-only receptor. It is also linked to three violating-monitor maintenance receptors. Its highest-level contribution is 1.28 ppb to New Haven County, Connecticut (AQS Site ID 090099002). A full summary of Maryland's October 16, 2019, SIP submission was provided in the proposed SIP submission disapproval.[140] The state did not conduct an adequate Step 3 analysis.[141] The State included an insufficient evaluation of additional emissions control opportunities in its SIP submission.[142] Further, as explained in Section V.B.9, states may not rely on non-SIP measures to meet SIP requirements, and reliance on prior transport FIPs such as the CSAPR Update is not a sufficient analysis at Step 3.[143] The EPA also confirmed in the proposed SIP submission disapproval that state emissions controls and regulations identified by Maryland were generally included in the 2016v2 modeling, and yet Maryland was still linked in that modeling.[144] The State included no permanent and enforceable controls in its SIP submission.[145] We provide further response to comments regarding Maryland's SIP submission in the RTC document. The EPA is finalizing disapproval of Maryland's interstate transport SIP submission for the 2015 ozone NAAQS.

I. Michigan

In the 2016v3 modeling, Michigan is projected to be linked above 1 percent of the NAAQS to four nonattainment receptors and six maintenance-only receptors. It is also linked to eight violating-monitor maintenance receptors. Its highest-level contribution is 1.59 to Sheboygan County, Wisconsin (AQS Site ID 551170006). A full summary of Michigan's March 5, 2019, SIP submission was provided in the proposed SIP submission disapproval.[146] The EPA disagrees with Michigan's arguments for application of a higher contribution threshold than 1 percent of the NAAQS as well as criticisms of a 1 percent of the NAAQS contribution threshold at Step 2.[147] The EPA further addresses technical comments on the 1 percent of the NAAQS contribution threshold in Section V.B.4 and addresses comments regarding the relevance of the PSD SILs in Section V.B.6. The State did not conduct an adequate Step 3 analysis.[148] Michigan argued in its SIP submission that additional controls would be premature and burdensome. However, the State included an insufficient evaluation of additional emissions control opportunities to support such a conclusion.[149] The EPA found technical and legal flaws in Michigan's arguments related to upwind-state obligations as to maintenance-only receptors, international emissions, relative contribution, apportionment, and upwind versus downwind-state responsibilities.[150] The EPA further addresses the topics of mobile sources and international emissions in Sections V.C.1 and V.C.2, respectively. The EPA also confirmed in the proposed SIP submission disapproval that the EGU retirements identified by Michigan as not included in the 2011-based EPA modeling, as well as various Federal rules, were included in the 2016v2 modeling, and yet Michigan was still linked in that modeling.[151] The State included no permanent and enforceable emissions controls in its SIP submission.[152] We provide further response to comments regarding Michigan's SIP submission in the RTC document. The EPA is finalizing disapproval of Michigan's interstate transport SIP submission for the 2015 ozone NAAQS.

J. Minnesota

In the 2016v3 modeling, Minnesota is projected to be linked above 1 percent of the NAAQS to one maintenance-only receptor. It is not linked to a violating-monitor maintenance-only receptor. Its highest-level contribution is 0.85 ppb to Cook County, Illinois (AQS Site ID 170310001). A full summary of Minnesota's October 1, 2018, SIP submission was provided in the proposed SIP submission disapproval.[153] Because Minnesota was not projected to be linked to any receptor in 2023 in the EPA's 2011-based modeling, comments argued that the EPA must approve the SIP submission and not rely on new modeling. The EPA responds to these comments in Section V.A.4. Although the EPA acknowledges that Minnesota's Step 3 analysis was insufficient in part because the State assumed it was not linked at Step 2, this is ultimately inadequate to support a conclusion that the State's sources do not interfere with maintenance of the 2015 ozone NAAQS in other states in light of more recent air quality analysis.[154] The State included no permanent and enforceable emissions controls in its SIP submission.[155] We provide further response to comments regarding Minnesota's SIP submission in the RTC document. Although EPA proposed to disapprove both prong 1 and prong 2 of Minnesota's SIP submission, the present record, including the results of the 2016v3 modeling, indicates that Minnesota is not linked to any nonattainment receptors.[156] The EPA is finalizing a partial approval of Minnesota's interstate transport SIP submission for the 2015 ozone NAAQS as to prong 1 and a partial disapproval as to prong 2.

K. Mississippi

In the 2016v3 modeling, Mississippi is projected to be linked above 1 percent of the NAAQS to one nonattainment receptor and two maintenance-only receptors. It is also linked to eight violating-monitor maintenance receptors. Its highest-level contribution is 1.32 ppb to Galveston County, Texas (AQS Site ID 481671034). A full summary of Mississippi's September 3, 2019, SIP submission was provided in the proposed SIP submission disapproval.[157] In its submission, Mississippi advocated for discounting receptors through use of historical data trends. The EPA finds Mississippi's approach is not adequately justified.[158] In the 2011-based modeling, Mississippi's contribution to receptors was above 1 percent of the NAAQS, but below 1 ppb. The EPA disagrees with Mississippi's arguments for application of a higher contribution threshold than

[155] Id. at 9869.

[156] The EPA received a comment that it would be arbitrary and capricious for the EPA to finalize a full disapproval of Tennessee's good neighbor SIP submission (both prong 1 and prong 2) if EPA concluded the state is linked only to a maintenance-only receptor (prong 2). EPA is deferring final action on Tennessee's good neighbor SIP submission, but in reviewing linkages in the 2016v3 modeling we determined that Minnesota and Wisconsin are not linked above 1 percent of the NAAQS to any nonattainment receptors (prong 1) but are linked to maintenance-only receptors (prong 2); these states are receiving partial approvals and partial disapprovals.

[157] 87 FR 9554.

[158] Id. at 9556.

1 percent of the NAAQS at Step 2,[159] and further addresses the relevance of the PSD SILs in Section V.B.6. The state did not conduct a Step 3 analysis.[160] The State included no evaluation of additional emissions control opportunities in its SIP submission.[161] The State included no permanent and enforceable emissions controls in its SIP submission.[162] We provide further response to comments regarding Mississippi's SIP submission in the RTC document. The EPA is finalizing disapproval of Mississippi's interstate transport SIP submission for the 2015 ozone NAAQS.

L. Missouri

In the 2016v3 modeling, Missouri is projected to be linked above 1 percent of the NAAQS to one nonattainment receptor and three maintenance-only receptors. It is also linked to five violating-monitor maintenance receptors. Its highest-level contribution is 1.87 ppb to Sheboygan County, Wisconsin (AQS Site ID 551170006). A full summary of Missouri's June 10, 2019, SIP submission was provided in the proposed SIP submission disapproval.[163] In its submission, Missouri advocated for discounting certain maintenance receptors through use of historical data trends. The EPA finds Missouri's approach is not adequately justified.[164] The EPA disagrees with Missouri's arguments for application of a higher contribution threshold than 1 percent of the NAAQS at Step 2, and further addresses comments regarding the August 2018 memorandum in Section V.B.7.[165] The State did not conduct a Step 3 analysis.[166] The State included no evaluation of additional emissions control opportunities in its SIP submission.[167] The State included no permanent and enforceable emissions controls in its SIP submission.[168] We provide further response to comments regarding Missouri's SIP submission in the RTC document. The EPA is finalizing disapproval of Missouri's June 10, 2019, interstate transport SIP submission for the 2015 ozone NAAQS.

M. Nevada

In the 2016v3 modeling, Nevada is projected to be linked above 1 percent of the NAAQS to three nonattainment receptors and one maintenance-only receptor. It is also linked to one violating-monitor maintenance receptor. Its highest-level contribution is 1.13 ppb to Weber County, Utah (AQS Site ID 490570002). A full summary of Nevada's October 1, 2018, SIP submission was provided in the proposed SIP submission disapproval.[169] Because Nevada was not projected to be linked to any receptor in 2023 in the EPA's 2011-based modeling, commenters on the proposed SIP submission disapproval argued that the EPA must approve the SIP submission and not rely on new modeling. The EPA responds to these comments in Section V.A.4. The EPA also responds to technical criticisms of the 1 percent of the NAAQS contribution threshold and the relevance of the PSD SILs in Section V.B.4 and in Section V.B.6, respectively. The State did not conduct a Step 3 analysis.[170] The State included no evaluation of additional emissions control opportunities in its SIP submission.[171] The State included no additional emissions controls in its SIP submission.[172] We provide response to comments specific to interstate transport policy in the western U.S. in Section V.C.3. We provide further response to comments regarding Nevada's SIP submission in the RTC document. The EPA is finalizing disapproval of Nevada's interstate transport SIP submission for the 2015 ozone NAAQS.

N. New Jersey

In the 2016v3 modeling, New Jersey is projected to be linked above 1 percent of the NAAQS to three nonattainment receptors and one maintenance-only receptor. It is also linked to three violating-monitor maintenance receptors. Its highest-level contribution is 8.38 ppb to Fairfield County, Connecticut (AQS Site ID 090019003). A full summary of New Jersey's May 13, 2019, SIP submission was provided in the proposed SIP submission disapproval.[173] The State did not conduct an adequate Step 3 analysis.[174] New Jersey argued in its SIP submission that existing controls were sufficient to address the State's good neighbor obligations. However, the State included an insufficient evaluation of additional emissions control opportunities to support such a conclusion.[175] The State's reliance on the cost-effectiveness threshold in the CSAPR Update is insufficient for a more protective NAAQS.[176] The State included no permanent and enforceable emissions controls in its SIP submission.[177] We provide further response to comments regarding New Jersey's SIP submission in the RTC document. The EPA is finalizing disapproval of New Jersey's interstate transport SIP submission for the 2015 ozone NAAQS.

O. New York

In the 2016v3 modeling, New York is projected to be linked above 1 percent of the NAAQS to three nonattainment receptors and one maintenance-only receptor. It is also linked to two violating-monitor maintenance receptors. Its highest-level contribution is 16.10 ppb to Fairfield County, Connecticut (AQS Site ID 090010017). A full summary of New York's September 25, 2018, SIP submission was provided in the proposed SIP submission disapproval.[178] The state did not conduct an adequate Step 3 analysis.[179] New York argued in its SIP submission that existing controls were sufficient to address the State's good neighbor obligations. However, the state included an insufficient evaluation of additional emissions control opportunities to support such a conclusion.[180] The State's reliance on the cost-effectiveness threshold in the CSAPR Update is insufficient for the more protective 2015 ozone NAAQS.[181] The State included no permanent and enforceable emissions controls in its SIP submission.[182] We provide further response to comments regarding New York's SIP submission in the RTC document. The EPA is finalizing disapproval of New York's interstate transport SIP submission for the 2015 ozone NAAQS.

P. Ohio

In the 2016v3 modeling, Ohio is projected to be linked above 1 percent of the NAAQS to four nonattainment receptors and five maintenance-only

[168] We note that in comments, Missouri indicated its intent to submit a new SIP submission to the EPA, which would re-evaluate good neighbor obligations based on its 2016v2 linkages and provide an analysis that would include emissions reductions requirements. The EPA received this submission on November 1, 2022. The EPA explains its consideration of this new submission as separate SIP submission in the RTC document for this final action.

receptors. It is also linked to nine violating-monitor maintenance receptors. Its highest-level contribution is 2.05 ppb to Fairfield County, Connecticut (AQS Site ID 090019003). A full summary of Ohio's September 28, 2018, SIP submission was provided in the proposed SIP submission disapproval.[183] In its submission, Ohio advocated for use of the Texas Commission on Environmental Quality (TCEQ)'s definition of maintenance receptors. The EPA finds that TCEQ's definition is legally and technically flawed,[184] and as a result Ohio's approach is also not adequately justified.[185] The EPA further evaluates TCEQ's technical arguments in a TSD prepared by regional modeling staff.[186] The EPA disagrees with Ohio's arguments for application of a higher contribution threshold than 1 percent of the NAAQS at Step 2.[187] The EPA responds to technical criticisms of the 1 percent of the NAAQS contribution threshold in Section V.B.4. The State did not conduct an adequate Step 3 analysis.[188] The State included an insufficient evaluation of additional emissions control opportunities in its SIP submission.[189] The EPA found technical deficiencies in Ohio's unsubstantiated claims that emissions are overestimated.[190] The EPA also confirmed in the proposed SIP submission disapproval that several EGU and non-EGUs identified by Ohio were included in the 2016v2 modeling, and yet Ohio was still linked in that modeling.[191] The EPA summarizes the emissions inventories used in the 2016v3 modeling in Section III.A. Further, as explained in Section V.B.9, states may not rely on non-SIP measures to meet SIP requirements, and reliance on prior transport FIPs such as the CSAPR Update is not a sufficient analysis at Step 3.[192] The EPA finds legal flaws and deficiencies in Ohio's arguments related to upwind versus downwind-state responsibilities, the role of international emissions, relative contribution, and overcontrol.[193] The EPA discusses international emissions in Section V.C.2. The EPA disagrees with Ohio's arguments related to mobile sources.[194] We further address this topic in Section V.C.1. Ohio also argued in its SIP submission that it had already implemented all cost-effective controls. However, the state included no evaluation of additional emissions control opportunities to support such a claim.[195] Further, the State's reliance on the cost-effectiveness threshold in the CSAPR Update is insufficient for the more protective 2015 ozone NAAQS.[196] The State included no permanent and enforceable emissions controls in its SIP submission.[197] We provide further response to comments regarding Ohio's SIP submission in the RTC document. The EPA is finalizing disapproval of Ohio's interstate transport SIP submission for the 2015 ozone NAAQS.

Q. Oklahoma

In the 2016v3 modeling, Oklahoma is projected to be linked above 1 percent of the NAAQS to one nonattainment receptor and one maintenance-only receptor. It is also linked to eight violating-monitor maintenance receptors. Its highest-level contribution is 1.01 ppb to Denton County, Texas (AQS Site ID 481210034). A full summary of Oklahoma's October 25, 2018, SIP submission was provided in the proposed SIP submission disapproval.[198] In its submission, Oklahoma advocated for use of TCEQ's definition of maintenance receptors and modeling to discount receptors in Texas. The EPA finds that TCEQ's definition is legally and technically flawed [199] and, as a result, Oklahoma's approach is also not adequately justified.[200] The EPA further evaluates TCEQ's technical arguments in the EPA Region 6 2015 8-Hour Ozone Transport SIP Proposal TSD (Evaluation of TCEQ Modeling TSD) prepared by regional modeling staff.[201] Comments argued against the use of updated modeling where linkages in the EPA's 2011-based modeling and later iterations of EPA modeling differ. The EPA addressed the change in identified linkages between the 2011-based modeling and the 2016v2 modeling in the proposed SIP disapproval,[202] and further responds to comments on the use of updated modeling in Section V.A.4. The EPA disagrees with Oklahoma's arguments for application of a higher contribution threshold than 1 percent of the NAAQS at Step 2 [203] and further addresses comments regarding the relevance of the PSD SILs in Section V.B.6. The State did not conduct an adequate Step 3 analysis.[204] Oklahoma argued in its SIP submission that it had already implemented all cost-effective controls. However, the State included an insufficient evaluation of additional emissions control opportunities to support such a conclusion.[205] As explained in Section V.B.9, states may not rely on non-SIP measures to meet SIP requirements, and reliance on prior transport FIPs such as the CSAPR Update is not a sufficient analysis at Step 3.[206] Further, the State's reliance on the cost-effectiveness threshold in the CSAPR Update is insufficient for the more protective 2015 ozone NAAQS.[207] The EPA finds legal flaws in Oklahoma's argument related to collective contribution.[208] The State included no permanent and enforceable emissions controls in its SIP submission.[209] We provide further response to comments regarding Oklahoma's SIP submission in the RTC document. The EPA is finalizing disapproval of Oklahoma's interstate transport SIP submission for the 2015 ozone NAAQS.

R. Texas

In the 2016v3 modeling, Texas is projected to be linked above 1 percent of the NAAQS to one nonattainment receptor and nine maintenance-only receptors. It is also linked to ten violating-monitor maintenance-only receptor. Its highest-level contribution is 4.74 ppb to Dona Ana County, New Mexico (AQS Site ID 350130021). A full summary of Texas's August 17, 2018, SIP submission was provided in the proposed SIP submission disapproval,[210] and additional details were provided in the Evaluation of TCEQ Modeling TSD. The EPA identified several technical flaws in TCEQ's modeling and analysis of modeling results.[211] In its submission, Texas advocated for use of its own definition of maintenance receptors and modeling. The EPA finds Texas's approach inadequately justified and

legally and technically flawed.[212] The EPA further evaluated TCEQ's technical arguments in the Evaluation of TCEQ Modeling TSD. In comment on the proposal, Texas pointed to differences in linkages in the EPA's 2011-based modeling and 2016v2 modeling. The EPA addressed the change in identified linkages between the 2011-based modeling and the 2016v2 modeling in the proposed SIP submission disapproval,[213] and further responds to comments on the use of updated modeling in Section V.A.4. The State did not conduct an adequate Step 3 analysis.[214] The State included an insufficient evaluation of additional emissions control opportunities in its SIP submission.[215] The EPA found technical flaws in Texas's arguments related to ''consistent and persistent'' claims and its other assessments, including analysis of back trajectories.[216] The State included no permanent and enforceable emissions controls in its SIP submission.[217] We provide further response to comments regarding Texas's SIP submission in the RTC document. The EPA is finalizing disapproval of Texas's interstate transport SIP submission for the 2015 ozone NAAQS.

S. Utah

In the 2016v3 modeling, Utah is projected to be linked above 1 percent of the NAAQS to three nonattainment receptors and one maintenance-only receptor. It is also linked to four violating-monitor maintenance receptors. Its highest-level contribution is 1.29 ppb to Douglas County, Colorado (AQS Site ID 080350004). A full summary of Utah's January 29, 2020, SIP submission was provided in the proposed SIP submission disapproval.[218] In its submission, Utah argued that certain receptors in Colorado should not be counted as receptors for the purpose of 2015 ozone NAAQS interstate transport, but Utah's explanation is insufficient to discount those receptors.[219] The EPA disagrees with Utah's arguments for application of a higher contribution threshold than 1 percent of the NAAQS at Step 2.[220] Utah suggested in its SIP submission that interstate transport is fundamentally different in the western U.S. than in the eastern U.S., an argument we have previously rejected and respond to further in Section V.C.3.[221] The State did not conduct an adequate Step 3 analysis.[222] The State included an insufficient evaluation of additional emissions control opportunities in its SIP submission.[223] The EPA finds technical and legal flaws in the State's arguments related to relative contribution, international and non-anthropogenic emissions, and the relationship of upwind versus downwind-state responsibilities.[224] The EPA further addresses the topics of international emissions in Section V.C.2 and wildfires in the RTC document. The EPA also confirmed in the proposed SIP submission disapproval that several anticipated controls identified by Utah were included in the 2016v2 modeling, and yet Utah was still linked in that modeling.[225] The State included no permanent and enforceable emissions controls in its SIP submission.[226] We provide further response to comments regarding Utah's SIP submission in the RTC document. The EPA is finalizing disapproval of Utah's interstate transport SIP submission for the 2015 ozone NAAQS.

T. West Virginia

In the 2016v3 modeling, West Virginia is projected to be linked above 1 percent of the NAAQS to three nonattainment receptors and one maintenance-only receptor. It is also linked to four violating-monitor maintenance receptors. Its highest-level contribution is 1.49 ppb to New Haven County, Connecticut (AQS Site ID 090099002). A full summary of West Virginia's February 4, 2019, SIP submission was provided in the proposed SIP submission disapproval.[227] The EPA finds technical and legal flaws in the State's examination of back trajectories and arguments related to mobile sources and international emissions.[228] The EPA further addresses the topics of mobile sources and international emissions in Section V.C.1 and in Section V.C.2, respectively. The State did not conduct an adequate Step 3 analysis.[229] West Virginia argued in its SIP submission that it had already implemented all cost-effective controls. However, the State included an insufficient evaluation of additional emissions control opportunities to support such a conclusion.[230] The EPA also confirmed in the proposed SIP submission disapproval that specific EGU shutdowns identified by West Virginia were included in the 2016v2 modeling, which continued to show West Virginia was linked at Step 2.[231] As explained in Section V.B.9, a state may not rely on non-SIP measures to satisfy SIP requirements, and reliance on prior transport FIPs such as the CSAPR Update is not a sufficient analysis at Step 3.[232] Further, the State's reliance on the cost-effectiveness threshold in the CSAPR Update is insufficient for a more protective NAAQS.[233] The State included no permanent and enforceable emissions controls in its SIP submission.[234] We provide further response to comments regarding West Virginia's SIP submission in the RTC document. The EPA is finalizing disapproval of West Virginia's interstate transport SIP submission for the 2015 ozone NAAQS.

U. Wisconsin

In the 2016v3 modeling, Wisconsin is projected to be linked above 1 percent of the NAAQS to three maintenance-only receptors. It is also linked to five violating-monitor maintenance receptors. Its highest-level contribution is 2.86 ppb to Cook County, Illinois (AQS Site ID 170314201). A full summary of Wisconsin's September 14, 2018, SIP submission was provided in the proposed SIP submission disapproval.[235] The State did not assess in its SIP submission whether the state was linked at Step 2,[236] and did not conduct an adequate Step 3 analysis.[237] The State included an insufficient evaluation of additional emissions control opportunities.[238] Further, as explained in Section V.B.9, reliance on prior transport FIPs such as the CSAPR Update is not a sufficient analysis at Step 3.[239] The EPA found additional inadequacies and legal flaws in Wisconsin's submission.[240] The State included no permanent and enforceable emissions controls in its SIP submission.[241] We provide further response to comments regarding

Wisconsin's SIP submission in the RTC document. Although EPA proposed to disapprove both prong 1 and prong 2 of Wisconsin's SIP submission, the present record, including the results of the 2016v3 modeling, indicates that Wisconsin is not linked to any nonattainment receptors.[242] The EPA is finalizing a partial approval of Wisconsin's interstate transport SIP submission for the 2015 ozone NAAQS as to prong 1 and a partial disapproval as to prong 2.

V. Response to Key Comments

The EPA received numerous comments on the proposed action which are summarized in the RTC document along with the EPA's responses to those comments in Docket ID No. EPA–HQ–OAR–2021–0663. Each comment in its entirety is available in the relevant regional docket(s) for this action.[243] The following sections summarize key comments and the EPA's responses.

A. SIP Evaluation Process

1. Relationship Between Timing of Proposals To Disapprove SIPs and Promulgate FIPs

Comment: Comments alleged generally that the timing of the EPA's proposed actions on the SIP submissions in relation to proposed FIPs was unlawful, unfair, or both. Some comments claimed that the sequence of the EPA's actions is improper, unreasonable, or bad policy. Several commenters asserted that because the EPA proposed FIPs (or, according to some, promulgated FIPs, which is not factually correct) prior to finalizing disapproval of the state SIP submission, the EPA allegedly exceeded its statutory authority and overstepped the states' primary role in addressing the good neighbor provision under CAA section 110.[244]

EPA Response: The EPA disagrees. The EPA has followed the Clean Air Act provisions, which prescribe specified maximum amounts of time for states to make SIP submissions, for the EPA to act on those submissions, and for the EPA to promulgate FIPs if necessary, but do not prohibit the EPA from acting before that time elapses. Nothing relieves the EPA from its statutory obligation to take final action on complete SIP submissions before the Agency within the timeframes prescribed by the statute.[245] The EPA's proposed FIP does not constitute the ''promulgation'' of a FIP because the proposed FIP is not a final action that imposes any requirements on sources or states. And although the EPA's FIP authority is not at issue in this action, the EPA notes the Agency has been clear that it will not finalize a FIP for any state until predicate authority is established for doing so under CAA section 110(c)(1). 87 FR 20036, 20057 (April 6, 2022) (''The EPA is proposing this FIP action now to address twenty-six states' good neighbor obligations for the 2015 ozone NAAQS, but the EPA will not finalize this FIP action for any state unless and until it has issued a final finding of failure to submit or a final disapproval of that state's SIP submission.''). The EPA strongly disagrees that *proposing* a FIP prior to proposing or finalizing disapproval of a SIP submission oversteps the Agency's authority. Indeed, the ability to propose a FIP before finalizing a SIP disapproval follows ineluctably from the structure of the statute, which, as the Supreme Court recognized in *EME Homer City,* does not oblige the EPA ''to wait two years or postpone its [FIP] action even a single day.'' 572 U.S. at 509. If the EPA can finalize a FIP immediately upon disapproving a SIP, then surely the EPA must have the authority to propose that FIP before taking final action on the SIP submission. *Accord Oklahoma* v. *U.S. EPA,* 723 F.3d 1201, 1223 (10th Cir. 2013).

It is true that the EPA would not be legally authorized to *finalize* a FIP for any state unless and until the EPA formally *finalizes* a disapproval of that state's SIP submission (or makes a finding of failure to submit for any state that fails to make a complete SIP submission), per CAA section 110(c), but the EPA has not yet finalized a FIP for any state for good neighbor obligations for the 2015 ozone NAAQS. Further, the sequencing of our actions here is consistent with the EPA's past practice in our efforts to timely address good neighbor obligations. For example, at the time the EPA proposed the CSAPR Update FIPs in December of 2015, we had not yet proposed action on several states' SIP submissions but finalized those SIP disapproval actions prior to finalization of the FIP.[246]

Additional comments on cooperative federalism are addressed in Section V.B.5.

Further, The D.C. Circuit in *Wisconsin* held that states and the EPA are obligated to fully address good neighbor obligations for ozone ''as expeditiously as practical'' and in no event later than the next relevant downwind attainment dates found in CAA section 181(a),[247] and states and the EPA may not delay implementation of measures necessary to address good neighbor requirements beyond the next applicable attainment date without a showing of impossibility or necessity.[248] It is important for the states and the EPA to assure that necessary emissions reductions are achieved, to the extent feasible, by the 2023 ozone season to assist downwind areas with meeting the August 3, 2024, attainment deadline for Moderate nonattainment areas. Further, the D.C. Circuit in *Wisconsin* emphasized that the EPA has the authority under CAA section 110 to structure its actions so as to ensure necessary reductions are achieved by the downwind attainment

[242] The EPA received a comment that it would be arbitrary and capricious for the EPA to finalize a full disapproval of Tennessee's good neighbor SIP submission (both prong 1 and prong 2) if EPA concluded the State is linked only to a maintenance-only receptor (prong 2).The EPA is deferring final action on Tennessee's good neighbor SIP submission, but in reviewing linkages in the 2016v3 modeling we determined that Minnesota and Wisconsin are not linked above 1 percent of the NAAQS to any nonattainment receptors (prong 1) but are linked to maintenance-only receptors (prong 2); these States are receiving partial approvals and partial disapprovals.

[243] *See* the memo ''Regional Dockets Containing Additional Supporting Materials for Final Action on 2015 Ozone NAAQS Good Neighbor SIP Submissions'' in the docket for this action, for a list of all regional dockets.

[244] The EPA notes the commenters' reference to FIPs is to proposed good neighbor FIPs for the 2015 ozone NAAQS that were proposed separately from this rulemaking action. 87 FR 20036 (April 6, 2022).

[245] Although the EPA anticipates responding to comments related to the EPA's FIP authority in a separate FIP rulemaking, the EPA notes with regard to the procedural timing concerns raised in comments on this action that the Supreme Court confirmed in *EME Homer City Generation,* ''EPA is not obliged to wait two years or postpone its action even a single day: The Act empowers the Agency to promulgate a FIP 'at any time' within the two-year limit.'' 572 U.S. 489 at 509. The procedural timeframes under CAA section 110 do not function to establish a norm or expectation that the EPA must or should use the full amount of time allotted, particularly when doing so would place the Agency in conflict with the more ''central'' statutory objective of meeting the NAAQS attainment deadlines in the Act. *EME Homer City,* 572 U.S. 489, 509 (2014). *See also Wisconsin,* 938 F.3d at 318, 322; *Sierra Club* v. *EPA,* 294 F.3d 155, 161 (D.C. Cir. 2002) (*Sierra Club*).

[246] The proposed CSAPR Update was published on December 3, 2015, and included proposed FIPs for Indiana, Louisiana, New York, Ohio, Texas, and Wisconsin. 80 FR 75705. At that time, the EPA had not yet even proposed action on good neighbor SIP submissions for the 2008 ozone NAAQS from Indiana, Louisiana, New York, Ohio, Texas, and Wisconsin; however, the EPA subsequently proposed and finalized these disapprovals before finalizing the CSAPR Update FIPs, published on October 26, 2016 (81 FR 74504). *See* 81 FR 38957 (June 15, 2016) (Indiana); 81 FR 53308 (August 12, 2016) (Louisiana); 81 FR 58849 (August 26, 2016) (New York); 81 FR 38957 (June 15, 2016) (Ohio); 81 FR 53284 (August 12, 2016) (Texas); 81 FR 53309 (August 12, 2016) (Wisconsin).

[247] *Wisconsin,* 938 F.3d at 313–14 (citing *North Carolina,* 531 F.3d at 911–12.

[248] *See Wisconsin,* 938 F.3d at 320.

dates,[249] the next of which for the 2015 ozone NAAQS is now the Moderate area attainment date of August 3, 2024.[250] The court pointed out that the CAA section 110 schedule of SIP and FIP deadlines is procedural whereas the attainment schedule is ''central to the regulatory scheme[.]'' [251] Thus, the sequence and timing of the EPA's action in disapproving these SIP submissions is informed by the need to ensure that any necessary good neighbor obligations identified in the separate FIP rulemaking are implemented as expeditiously as practicable and no later than the next attainment date. As explained in our proposed disapproval, analysis (and, if possible, implementation) of good neighbor obligations should begin in the 2023 ozone season. *See, e.g.,* 87 FR 9798, 9801–02 (Feb. 22, 2022). Indeed, states' and the EPA's analysis would have been more appropriately aligned with 2020, rather than 2023 (as had been presented in the EPA's March 2018 memorandum [252]), corresponding with the 2021 Marginal area attainment date. However, that clarification in legal obligations was not established by case law until 2020. *See Maryland,* 958 F.3d at 1203–04.

In short, nothing in the language of CAA section 110(c) prohibits the EPA from proposing a FIP as a backstop, to be finalized and implemented only in the event that a SIP submission is first found to be deficient and final disapproval action on the SIP submission is taken. Such an approach is a reasonable and prudent means of assuring that the statutory obligation to reduce air pollution affecting the health and welfare of those living in downwind states is implemented without delay, either via a SIP, or where such plan is deficient, via a FIP. The sequencing of the EPA's actions here is therefore reasonably informed by its legal obligations under the CAA, including in recognition of the fact that the implementation of necessary emissions reductions to eliminate significant contribution and thereby protect human health and welfare is already several years delayed. The EPA shares additional responses related to the timing of 2015 ozone NAAQS good neighbor actions in Section V.A.

Comment: Some comments allege the EPA is depriving States of the opportunity to target specific emissions reductions opportunities, or the opportunity to revise their submissions at any point in the future.

EPA Response: The EPA disagrees. The EPA has repeatedly emphasized that states have the freedom at any time to develop a revised SIP submission and submit that to the EPA for approval, and this remains true. *See* 87 FR 20036, 20051 (April 6, 2022); 86 FR 23054, 23062 (April 30, 2021); 81 FR 74504, 74506 (Oct. 26, 2016). In the proposed FIPs, as in prior transport actions, the EPA discusses a number of ways in which states could take over or replace a FIP, *see* 87 FR 20036, 20149–51 (Section VII.D: ''Submitting A SIP''); *see also id.* at 20040 (noting as one purpose in proposing the FIP that ''this proposal will provide states with as much information as the EPA can supply at this time to support their ability to submit SIP revisions to achieve the emissions reductions the EPA believes necessary to eliminate significant contribution''). If, and when, the EPA receives a SIP submission that satisfies the requirements of CAA section 110(a)(2)(D)(i)(I), the Agency will take action to approve that SIP submission.

Comment: Some commenters assert that the EPA is disapproving SIP submissions for the sole purpose of pursuing an alleged objective of establishing nation-wide standards in FIPs. Other commenters point to the proposed FIPs to make arguments that the EPA's decision to finalize disapproval of the SIPs is an allegedly foregone conclusion or that the EPA has allegedly failed to provide the opportunity for meaningful public engagement on the proposed disapproval of the SIPs.

EPA Response: The EPA disagrees as the facts do not support this assertion. To date, the EPA has approved 24 good neighbor SIPs for the 2015 ozone NAAQS: Alaska,[253] Colorado,[254] Connecticut,[255] Delaware,[256] District of Columbia,[257] Florida,[258] Georgia,[259] Hawaii,[260] Idaho,[261] Iowa,[262] Kansas,[263] Maine,[264] Massachusetts,[265] Montana,[266] Nebraska,[267] New Hampshire,[268] North Carolina,[269] North Dakota,[270] Oregon,[271] Rhode Island,[272] South Carolina,[273] South Dakota,[274] Vermont,[275] and Washington.[276]

The policy judgments made by the EPA in all actions on 2015 ozone NAAQS good neighbor SIP submissions, including approval actions, reflect consistency with relevant good neighbor case law and past agency practice implementing the good neighbor provision as reflected in the original CSAPR, CSAPR Update, Revised CSAPR Update, and related rulemakings. Employing a nationally consistent approach is particularly important in the context of interstate ozone transport, which is a regional-scale pollution problem involving many smaller contributors. Effective policy solutions to the problem of interstate ozone transport dating back to the NO_X SIP Call [63 FR 57356 (October 27, 1998)] have necessitated the application of a uniform framework of policy judgments to ensure an ''efficient and equitable'' approach. *See EME Homer City,* 572 U.S. at 519. In any case, the approach of the proposed transport FIP is not the subject of this SIP disapproval. This rulemaking does not impose any specific emissions control measures on the states. Nor is the EPA disapproving these SIP submittals because they did not follow exactly the control strategies in the proposed FIP—the EPA has repeatedly indicated openness to alternative approaches to addressing interstate pollution obligations, but for reasons explained elsewhere in the rulemaking record, the EPA finds that none of the states included in this action submitted approvable approaches to addressing those obligations.

The EPA disputes the contentions that the FIP proposal itself indicates that the EPA did not earnestly examine the SIP submissions for compliance with the CAA or have an appropriate rationale

[249] *Wisconsin,* 938 F.3d at 318 (''When EPA determines a State's SIP is inadequate, the EPA presumably must issue a FIP that will bring that State into compliance before upcoming attainment deadlines, even if the outer limit of the statutory timeframe gives the EPA more time to formulate the FIP.'') for proposing to disapprove certain SIP submissions. The EPA also disputes that the FIP proposal indicates that the EPA did not intend to consider comments on the proposed disapprovals. Comments making claims the EPA did not follow proper administrative procedure have been submitted utilizing the very notice and comment process these comments claim the EPA is skipping, and these claims are factually unsupported. Comments related to the length of the comment period and claims of ''pretext'' are addressed in the RTC document.

Comment: Several comments pointed out how hard many states have worked to develop an approvable SIP submission.

EPA Response: The EPA acknowledges and appreciates states' efforts to develop approvable SIPs. Cooperative federalism is a cornerstone of CAA section 110, and the EPA strives to collaborate with its state partners. The timing of the EPA's 2015 ozone NAAQS good neighbor actions is not in any way intended to call into question any state's commitment to develop approvable SIPs. The EPA evaluated each SIP submission on its merits. The EPA relies on collaboration with state air agencies to ensure SIP submissions are technically and legally defensible, and the Agency's action here is in no way meant to undermine that collaboration between state and Federal partners respecting SIP development.

Comment: Several comments make various arguments about when the EPA can finalize FIPs. Some commenters argue that CAA section 110(c)(1) guarantees states an additional two years to correct their SIP submissions before the EPA finalizes a FIP. Others argue that the notice and comment requirements of the Administrative Procedures Act mandate that the EPA finalize a SIP submission disapproval before proposing a FIP. One commenter suggested that a state must be allowed to fully exhaust its judicial remedies to challenge a SIP submission disapproval before the EPA can promulgate a FIP. Commenters also raise concerns about the analysis and requirements in the proposed FIPs.

EPA Response: Comments opining on when the EPA is legally authorized to propose or finalize a FIP are outside the scope of this action. While the EPA acknowledges that the Agency has no obligation or authority to finalize a FIP until finalizing a disapproval of a SIP submission or determining that a state failed to submit a complete SIP submission (CAA section 110(c)(1)), this action is limited to determining whether the covered SIP submissions meet the requirements of CAA section 110(a)(2)(D)(i)(I). For the same reason, comments criticizing specific substantive requirements or implementation timelines in the proposed FIPs are beyond the scope of this action.

2. Requests for Additional Time To Revise SIP Submissions

Comment: Some commenters argue that the EPA must or should delay action on these SIP submissions so that states can reexamine and resubmit SIP submissions. Other commenters argue that states must be given more time to re-examine and resubmit their SIP submission for various reasons, including the substantive requirements in the proposed FIPs.

EPA Response: The EPA notes that there is no support in the Clean Air Act for such a delay. CAA section 110(a)(1) requires states to adopt and submit SIP submissions meeting certain requirements including the requirements of CAA section 110(a)(2)(D)(i)(I), ''within 3 years (or such shorter period as the Administrator prescribe) after the promulgation of a national primary ambient air quality standard (or any revision thereof).'' CAA section 110(a)(1). The submission deadline clearly runs from the date of promulgation of the NAAQS, which for the 2015 ozone NAAQS was October 1, 2015. 80 FR 65291 (Oct. 26, 2015). In addition, while the Administrator is given authority to prescribe a period shorter than three years for the states to adopt and submit such SIP submissions, the Act does not give the Administrator authority to lengthen the time allowed for CAA section 110(a)(2) submissions. And the EPA would be in violation of court-ordered deadlines if it deferred taking final action beyond January 31, 2023, for all but two of the states covered by this action.[277]

Comments asserting that the EPA must give more time to states to correct deficiencies and re-submit conflict with the controlling caselaw in that they would elevate the maximum timeframes allowable within the procedural framework of CAA section 110 over the attainment schedule of CAA section 181 that the D.C. Circuit has now held multiple times must be the animating focus in the timing of good neighbor obligations. The D.C. Circuit in *Wisconsin* held that states and the EPA are obligated to fully address good neighbor obligations for ozone ''as expeditiously as practical'' and in no event later than the next relevant downwind attainment dates found in CAA section 181(a),[278] and the EPA may not delay implementation of measures necessary to address good neighbor requirements beyond the next applicable attainment date without a showing of impossibility or necessity.[279] Further, the court pointed out that the CAA section 110 schedule of SIP and FIP deadlines is procedural, and while the EPA has complied with the mandatory sequence of actions required under section 110 here, we are mindful of the court's observation that, as compared with the fundamental substantive obligations of title I of the CAA to attain and maintain the NAAQS, the maximum timeframes allotted under section 110 are less ''central to the regulatory scheme[.]'' [280]

Comment: Other comments take the position that states are owed a second opportunity to submit SIP submissions before the EPA takes final action for various reasons, including claims that the EPA failed to issue adequate guidance or is otherwise walking back previously issued guidance. They allege that a state cannot choose controls to eliminate significant contribution until the EPA quantifies the contribution. Other comments argue that the EPA should not or cannot base the disapprovals on alleged shifts in policy that occurred after the Agency received the SIP submissions.

EPA Response: The EPA disagrees that the Agency was required to issue guidance or quantify individual states' level of significant contribution for 2015 ozone NAAQS good neighbor obligations, because as noted in *EME Homer City,* the Supreme Court clearly held that ''nothing in the statute places EPA under an obligation to provide specific metrics to States before they undertake to fulfill their good neighbor obligations.'' [281] The Agency issued three memoranda in 2018 to provide modeling results and some ideas to states in the development of their SIP submissions. However, certain aspects of those discussions were specifically

[277] The EPA has no court-ordered deadline to take final action on the good neighbor SIP submission from Alabama dated June 21, 2022, or Utah's good neighbor SIP submission.

[278] *Wisconsin,* 938 F.3d at 313–14 (citing *North Carolina,* 531 F.3d at 911–12). On May 19, 2020, the D.C. Circuit in *Maryland,* applying the *Wisconsin* decision, held that the EPA must assess air quality at the next downwind attainment date, including Marginal area attainment dates, in evaluating the basis for the EPA's denial of a petition under CAA section 126(b). *Maryland,* 958 F.3d at 1203–04.

[279] *See Wisconsin,* 938 F.3d at 320.

[280] *Wisconsin,* 938 F.3d at 322 (''Delaware's argument leans too heavily on the SIP submission deadline. SIP submission deadlines, unlike attainment deadlines, are 'procedural' and therefore not 'central to the regulatory scheme.' '') (citing *Sierra Club,* 294 F.3d at 161).

[281] *EME Homer City,* 572 U.S. at 510.

identified as not constituting agency guidance (especially Attachment A to the March 2018 memorandum, which comprised an unvetted list of outside stakeholders' ideas). Further, states' submissions did not meet the terms of the August or October 2018 memoranda addressing contribution thresholds and maintenance receptors, respectively. (*See* Section V.B for further discussion of these memoranda.) We acknowledge that the EPA reassessed air quality and states' contribution levels through additional modeling before proposing action on these SIP submissions. But that is not in any way an effort to circumvent the SIP/FIP process; rather it is an outcome of the reality that the EPA updated its modeling platform from a 2011 to a 2016 base year and updated its emissions inventory information along with other updates. There is nothing improper in the Agency improving its understanding of a situation before taking action, and the Agency reasonably must be able to act on SIP submissions using the information available at the time it takes such action. Those updates have not uniformly been used to disapprove SIPs—the new modeling for instance supported the approval of Montana's and Colorado's SIPs.[282] Nor has the new modeling prevented states from submitting new SIP submissions based on that modeling. For instance, the State of Alabama withdrew its prior submission in April of 2022, following our proposed disapproval, and submitted a new submission (further updated in June of 2022) analyzing the 2016v2 modeling used at proposal. The EPA is acting on that new submission and evaluating the new arguments the State developed regarding the more recent modeling. Nonetheless, as explained in the EPA's proposed disapproval of Alabama's new submission and in Section IV.A, the new arguments that Alabama has presented in its more recent submission do not lead the EPA to a contrary conclusion that its SIP submission should be approved.[283] This demonstrates two points contrary to commenters' contentions: first, the EPA is following the science and is making nationally consistent determinations at Steps 1 and 2, based on its review of each state's submission; and second, the fact that states made submissions based on the 2011-based modeling results presented in the March 2018 memorandum rather than on the most recent modeling results is not prejudicial to the outcome of the EPA's analysis, as our action on Alabama's more recent submission evaluating the State's arguments with respect to the newer, 2016-based modeling makes clear.

Contrary to commenters' arguments, the EPA had no obligation to issue further guidance, define obligations, or otherwise clarify or attempt to interpret states' responsibilities since the issuance of the 2018 memoranda, prior to acting on these SIP submissions. States themselves were aware or should have been aware of the case law developments in *Wisconsin* and in *Maryland,* which called into question the EPA's use of 2023 as the analytical year in the March 2018 memorandum. Those decisions were issued in 2019 and 2020 respectively, yet no state moved to amend or supplement their SIP submissions with analysis of an earlier analytical year or to otherwise bring their analyses into conformance with those decisions (*e.g.,* through fuller analysis of non-EGU emissions reduction potential or through treatment of international contribution). Given the Supreme Court's 2014 holding in *EME Homer City,* 572 U.S. at 508–510, which reversed a D.C. Circuit holding that the EPA *was* obligated to define good neighbor obligations,[284] states had no reason to expect the EPA would be obligated to issue further guidance to clarify requirements in the wake of those decisions. The EPA agrees with those commenters who point out that states have the first opportunity to assess and address obligations in implementing the NAAQS, but with that understanding in mind, it is notable that prior to the proposed disapprovals in February of 2022, no state moved to amend or supplement their SIP submission as the case law on good neighbor obligations evolved or in response to new modeling information as it became available.

Further, the EPA has evaluated state SIP submissions on the merits of what is contained in the submission, not the use of any particular modeling platform. The EPA disagrees with commenters' assertions that the EPA has proposed disapproval of a state's proposed SIP due to the use of a particular modeling platform. As noted previously, the EPA approved state SIP submissions that have used the earlier modeling. The EPA did not reach its conclusion to disapprove states' SIP submissions based on the use of the 2016v2 emissions platform standing alone. Use of that platform, or any other modeling platform, is not *ipso facto* grounds for disapproval at all. As evident in the proposed disapprovals and summarized in Section IV, the EPA evaluated the SIP submissions based on the merits of the arguments put forward in each SIP submission.

3. Alleged Harm to States Caused by Time Between SIP Submission and the EPA's Action

Comment: Many comments pointed to the EPA's statutory deadlines to take action on the SIP submissions to argue that the EPA's delay harmed the upwind state's interests because now the EPA may conclude they need to reduce their emissions to satisfy their good neighbor obligations in the separate FIP rulemaking whereas had the EPA acted by statutory deadlines using the older modeling, they might have had their SIP submissions approved. Some commenters suggest that the EPA never gave the state SIP submissions the appropriate review or suggest that the EPA's review of the SIP submissions was prejudiced by the FIP it had proposed.

EPA Response: The EPA acknowledges that the Agency's statutory deadlines to take final action on these SIP submissions generally fell in 2020 and 2021. However, the delay in acting caused no prejudice to the upwind states. First, this action to disapprove SIP submissions itself will not impose any requirements or penalties on any state or sources within that state. Second, these delays have primarily had the effect of deferring relief to downwind states and their citizens from excessive levels of ozone pollution under the good neighbor provision. Further, the EPA has generally had a practice of correcting its action on good neighbor SIP submittals if later information indicates that a prior action was in error—thus, it is not the case that simply having obtained an approval based on earlier modeling would have meant a state would be forever insulated from later being subject to corrective or remedial good neighbor actions. *See, e.g.,*86 FR 23056, 23067–68 (April 30, 2021) (error correcting Kentucky's approval to a disapproval and promulgating FIP addressing Kentucky's outstanding 2008 ozone NAAQS good neighbor obligations); 87 FR 20036, 20041 (April 6, 2022) (proposing error correction for Delaware's 2015 ozone NAAQS SIP approval to a disapproval based on updated air quality modeling). Finally, there is no basis in the CAA to use the Agency's own delay as a basis to nullify

[282] 87 FR 6095, 6097 at n. 15 (February 3, 2022) (Montana proposal); 87 FR 27050, 27056 (May 6, 2022) (Colorado, proposal), 87 FR 61249 (October 11, 2022) (Colorado, final).

[283] 87 FR 64412 (October 25, 2022).

[284] *EME Homer City Generation, L.P.* v. *EPA,* 696 F.3d 7 (D.C. Cir. 2012) (*EME Homer City I*).

the authority granted in the Act to address the nation's air pollution problems, as the statute itself contains other forms of adequate remedy. CAA section 304(a)(2) provides for judicial recourse where there is an alleged failure by the agency to perform a nondiscretionary duty, and that recourse is for the Agency to be placed on a court-ordered deadline to address the relevant obligations. *Accord Oklahoma,* 723 F.3d at 1223–24; *Montana Sulphur and Chemical Co.* v. *U.S. EPA,* 666 F.3d 1174, 1190–91 (9th Cir. 2012).

Comment: Some comments contend that the EPA's delay in acting on SIP submissions was a deliberate attempt to circumvent the SIP/FIP process, unduly burden the states, or to defer making information available to states. Comments allege that the EPA intentionally stalled an evaluative action until the perceived ''facts'' of the situation changed such that the analyses submitted by states were rendered outdated.

EPA Response: The EPA disagrees with both allegations. In this respect, it is important to review the recent history of the EPA's regulatory actions and litigation with respect to good neighbor obligations for both the 2008 and 2015 ozone NAAQS, and in particular, the substantial additional workload the Agency took on in the wake of the remand of the CSAPR Update in *Wisconsin.* In 2018, as the EPA issued the memoranda cited by commenters and planned to shift its focus to implementing the 2015 standards, it also issued the CSAPR Close-out, which made an analytical finding that there were no further obligations for 21 states for the 2008 standards following the CSAPR Update. 83 FR 65878 (Dec. 21, 2018). However, contrary to the EPA's understanding that it had fully addressed good neighbor obligations for the 2008 ozone NAAQS, the D.C. Circuit's decisions in *Wisconsin* (remanding the CSAPR Update) and in *New York* (vacating the CSAPR Close-out), forced the Agency to quickly pivot back to addressing remaining obligations under the 2008 standards. *Wisconsin* v. *EPA,* 938 F.3d 303 (D.C. Cir. 2019); *New York* v. *EPA,* 781 F. App'x. 4 (D.C. Cir. 2019). The EPA was subject to renewed deadline suit litigation under CAA section 304, which led to a March 15, 2021, deadline to take final action on several states whose FIPs had been remanded and were incomplete in the wake of the CSAPR Close-out vacatur. *New Jersey* v. *Wheeler,* 475 F.Supp.3d 308 (S.D.N.Y. 2020). Throughout 2020 and 2021, the EPA was therefore focused on an unexpected rulemaking obligation to complete good neighbor requirements as to the states with remanded CSAPR Update FIPs. This led to the EPA proposing and then issuing an economically significant, major rule assessing additional EGU emissions reduction obligations as well as presenting updated air quality modeling analysis using novel techniques and presenting information on a host of non-EGU industrial sources for the first time, *i.e.,* the Revised CSAPR Update, 86 FR 23054 (April 30, 2021). That rule is now currently subject to judicial review in the D.C. Circuit, *Midwest Ozone Group* v. *EPA,* No. 21–1146 (D.C. Cir. argued Sept. 28, 2022).[285] The EPA has also been in the process of reviewing and acting upon many states' good neighbor SIPs where the available information indicates that an approval of the state's submission was appropriate.[286]

Finally, the Agency needed time to review and evaluate the SIP submissions in a coordinated fashion to act on all the states' submissions in a consistent manner. As the EPA explained in the proposed disapproval action, consistency in defining CAA obligations is critically important in the context of addressing a regional-scale pollutant like ozone. *See, e.g.,* 87 FR 9807 n.48. Through coordinated development of the bases for how the Agency could act on the SIP submissions, while also evaluating the contours of a potential Federal plan to implement obligations where required, the EPA sequenced its deliberations and decision making to maximize efficient, consistent, and timely action, in recognition of the need to implement any necessary obligations ''as expeditiously as practicable.''[287] The downsides of commenters' policy preference in favor of giving states another opportunity to develop SIP submissions, or in first acting on each SIP submission before proposing a FIP, are that such a sequence of actions would have led to multiple years of additional delay in addressing good neighbor obligations. Even if such a choice was available to the Agency using the CAA section 110(k)(5) SIP call mechanism, it was entirely reasonable for the EPA to decline to use that mechanism in this instance. (EPA further addresses comments in support of a SIP call approach in the RTC document.)

In short, commenters' notion that the EPA was deliberately or intentionally deferring or delaying action on these SIP submissions to circumvent any required legal process or reach any specific result is simply incorrect. Commenters have not supplied any evidence to support the claim either that any legal process was circumvented or that the Agency's conduct was in bad faith. *See Biden* v. *Texas,* 142 S.Ct. 2528, 2546–47 (2022) (presumption of regularity attends agency action absent a ''strong showing of bad faith or improper behavior'') (citing *Citizens to Protect Overton Park* v. *Volpe,* 401 U.S. 302, 420 (1971); *SEC* v. *Chenery,* 318 U.S. 80, 87 (1943)).

4. Use of Updated Modeling

Comment: Comments allege that by relying on modeling not available at the time of SIP submission development, the EPA ''moved the goal post.'' Comments note the timeframes set out for action on SIPs, citing section 110 of the Act, and allege that by failing to act on SIP submissions in a timely manner and basing such actions on new modeling, the EPA imposes an arbitrary and capricious standard. Comments state that the EPA should not disapprove a SIP based on data not available to states during development of the SIP submissions or to the EPA during the period statutorily allotted for the EPA to take final action on SIP submissions.

EPA Response: In response to comments' claims that the EPA has inappropriately changed states' obligations for interstate transport by relying on updated modeling not available to states at the time they prepared their SIP submissions, the EPA disagrees. As an initial matter, the EPA disagrees with comment's claiming that the agency expected state air agencies to develop a SIP submission based on

[285] During this time, the EPA also fulfilled its obligations to act on several petitions brought by downwind states under section 126(b) of the CAA. These actions culminated in litigation and ultimately adverse decisions in *Maryland* and *New York* v. *EPA. Maryland v,* 958 F.3d; *New York* v. *EPA,* 964 F.3d 1214, 2020 WL 3967838 (D.C. Cir. 2020). Further review and action on these remands remains pending before the agency.

[287] CAA section 181(a); *Wisconsin,* 938 F.3d at 313–14 (citing *North Carolina,* 531 F.3d at 911–12).

some unknown future data. The EPA recognizes that states generally developed their SIP submissions with the best available information at the time of their development. As stated in the proposals, the EPA did not evaluate states' SIP submissions based solely on the 2016v2 emissions platform (or the 2016v3 platform, which incorporates comments generated during the public comment period on the proposed SIP actions and which supports these final SIP disapproval actions). We evaluated the SIP submissions based on the merits of the arguments put forward in each SIP submission, which included any analysis put forward by states to support their conclusions. Thus, we disagree with commenters who allege the Agency has ignored the information provided by the states in their submissions. Indeed, the record for this action reflects our extensive evaluation of states' air quality and contribution analyses. *See* generally Section IV, which summarizes our evaluation for each state.

We disagree with commenters who advocate that the EPA's evaluation of these submissions must be limited to the information available to states at the time they made their submissions, or information at the time of the deadline for the EPA to act on their submissions. It can hardly be the case that the EPA is prohibited from taking rulemaking action using the best information available to it at the time it takes such action. Nothing in the CAA suggests that the Agency must deviate from that general principle when acting on SIP submissions. While CAA section 110(k)(2) specifies a time period in which the Administrator is to act on a state submission, neither this provision nor any other provision of the CAA specifies that the remedy for the EPA's failure to meet a statutory deadline is to arrest or freeze the information the EPA may consider to what was available at the time of a SIP submission deadline under CAA section 110. Indeed, in the interstate transport context, this would lead to an anomalous result. For example, the D.C. Circuit rejected an argument made by Delaware against the CSAPR Update air quality analysis that the EPA was limited to reviewing air quality conditions in 2011 (rather than 2017) at the time of the statutory deadline for SIP submittals. The court explained,

> Delaware's argument leans too heavily on the SIP submission deadline. SIP submission deadlines, unlike attainment deadlines, are ''procedural'' and therefore not ''central to the regulatory scheme.'' *Sierra Club,* 294 F.3d at 161. Nor can Delaware's argument be reconciled with the text of the Good Neighbor Provision, which prohibits upwind States from emitting in amounts ''which *will*'' contribute to downwind nonattainment. 42 U.S.C. 7410(a)(2)(D)(i) (emphasis added). Given the use of the future tense, it would be anomalous for EPA to subject upwind States to good neighbor obligations in 2017 by considering which downwind States were once in nonattainment in 2011.

Wisconsin, 903 F.3d at 322. By the same token, here, holding the EPA to a consideration only of what information states had available regarding the 2023 analytic year at the time of their SIP submissions or at the time of a deadline under CAA section 110, would likewise elevate the ''procedural'' deadlines of CAA section 110 above the substantive requirements of the CAA that are ''central to the regulatory scheme.'' Doing so here would force the Agency to act on these SIP submissions knowing that more recent refined, high quality, state-of-the-science modeling and monitoring data would produce a different result in our forward-looking analysis of 2023 than the information available in 2018. Nothing in the CAA dictates that the EPA must be forced into making substantive errors in its good neighbor analysis on this basis.

We relied on CAMx Version 7.10 and the 2016v2 emissions platform to make updated determinations regarding which receptors would likely exist in 2023 and which states are projected to contribute above the contribution threshold to those receptors. As explained in the preamble of the EPA's proposed actions and further detailed in the document titled ''Air Quality Modeling TSD: 2015 Ozone National Ambient Air Quality Standards Proposed Interstate Transport Air Plan Disapproval'' and 2016v2 Emissions Inventory TSD, both available in Docket ID no. EPA–HQ–OAR–2021–0663, the 2016v2 modeling built off previous modeling iterations used to support the EPA's action on interstate transport obligations. The EPA continuously refines its modeling to ensure the results are as indicative as possible of air quality in future years. This includes adjusting our modeling platform and updating our emissions inventories to reflect current information.

Additionally, we disagree with comments claiming that the 2016v2 modeling results were sprung upon the states with the publication of the proposed disapprovals. The EPA has been publishing a series of data and modeling releases beginning as early as the publication of the 2016v1 modeling with the proposed Revised CSAPR Update in November of 2020, which could have been used to track how the EPA's modeling updates were potentially affecting the list of possible receptors and linkages for the 2015 ozone NAAQS in the 2023 analytic year. The 2016-based meteorology and boundary conditions used in the modeling have been available through the 2016v1 platform, which was used for the Revised CSAPR Update (proposed in November of 2020, 85 FR 68964). The updated emissions inventory files used in the current modeling were publicly released September 21, 2021, for stakeholder feedback, and have been available on our website since that time.[288] The CAMx modeling software that the EPA used has likewise been publicly available for over a year. CAMx version 7.10 was released by the model developer, Ramboll, in December 2020. On January 19, 2022, we released on our website and notified a wide range of stakeholders of the availability of both the modeling results for 2023 and 2026 (including contribution data) along with many key underlying input files.[289]

By providing the 2016 meteorology and boundary conditions (used in the 2016v1 version) in fall of 2020, and by releasing updated emissions inventory information used in 2016v2 in September of 2021,[290] states and other interested parties had multiple opportunities prior to the proposed disapprovals in February of 2022 to consider how our modeling updates could affect their status for purposes of evaluating potential linkages for the 2015 ozone NAAQS. Further, by using the updated modeling results, the EPA is using the most current and technically appropriate information for this rulemaking. This modeling was not performed to ''move the goal posts'' for states but meant to provide updated emissions projections, such as additional emissions reductions for EGUs following promulgation of the Revised CSAPR Update for the 2008 ozone NAAQS, more recent information on plant closures and fuel switches, and sector trends, including non-EGU sectors. The construct of the 2016v2 emissions platform is described in the 2016v2 Emissions Modeling TSD contained in Docket ID No. EPA–HQ–OAR–2021–0663.

Finally, comments related to the timing of the EPA's action to disapprove these SIP submissions are addressed in Section V.A.1. The EPA notes the statute provides a separate remedy for agency action unlawfully delayed. In section 304 of the CAA, there is a

[288] *See https://www.epa.gov/air-emissions-modeling/2016v2-platform.*

[289] *See https://www.epa.gov/scram/photochemical-modeling-applications.*

[290] *https://www.epa.gov/air-emissions-modeling/2016v2-platform.*

process for filing suit against the EPA for its failure to comply with a non-discretionary statutory duty under the CAA. The appropriate remedy in such cases is an order to compel agency action, not a determination that the agency, by virtue of missing a deadline, has been deprived of or constrained in its authority to act. *See Oklahoma,* 723 F.3d at 1224 (''[W]hen 'there are less drastic remedies available for failure to meet a statutory deadline'—such as a motion to compel agency action—'courts should not assume that Congress intended the agency to lose its power to act.' The Court 'would be most reluctant to conclude that every failure of an agency to observe a procedural requirement voids subsequent agency action, especially when important public rights are at stake.''') (cleaned up) (quoting *Brock* v. *Pierce County,* 476 U.S. 253, 260 (1986)).

Comment: Comments state that it is inappropriate for the EPA to revise its emissions inventory and to conduct new air quality modeling without allowing an appropriate opportunity for stakeholder review and comment and that the EPA must allow public comment on any updated (*i.e.,* 2016v3) modeling prior to use by the EPA in a final action. Comments claim that the EPA must withdraw the proposed disapproval and provide states time to develop new SIP submissions based on the updated information.

EPA Response: The EPA has evaluated a wide range of technical information and critiques of its 2016v2 emissions inventory and modeling platform following a solicitation of public feedback as well the public comment period on this action (and the proposed FIP action) and has responded to those comments and incorporated updates into the version of the modeling being used in this final action (2016v3). *See* Section III, the Final Action AQM TSD, and Section 4 of the RTC document for further discussion.

The EPA's development of and reliance on newer modeling to confirm modeling used at the proposal stage is in no way improper and is simply another iteration of the EPA's longstanding scientific and technical work to improve our understanding of air quality issues and causes going back decades. Where the 2016v3 modeling produced a potentially different outcome for states from proposal, that is reflected in this action (*e.g.,* our deferral of final action on Tennessee and Wyoming's SIP submissions).

Comment: Comments allege that EPA's modeling results have been inconsistent, questioning the reliability of the results.

EPA Response: Although some commenters indicate that our modeling iterations have provided differing outcomes and are therefore unreliable, this is not what the overall record indicates. Rather, in general, although the specifics of states' linkages may change slightly, our modeling overall has provided consistent outcomes regarding which states are linked to downwind air quality problems. For example, the EPA's modeling shows that most states that were linked to one or more receptors using the 2011-based platform (*i.e.,* the March 2018 data release) are also linked to one or more receptors using the newer 2016-based platform. Because each platform uses different meteorology (*i.e.,* 2011 and 2016) it is not at all unexpected that an upwind state could be linked to different receptors using 2011 versus 2016 meteorology.

In addition, although a state may be linked to a different set of receptors, states are often linked to receptors in the same area that has a persistent air quality problem. These differing results regarding receptors and linkages can be affected by the varying meteorology from year to year, but this does not indicate that the modeling or the EPA or the state's methodology for identifying receptors or linkages is inherently unreliable. Rather, for many states these separate modeling runs all indicated: (i) that there would be receptors in areas that would struggle with nonattainment or maintenance in the future, and (ii) that the state was linked to some set of these receptors, even if the receptors and linkages differed from one another in their specifics (*e.g.,* a different set of receptors were identified to have nonattainment or maintenance problems, or a state was linked to different receptors in one modeling run versus another).

The EPA interprets this common result as indicative that a state's emissions have been substantial enough to generate linkages at Step 2 to varying sets of downwind receptors generated under varying assumptions and meteorological conditions, even if the precise set of linkages changed between modeling runs. Under these circumstances, we think it is appropriate to proceed to a Step 3 analysis to determine what portion of a particular state's emissions should be deemed ''significant.'' We also note that only four states included in the proposed disapprovals went from being unlinked to being linked between the 2011-based modeling provided in the March 2018 memorandum and the 2016v2-based modeling—Alabama, Minnesota, Nevada, and Tennessee.

5. Cooperative Federalism and the EPA's Authority

Comment: Many comments point to the concept of cooperative federalism as embodied in the CAA to make various arguments as to why the EPA cannot or should not be allowed to exercise its independent judgment in evaluating the arguments presented by the states in the SIP submissions, and some also argue that the EPA must approve each state's submission in deference to how states choose to interpret the CAA requirements they must meet.

EPA Response: The CAA establishes a framework for state-Federal partnership to implement the NAAQS based on cooperative federalism. Under the general model of cooperative federalism, the Federal Government establishes broad standards or goals, states are given the opportunity to determine how they wish to achieve those goals, and if states choose not to or fail to adequately implement programs to achieve those goals, a Federal agency is empowered to directly regulate to achieve the necessary ends. Under the CAA, once the EPA establishes or revises a NAAQS, states have the obligation and opportunity in the first instance to develop an implementation plan under CAA section 110 and the EPA will approve SIP submissions under CAA section 110 that fully satisfy the requirements of the CAA. This sequence of steps is not in dispute.

The EPA does not, however, agree with the comments' characterization of the EPA's role in the state-Federal relationship as being ''secondary'' such that the EPA must defer to state choices heedless of the substantive objectives of the Act; such deference would be particularly inappropriate in the context of addressing interstate pollution. The EPA believes that the comments fundamentally misunderstand or inaccurately describe this action, as well as the '''division of responsibilities' between the states and the federal government'' they identify in CAA section 110 citing the *Train-Virginia* line of cases [291] and other cases.[292]

[291] *See Virginia* v. *EPA,* 108 F.3d 1397, 1407 (D.C. Cir. 1997) (*Virginia*) (quoting *Train* v. *Natural Resources Defense Council, Inc.*, 421 U.S. 60, 79 (1975) (*Train*)). The ''Train-Virginia line of cases'' are named for the U.S. Supreme Court case *Train,* 421 U.S. and to the D.C. Circuit case *Virginia,* 108 F.3d. The D.C. Circuit has described these cases as defining a ''federalism bar'' that generally recognizes states' ability to select emissions control measures in their SIPs so long as CAA requirements are met. *See, e.g., Michigan* v. *EPA,* 213 F.3d 663, 687 (D.C. Cir. 2000) (*Michigan*).

[292] *Union Elec. Co.* v. *EPA,* 427 U.S. 246 (1976), *Am. Elec. Power Co.* v. *Connecticut,* 565 U.S. 410 (2011), *Fla. Power & Light* v. *Costle,* 650 F.2d 579

Continued

Those cases, some of which pre-date the CAA amendments of 1990 resulting in the current Good Neighbor Provision,[293] stand only for the proposition that the EPA must approve state plans *if* they meet the applicable CAA requirements. But these cases say nothing about what those applicable requirements are. The EPA is charged under CAA section 110 with reviewing states' plans for compliance with the CAA and approving or disapproving them based on EPA's determinations. Thus, the EPA must ultimately determine whether state plans satisfy the requirements of the Act or not. Abundant case law reflects an understanding that the EPA must evaluate SIP submissions under the CAA section 110(k)(2) and (3).[294] If they are deficient, the EPA must so find, and become subject to the obligation to directly implement the relevant requirements through a Federal implementation plan under CAA section 110(c), unless EPA approves an applicable SIP first.[295]

The EPA responds in greater detail to these comments in the RTC document.

6. Availability of Guidance for SIP Submissions

Comment: Comments contend the EPA failed to issue guidance in a timely fashion by releasing its August 2018 memorandum 31 days prior to when SIPs addressing interstate ozone transport were due and issuing the October 2018 memorandum 18 days after those SIPs were due. Some comments additionally claim that it is unreasonable for the EPA to disapprove SIP submissions based on standards that were not defined, mandated, or required by official guidance.

EPA Response: Comments' contention is unsupported by the statute or applicable case law. Regarding the need for the EPA's guidance in addressing good neighbor obligations, in *EME Homer City,* the Supreme Court clearly held that ''nothing in the statute places the EPA under an obligation to provide specific metrics to States before they undertake to fulfill their good neighbor obligations.''[296]

Nonetheless, as comments point out, the EPA issued three ''memoranda'' in 2018 to provide some assistance to states in developing these SIP submissions. In acting on the SIP submissions in this action, the EPA is neither rescinding nor acting inconsistently with the memoranda—to the extent the memoranda constituted agency guidance (not all the information provided did constitute guidance), information or ideas in the memoranda had not at that time been superseded by case law developments, and the memoranda's air quality and contribution data had not at that time been overtaken by updated modeling and other updated air quality information. While comments specific to each of those memoranda are addressed elsewhere in this record, we note in brief that each memorandum made clear that the EPA's action on SIP submissions would be through a separate notice-and-comment rulemaking process and that SIP submissions seeking to rely on or take advantage of any information or concepts in these memoranda would be carefully reviewed against the relevant legal requirements and technical information available to the EPA at the time it would take such rulemaking action.

B. Application of the 4-Step Interstate Transport Framework

1. Analytic Year

Comment: One comment asserted that 2023 is not an appropriate analytical year because, according to the commenter, the EPA and at least some downwind states have not in fact implemented mandatory emissions control requirements associated with their nonattainment areas, and *North Carolina* and *Wisconsin* require that upwind and downwind state obligations must be implemented ''on par.'' The comment also characterizes the EPA's invocation of *Maryland* as an inappropriate shifting of regulatory burden to upwind states.

EPA Response: This is an incorrect interpretation of the D.C. Circuit's holdings in *North Carolina, Wisconsin,* and *Maryland,* which held that the EPA and the states must align good neighbor obligations to the extent possible with the downwind areas' attainment dates. These are set by the statute and remain fixed regardless of whether downwind areas are delayed in implementing their own obligations. It would be unworkable to expect that upwind states' obligations could be perfectly aligned with each downwind area's actual timetable for implementing the relevant emissions controls, and no court has held that this is the EPA's or the states' obligation under the good neighbor provision. Further, this ignores the fact that upwind states must also address their interference with maintenance of the NAAQS, as well as the *Maryland* court's holding that good neighbor obligations should be addressed by the Marginal area attainment date for ozone under subpart 2 of part D of title I of the CAA. Both circumstances may involve situations in which the home state for an identified downwind receptor does not have a specific obligation to plan for and implement specific emissions controls while an upwind state may nonetheless be found to have good neighbor obligations. But, as the *Maryland* court recognized, the absence of specific enumerated requirements does not mean the downwind state does not have a statutorily binding obligation subject to burdensome regulatory consequences: ''Delaware must achieve attainment 'as expeditiously as practicable,''' and ''an upgrade from a marginal to a moderate nonattainment area carries significant consequences . . . .'' *Maryland,* 958 F.3d at 1204.

Further, where any downwind-state delays are unreasonable or violate statutory timeframes, the CAA provides recourse to compel the completion of such duties in CAA section 304, not to defer the elimination of significant contribution and thereby expose the public in downwind areas to the elevated pollution levels caused in part by upwind states' pollution. Regardless, in this action, 2023 aligns with the Moderate area attainment date in 2024, and all of the downwind nonattainment areas corresponding to receptor locations identified at Step 1 in this action are already classified as being in Moderate nonattainment or have been reclassified to Moderate and the relevant states face obligations to submit

(5th Cir. 1981), *Bethlehem Steel Corp.* v. *Gorsuch,* 742 F.2d 1028 (7th Cir. 1984), *Concerned Citizens of Bridesburg* v. *EPA,* 836 F.2d 777 (3d Cir. 1987), *North Carolina,* 531 F.3d 896, *Luminant,* 675 F.3d 917 (5th. Cir. 2012), *Luminant Co. LLC* v. *EPA,* 714 F.3d 841 (5th. Cir. 2013), *North Dakota* v. *EPA,* 730 F.3d 750 (8th. Cir. 2013), *EME Homer City II,* 795 F.3d 118 (D.C. Cir. 2015), and *Texas* v. *USEPA,* 829 F.3d 405 (5th. Cir. 2016).

[293] The 1970 version of the Act required SIPs to include ''adequate provisions for intergovernmental cooperation'' concerning interstate air pollution. CAA section 110(a)(2)(E), 84 Stat. 1681, 42 U.S.C. 1857c–5(a)(2)(E). In 1977, Congress amended the Good Neighbor Provision to direct States to submit SIP submissions that included provisions ''adequate'' to ''prohibi[t] any stationary source within the State from emitting any air pollutant in amounts which will . . . prevent attainment or maintenance [of air quality standards] by any other State.'' CAA section 108(a)(4), 91 Stat. 693, 42 U.S.C. 7410(a)(2)(E) (1976 ed., Supp. II). Congress again amended the Good Neighbor Provision in 1990 to its current form.

[294] *See, e.g., Virginia,* 108 F.3d at 1406. *See also, e.g., Westar Energy* v. *EPA,* 608 Fed. App'x 1, 3 (D.C. Cir. 2015) (''EPA acted *well within the bounds* of its delegated authority when it disapproved of Kansas's proposed [good neighbor] SIP.'') (emphasis added); *Oklahoma,* 723 F.3d at 1209 (upholding the EPA's disapproval of ''best available retrofit technology'' (BART) SIP, noting BART ''does not differ from other parts of the CAA—states have the ability to create SIPs, but they are subject to EPA review'').

[295] *EME Homer City Generation,* 572 U.S. at 508–510.

[296] *EME Homer City,* 572 U.S. at 510.

SIP submissions and implement reasonably available control technologies (RACT) by January 1, 2023. *See* 87 FR 60897, 60899 (October 7, 2022). The EPA further responds to this comment in the RTC document.

2. Attachment A to the March 2018 Memorandum

Comment: Comments state that states conducted their analyses based on the flexibilities listed in Attachment A of the March 2018 Memorandum. Comments cite the part of the memorandum where the EPA notes that ''in developing their own rules, states have flexibility to follow the familiar four-step transport framework (using [the] EPA's analytical approach or somewhat different analytical approaches within these steps) or alternative frameworks, so long as their chosen approach has adequate technical justification and is consistent with the requirements of the CAA.'' Comments state that the EPA's disapproval of SIP submissions that took advantage of the flexibilities is arbitrary and capricious because the EPA has changed, without communication, its consideration of what is deemed to be the ''necessary provisions'' required for an approvable SIP submission too late in the SIP submission process and because, in disapproving these SIPs, the EPA is applying a consistent set of policy judgments across all states.

EPA Response: Comments mistakenly view Attachment A to the March 2018 memorandum releasing modeling results as constituting agency guidance. The EPA further disagrees with commenters' characterization of the EPA's stance regarding the ''flexibilities'' listed (without analysis) in Attachment A. Attachment A to the March 2018 memorandum identified a ''Preliminary List of Potential Flexibilities'' that could potentially inform SIP development.[297] However, the EPA made clear in that attachment that the list of ideas were not suggestions endorsed by the Agency but rather ''comments provided in various forums'' from outside parties on which the EPA sought ''feedback from interested stakeholders.'' [298] Further, Attachment A stated, ''EPA is not at this time making any determination that the ideas discussed later are consistent with the requirements of the CAA, nor are we specifically recommending that states use these approaches.'' [299] Attachment A to the March 2018 memorandum, therefore, does not constitute agency guidance, but was intended to generate further discussion around potential approaches to addressing ozone transport among interested stakeholders. The EPA emphasized in this memorandum that any such alternative approaches must be technically justified and appropriate in light of the facts and circumstances of each particular state's submittal.[300] As stated in the proposed SIP disapprovals,[301] the March 2018 memorandum provided that, ''While the information in this memorandum and the associated air quality analysis data could be used to inform the development of these SIPs, the information is not a final determination regarding states' obligations under the good neighbor provision.'' [302] In this final SIP disapproval action, the EPA again affirms that certain concepts included in Attachment A to the March 2018 memorandum require unique consideration, and these ideas do not constitute agency guidance with respect to transport obligations for the 2015 ozone NAAQS.

In response to comments' claims that since the time transport SIP submissions were submitted to the EPA for review, the EPA has changed, without communication, its consideration of what is deemed to be the ''necessary provisions'' required for an approvable SIP submission, the EPA disagrees. As comments note, and as stated in the proposed disapproval notifications, the EPA recognizes that states have discretion to develop their own SIP transport submissions and agrees that states are not bound to using the 4-step interstate transport framework the EPA has historically used. However, states must then provide sufficient justification and reasoning to support their analytical conclusions and emissions control strategies. *See, e.g.,* 87 FR 9798, 9801. In the SIP submissions being disapproved in this action, no state provided any enforceable emissions control strategies for approval into their SIP. The EPA has evaluated the merits of each state's arguments as to why no additional emissions reduction requirements are needed to satisfy their obligations under CAA section 110(a)(2)(D)(i)(I) for the more protective 2015 ozone NAAQS. While the EPA used its own 4-step interstate transport framework as a guide for its review to ensure a consistent and equitable evaluation of each states' submissions, the EPA has also considered states' individual arguments without predetermining the EPA's conclusions about the state's transport obligations.

It was never the Agency's intent in sharing Attachment A that states would invoke one or more of the potential ''flexibilities'' that outside parties advocated for as a basis for concluding that no additional emissions controls were necessary to address interstate transport for the more protective 2015 ozone NAAQS without proper justification. Nothing in Attachment A suggested that was the Agency's intended objective. Indeed, where certain approaches identified in Attachment A might have produced analytical conclusions requiring upwind states to reduce their emissions, no state invoking Attachment A followed through with implementing those controls. We observe this dynamic at work in Kentucky's submission, because Kentucky appended comments from the Midwest Ozone Group to its submission that demonstrated that applying a ''weighted'' approach to allocating upwind-state responsibility at Step 3 would have resulted in an emissions control obligation on Kentucky's sources, yet the State offered no explanation in its submittal why it was not adopting that approach or even what its views on that approach were. *See* 87 FR 9515. As another example, Michigan cited Attachment A to the March 2018 in developing a methodology for calculating significant contribution under which Michigan would have been responsible for eliminating up to 0.12 ppb of contribution to downwind receptors; however, the State suggested that uncertainty caused by modeling ''noise'' was too great to either require emissions reductions or demonstrate that Michigan had any linkages to receptors at all. *See* 87 FR 9860–9861. However, this explanation did not, as an analytical matter, demonstrate a level of scientific uncertainty which might allow for ignoring the results,[303]

[297] March 2018 memorandum, Attachment A.

[298] *Id.*

[299] *Id.*

[300] March 2018 memorandum.

[301] E.g., 87 FR 9487.

[302] *See* Information on the Interstate Transport State Implementation Plan Submissions for the 2015 Ozone National Ambient Air Quality Standards under Clean Air Act Section 110(a)(2)(D)(i)(I), March 27, 2018, available in docket EPA–HQ–OAR–2021–0663 or at *https://www.epa.gov/interstate-air-pollution-transport/interstate-air-pollution-transport-memos-and-notices.*

[303] Scientific uncertainty may only be invoked to avoid comporting with the requirements of the CAA when ''the scientific uncertainty is so profound that it precludes . . . reasoned judgment'' *Massachusetts* v. *EPA,* 127 S.Ct. 1438 (2007). *See Wisconsin,* 938 F.3d at 318–19 (''Scientific uncertainty, however, does not excuse EPA's failure to align the deadline for eliminating upwind States' significant contributions with the deadline for downwind attainment of the NAAQS.''). *See also EME Homer City,* 795 F.3d at 135–36 (''We will not invalidate EPA's predictions solely because there might be discrepancies between those predictions

Continued

particularly when the Agency has implemented good neighbor requirements at levels of ''significant contribution'' comparable to or even less than 0.12 ppb. *See Wisconsin,* 938 F.3d at 322–23 (rejecting Wisconsin's argument that it should not face good neighbor obligations for the 2008 ozone NAAQS on the basis that its emission reductions would only improve a downwind receptor by two ten-thousandths of a part per billion).

The EPA continues to neither endorse the ''flexibilities'' in Attachment A, nor stakes a position that states are precluded from relying on these concepts in the development of their good neighbor SIP submissions, assuming they could be adequately justified both technically and legally. This has been demonstrated through the EPA's extensive evaluation of the merits of each states' SIP submissions, including their attempted use of flexibilities and derivatives of the EPA's historically applied 4-step interstate transport framework.[304]

3. Step 1: October 2018 Memorandum

Comments: Comments claimed that the EPA is not honoring its October 2018 memorandum, which they claim would allow for certain monitoring sites identified as maintenance-only receptors in the EPA's methodology to be excluded as receptors based on historical data trends. They assert that the EPA is inappropriately disapproving SIP submissions where the state sufficiently demonstrated certain monitoring sites should not be considered to have a maintenance problem in 2023.

EPA Response: The October 2018 memorandum recognized that states may be able to demonstrate in their SIPs that conditions exist that would justify treating a monitoring site as not being a maintenance receptor despite results from our modeling methodology identifying it as such a receptor. The EPA explained that this demonstration could be appropriate under two circumstances: (1) the site currently has ''clean data'' indicating attainment of the 2015 ozone NAAQS based on measured air quality concentrations, or (2) the state believes there is a technical reason to justify using a design value from the baseline period that is lower than the maximum design value based on monitored data during the same baseline period. To justify such an approach, the EPA anticipated that any such showing would be based on an analytical demonstration that: (1) Meteorological conditions in the area of the monitoring site were conducive to ozone formation during the period of clean data or during the alternative base period design value used for projections; (2) ozone concentrations have been trending downward at the site since 2011 (and ozone precursor emissions of NO_X and VOC have also decreased); and (3) emissions are expected to continue to decline in the upwind and downwind states out to the attainment date of the receptor. EPA evaluated state's analyses and found no state successfully applied these criteria to justify the use of one of these alternative approaches. The air quality data and projections in Section III indicate that trends in historic measured data do not necessarily support adopting a less stringent approach for identifying maintenance receptors for purposes of the 2015 ozone NAAQS. In fact, as explained in Section III, the EPA has found in its analysis for this final action that, in general, recent measured data from regulatory ambient air quality ozone monitoring sites suggest a number of receptors with elevated ozone levels will persist in 2023 even though our traditional methodology at Step 1 did not identify these monitoring sites as receptors in 2023. Thus, the EPA is not acting inconsistently with that memorandum—the factual conditions that would need to exist for the suggested approaches of that memorandum to be applicable have not been demonstrated as being applicable or appropriate based on the relevant data.

We further respond to comments related to the identification of receptors at Step 1 the RTC document.

4. Step 2: Technical Merits of a 1 Percent of the NAAQS Contribution Threshold

Comment: Several comments contend that for technical reasons, the 0.70 ppb threshold is inappropriate for determining whether a state is linked to a downwind receptor at Step 2 of the 4-step interstate transport framework. Comments state that the degree to which errors exist in modeling ozone concentrations and contributions make it inappropriate for a threshold as low as 0.70 ppb to be used. Some comments further state that the 0.70 ppb threshold is inappropriate because the concentration threshold is lower than what monitoring devices are capable of detecting. Comments reference the reported precision of Federal reference monitors for ozone and the rounding requirements found in 40 CFR part 50, appendix U, Interpretation of the Primary and Secondary National Ambient Air Quality Standards for Ozone, for support. Comments note that the 1 percent contribution threshold of 0.70 ppb is lower than the manufacturer's reported precision of Federal reference monitors for ozone and that the requirements found in appendix U truncates monitor values of 0.70 ppb to 0 ppb.

EPA Response: The EPA disagrees that a 1 percent of the NAAQS contribution threshold at Step 2 is ''inappropriate'' for the 2015 ozone NAAQS due to modeling biases and errors. The explanation for how the 1 percent contribution threshold was originally derived is available in the 2011 CSAPR rulemaking. *See* 76 FR 48208, 48236–38 (Aug. 8, 2011). The EPA has effectively applied a 1 percent of the NAAQS threshold to identify linked upwind states in three prior FIP rulemakings and numerous state-specific actions. The D.C. Circuit has declined to establish bright line criteria for model performance. In upholding the EPA's approach to evaluating interstate transport in CSAPR, the D.C. Circuit held that it would not ''invalidate EPA's predictions solely because there might be discrepancies between those predictions and the real world. That possibility is inherent in the enterprise of prediction.'' *EME Homer City II,* 795 F.3d at 135. The court continued to note that ''the fact that a 'model does not fit every application perfectly is no criticism; a model is meant to simplify reality in order to make it tractable.' '' *Id.* at 135–36 (quoting *Chemical Manufacturers Association* v. *EPA,* 28 F.3d 1259, 1264 (DC Cir. 1994). *See also Sierra Club* v. *EPA,* 939 F.3d 649, 686–87 (5th Cir. 2019) (upholding the EPA's modeling in the face of complaints regarding an alleged ''margin of error,'' noting challengers face a ''considerable burden'' in overcoming a ''presumption of regularity'' afforded ''the EPA's choice of analytical methodology'') (citing *BCCA Appeal Grp.* v. *EPA,* 355 F.3d 817, 832 (5th Cir. 2003)).

Furthermore, it is not appropriate to compare the bias/error involved in the estimation of total ozone to the potential error in the estimation of the subset of ozone that is contributed by a single state.[305] For example, on a specific day

and the real world. That possibility is inherent in the enterprise of prediction.'').

[304] Nor in the course of this evaluation has the EPA uniformly ruled out the concepts in Attachment A. For example, we noted at proposal that California's identification of a flexibility in Attachment A related to excluding certain air quality data associated with atypical events may be generally consistent with the EPA's modeling guidance, but this does not affect the ultimate determination that California's SIP is not approvable. *See* 87 FR 31454.

[305] See, *e.g.,* 87 FR 9798 at 9816.

the modeled versus monitored ozone value may differ by 2 ppb but that is a relatively small percentage of the total modeled ozone, which for a receptor of interest would be on the order of 70 ppb. It would be unrealistic to assign all of the 2 ppb discrepancy in the earlier example to the estimated impact from a single state because the 2 ppb error would be the combination of the error from all sources of ozone that contribute to the total, including estimated impacts from other states, the home state of the receptor, and natural background emissions.

To address comments that compare the 0.70 ppb threshold to the Federal reference monitors for ozone and the rounding requirements found in 40 CFR part 50, appendix U, the EPA notes that the comment is mistaken in applying criteria related to the precision of monitoring data to the modeling methodology by which we project contributions when quantifying and evaluating interstate transport at Step 2. Indeed, contributions by source or state cannot be derived from the total ambient concentration of ozone at a monitor at all but must be apportioned through modeling. Under our longstanding methodology for doing so, the contribution values identified from upwind states are based on a robust assessment of the average impact of each upwind state's ozone-precursor emissions over a range of scenarios, as explained in the Final Action AQM TSD. This analysis is in no way connected with or dependent on monitoring instruments' precision of measurement. *See EME Homer City II,* 795 F.3d 118, 135–36 ('''[A] model is meant to simplify reality in order to make it tractable.''').

5. Step 2: Justification of a 1 Percent of the NAAQS Contribution Threshold

Comment: Comments contend that the EPA has not provided enough basis for reliance on the 0.70 ppb threshold, claiming that its use is therefore arbitrary and capricious.

EPA Response: The EPA is finalizing its proposed approach of consistently using a 1 percent of the NAAQS contribution threshold at Step 2. This approach ensures both national consistency across all states and consistency and continuity with our prior interstate transport actions for other NAAQS. Comments have not established that this approach is either unlawful or arbitrary and capricious.

The 1 percent threshold is consistent with the Step 2 approach that the EPA applied in CSAPR for the 1997 ozone NAAQS, which has subsequently been applied in the CSAPR Update and revised CSAPR Update when evaluating interstate transport obligations for the 2008 ozone NAAQS. The EPA continues to find 1 percent to be an appropriate threshold. For ozone, as the EPA found in the CAIR, CSAPR, and CSAPR Update, a portion of the nonattainment and maintenance problems in the U.S. results from the combined impact of relatively small contributions from many upwind states, along with contributions from in-state sources and other sources. The EPA's analysis shows that much of the ozone transport problem being analyzed for purposes of evaluating 2015 ozone NAAQS SIP obligations is still the result of the collective impacts of contributions from many upwind states. Therefore, application of a consistent contribution threshold is necessary to identify those upwind states that should have responsibility for addressing their contribution to the downwind nonattainment and maintenance problems to which they collectively contribute. Where a great number of geographically dispersed emissions sources contribute to a downwind air quality problem, which is the case for ozone, EPA believes that, in the context of CAA section 110(a)(2)(D)(i)(I), a state-level threshold of 1 percent of the NAAQS is a reasonably small enough value to identify only the greater-than-de minimis contributers yet is not so large that it unfairly focuses attention for further action only on the largest single or few upwind contributers. Continuing to use 1 percent of the NAAQS as the screening metric to evaluate collective contribution from many upwind states also allows the EPA (and states) to apply a consistent framework to evaluate interstate emissions transport under the interstate transport provision from one NAAQS to the next. *See* 81 FR 74504, 74518. *See also* 86 FR 23054, 23085 (reviewing and explaining rationale from CSAPR, 76 FR 48208, 48236–38, for selection of 1 percent threshold).

Further, the EPA notes that the role of the Step 2 threshold is limited and just one step in the 4-Step interstate transport framework. It serves to screen in states for further evaluation of emissions control opportunities applying a multifactor analysis at Step 3. Thus, as the Supreme Court has recognized, the contribution threshold essentially functions to exclude states with ''de minimis'' impacts. *EME Homer City,* 572 U.S. at 500.

Comment: Commenters contend that the EPA cannot use the 1 percent threshold as a determination for significance.

EPA Response: To clarify, the EPA does not use the 1 percent of the NAAQS threshold as the definition of ''significance.'' Rather, where a state's contribution equals or exceeds the 1 percent of the NAAQS threshold, the EPA expects states to further evaluate their emissions to determine whether their emissions constitute significant contribution or interference with maintenance. The contribution threshold is a screening threshold to identify states which may be ''contributing'' to an out of state receptor. The EPA has maintained this interpretation of the relevant statutory language across many rulemakings, though commenters continue to confuse the Step 2 threshold with a determination of ''significance,'' which it is not. *See EME Homer City,* 572 U.S. at 500–502 (explaining the difference between the ''screening'' analysis at Steps 1 and 2 whereby the EPA ''excluded as de minimis any upwind State that contributed less than one percent of the . . . NAAQS'' and the ''control'' analysis at Step 3 whereby the EPA determined ''cost thresholds'' to define significance).

Further, the EPA's air quality and contribution modeling for ozone transport is based on application of the model in a relative sense rather than relying upon absolute model predictions. All models have limitations resulting from uncertainties in inputs and scientific formulation. To minimize the effects of these uncertainties, the modeling is anchored to base period measured data in the EPA's guidance approach for projecting design values. Notably, the EPA also uses our source apportionment modeling in a relative sense when calculating the average contribution metric (used to identify linkages). In this method the magnitude of the contribution metric is tied to the magnitude of the projected average design value which is tied to the base period average measured design value. The EPA's guidance has recommended against applying bright-line criteria for judging whether statistical measures of model performance constitute acceptable or unacceptable model performance.

The Agency continues to find that this method using the CAMx model to evaluate contributions from upwind states to downwind areas is reliable. The agency has used CAMx routinely in previous notice and comment transport rulemakings to evaluate contributions relative to the 1 percent threshold for both ozone and $PM_{2.5}$. In fact, in the original CSAPR, the EPA found that ''[t]here was wide support from commenters for the use of CAMx as an appropriate, state-of-the science air quality tool for use in the [Cross-State Air Pollution] Rule. There were no comments that suggested that the EPA should use an alternative model for quantifying interstate transport.'' 76 FR 48229 (August 8, 2011). In this action, the EPA has taken a number of steps based on comments and new information to ensure to the greatest extent the accuracy and reliability of its modeling projections at Step 1 and 2, as discussed elsewhere in this document.

6. Step 2: Prevention of Significant Deterioration Significant Impact Levels

Comment: Several comments insist that when identifying an appropriate linkage threshold at Step 2 of the 4-step framework, the EPA should consider or rely on the 1 ppb significant impact level (SIL) for ozone used as part of the prevention of significant deterioration PSD permitting process. Comments reference the EPA's April 17, 2018, guidance memorandum, ''Significant Impact Levels for Ozone and Fine Particles in the Prevention of Significant Deterioration Permitting Program'' (SIL guidance), as well as the EPA's March 2018 memorandum's Attachment A flexibilities to lend support to their opinion that the 1 ppb SIL should also be used to determine linkages at Step 2.

EPA Response: The EPA's SIL guidance relates to a different provision of the Clean Air Act regarding implementation of the prevention of significant deterioration (PSD) permitting program. This program applies in areas that have been designated attainment of the NAAQS and is intended to ensure that such areas remain in attainment even if emissions were to increase as a result of new sources or major modifications to existing sources located in those areas. This purpose is different than the purpose of the good neighbor provision, which is to assist downwind areas (in some cases hundreds or thousands of miles away) in resolving ongoing nonattainment of the NAAQS or difficulty maintaining the NAAQS through eliminating the emissions from other states that are significantly contributing to those problems. In addition, as discussed earlier, the purpose of the Step 2 threshold within the EPA's interstate transport framework for ozone is to broadly sweep in all states contributing to identified receptors above a de minimis level in recognition of the collective-contribution problem associated with regional-scale ozone transport. The threshold used in the context of PSD SIL serves an entirely different purpose, and so it does not follow that they should be made equivalent. Further, comments incorrectly associate the EPA's Step 2 contribution threshold with the identification of ''significant'' emissions (which does not occur until Step 3), and so it is not the case that the EPA is interpreting the same term differently.

The EPA has previously explained this distinction between the good neighbor framework and PSD SILs. *See* 70 FR 25162, 25190–25191 (May 12, 2005); 76 FR 48208, 48237 (August 8, 2011). Importantly, the implication of the PSD SIL threshold is not that single-source contribution below this level indicates the absence of a contribution or that no emissions control requirements are warranted. Rather, the PSD SIL threshold addresses whether further, more comprehensive, multi-source review or analysis of air quality impacts are required of the source to support a demonstration that it meets the criteria for a permit. A source with estimated impacts below the PSD SIL may use this to demonstrate that it will not cause or contribute (as those terms are used within the PSD program) to a violation of an ambient air quality standard, but is still subject to meeting applicable control requirements, including best available control technology, designed to moderate the source's impact on air quality.

Moreover, other aspects of the technical methodology in the SIL guidance compared to the good neighbor framework make a direct comparison between these two values misleading. For instance, in PSD permit modeling using a single year of meteorology the maximum single-day 8-hour contribution is evaluated with respect to the SIL. The purpose of the contribution threshold at Step 2 of the 4-step good neighbor framework is to determine whether the average contribution from a collection of sources in a state is small enough not to warrant any additional control for the purpose of mitigating interstate transport, even if that control were highly cost effective. Using a 1 percent of the NAAQS threshold is more appropriate for evaluating multi-day average contributions from upwind states than a 1 ppb threshold applied for a single day, since that lower value of 1 percent of the NAAQS will capture variations in contribution. If EPA were to use a single day reflecting the maximum amount of contribution from an upwind state to determine whether a linkage exists at Step 2, comments' arguments for use of the PSD SIL might have more force. However, that would likely cause more states to become linked, not less. And in any case, consistent with the method in our modeling guidance for projecting future attainment/nonattainment, the good neighbor methodology of using multiple days provides a more robust approach to establishing that a linkage exists at the state level than relying on a single day of data.

7. Step 2: August 2018 Memorandum

Comment: Comments assert that in the August 2018 memorandum the EPA committed itself to approving SIP submissions from states with contributions below 1 ppb, and so now the EPA should or must approve the good neighbor SIP submission from any state with a contribution below 1 ppb, either based on modeling available at the time of the state's SIP submission or at any time.

EPA Response: These comments mischaracterize the content and the EPA's application of August 2018 memorandum. Further, the EPA disputes that the EPA misled states or that the EPA has not appropriately reviewed SIP submissions from states that attempted to rely on an alternative contribution threshold at Step 2.

Specifically, the EPA's August 2018 memorandum provided an analysis regarding ''the degree to which certain air quality threshold amounts capture the collective amount of upwind contribution from upwind states.'' [306] It interpreted ''that information to make recommendations about what thresholds *may* be appropriate for use in'' SIP submissions (emphasis added).[307] Specifically, the August 2018 memorandum said, ''Because the amount of upwind collective contribution capture with the 1 percent and the 1 ppb thresholds is generally comparable, overall, we believe it *may* be reasonable and appropriate for states to use a 1 ppb contribution threshold, as an alternative to a 1 percent threshold, at Step 2 of the 4-step framework in developing their SIP revisions addressing the good neighbor provision for the 2015 ozone NAAQS.'' (emphasis added).[308] Thus, the text of the August 2018 memorandum does not guarantee that any state with a contribution below 1 ppb has an automatically approvable good neighbor SIP. In fact, the August 2018 memorandum indicated that ''[f]ollowing these recommendations does not ensure that EPA will approve a SIP revision in all instances where the recommendations are followed, as the guidance may not apply to the facts and circumstances underlying a particular SIP. Final decisions by the EPA to approve a particular SIP revision will

[306] August 2018 memorandum, page 1.

[307] August 2018 memorandum, page 1.

[308] August 2018 memorandum, page 4.

only be made based on the requirements of the statute and will only be made following an air agency's final submission of the SIP revision to the EPA, and after appropriate notice and opportunity for public review and comment.'' [309] The August 2018 memorandum also stated, ''EPA and air agencies should consider whether the recommendations in this guidance are appropriate for each situation.'' [310] The EPA's assessment of every SIP submission that invoked the August 2018 memorandum considered the particular arguments raised by the state.[311]

Comment: Some comments allege that the EPA representatives led the states to believe that their SIP submission would be approved on the basis of a 1 ppb contribution threshold. The comments further claim that the EPA has now since reversed course on its August 2018 memorandum and imposed new requirements on states that were not included in the EPA's guidance. One comment suggested EPA switched position without explanation from the August 2018 guidance to its proposed disapprovals, which it viewed as unlawful under *FCC* v. *Fox TV Stations, Inc.,* 556 U.S. 502 (2009).

EPA Response: As an initial matter, we note that the salience of these comments is limited to only a handful of states. The August 2018 memorandum made clear that the Agency had substantial doubts that any threshold greater than 1 ppb (such as 2 ppb) would be acceptable, and the Agency is affirming that a threshold higher than 1 ppb would not be justified under any circumstance for purposes of this action. No comment provided a credible basis for using a threshold even higher than 1 ppb. So this issue is primarily limited to the difference between a 0.70 ppb threshold and a 1.0 ppb threshold. Therefore, we note that this issue is only relevant to a small number of states whose only contributions to any receptor are above 1 percent of the NAAQS but lower than 1 ppb. Under the 2016v3 modeling of 2023 being used in this final action, those states with contributions that fall between 0.70 ppb and 1 ppb included in this action are Alabama, Kentucky, and Minnesota.

The EPA disagrees with comments' claims that the Agency has reversed course on applying the August 2018 memorandum. In line with the memorandum, the EPA evaluated every justification put forward by every state covered by this SIP disapproval action that attempted to justify an alternative threshold under the August 2018 memorandum, which are Alabama,[312] Arkansas,[313] Illinois,[314] Indiana,[315] Kentucky,[316] Louisiana,[317] Michigan,[318] Mississippi,[319] Missouri,[320] and Oklahoma,[321] and Utah.[322] The EPA also addressed criticisms of the 1 percent of the NAAQS contribution threshold made by Ohio [323] and Nevada.[324] (The topic of the EPA's input during state's SIP-development processes is further discussed in the RTC document.)

For this reason, the EPA disagrees with comment that case law reviewing changes in agency positions as articulated in *FCC* v. *Fox TV Stations, Inc.,* is applicable to this action. The Agency has not imposed a requirement that states must use a 1 percent of the NAAQS threshold (which would reflect a change in position from the August 2018 memorandum). Rather, under the terms of the August 2018 memorandum, the Agency has found that Alabama, Arkansas, Illinois, Indiana, Kentucky, Louisiana, Michigan, Mississippi, Missouri, Nevada, Ohio, Oklahoma, and Utah have not made a sufficient showing that the use of an alternative contribution threshold is justified for those States. Even if it were found that the Agency's position had fundamentally changed between this rulemaking action and the August 2018 memorandum (which we do not concede to be the case), we do not believe that any state had a legitimate reliance interest that would be sufficient to overcome the countervailing public interest that is served in declining to approve a state's use of the 1 ppb threshold where the state did not have adequate technical justification. First, neither states nor the emissions sources located in those states have incurred any compliance costs based on the August 2018 memorandum. Second, it is not clear that any states invested much of their own public resources in developing state-specific arguments in support of a 1 ppb threshold. As the EPA observed at proposal, in nearly all submittals, the states did not provide the EPA with analysis specific to their state or the receptors to which its emissions are potentially linked. In one case, the EPA's proposed approval of Iowa's SIP submittal, ''*the EPA expended its own resources to attempt to supplement the information submitted by the state,* in order to more thoroughly evaluate the state-specific circumstances that could support approval.'' E.g., 87 FR 9806–07 (emphasis added). The EPA emphasizes again that it was the EPA's sole discretion to perform this analysis in support of the state's submittal, and the Agency is not obligated to conduct supplemental analysis to fill the gaps whenever it believes a state's analysis is insufficient. *Id.*

We acknowledge that certain states may have assumed the EPA would approve SIP submissions from states whose contribution to any receptor was below 1 ppb, but that assumption reflected a misunderstanding of the August 2018 memorandum, and in any case, an assumption is not, as a legal matter, the same thing as a reliance interest.

The EPA is not formally rescinding the August 2018 memorandum in this action or at this time, but since guidance memoranda are not binding in the first place, it is not required that agencies must ''rescind'' a guidance the moment it becomes outdated or called into question. As the Agency made clear in the August 2018 memorandum, all of EPA's proposals for action on interstate transport SIP submissions are subject to rulemaking procedure, including public notice and comment, before the EPA makes a final decision.

Although the EPA is not formally revoking the August 2018 memorandum at this time, and we have separately found that no state successfully established a basis for use of a 1 ppb threshold, we also continue to believe, as set forth in our proposed disapprovals, that national ozone transport policy associated with addressing obligations for the 2015 ozone NAAQS is not well-served by allowing for less protective thresholds at Step 2. Furthermore, the EPA disagrees that national consistency is an inappropriate consideration in the context of interstate ozone transport. The Good Neighbor provision, CAA section 110(a)(2)(D)(i)(I), requires to a unique degree of concern for consistency, parity, and equity across

state lines.[325] For a regional air pollutant such as ozone, consistency in requirements and expectations across all states is essential. Based on the EPA's review of good neighbor SIP submissions to-date and after further consideration of the policy implications of attempting to recognize an alternative Step 2 threshold for certain states, the Agency now believes the attempted use of different thresholds at Step 2 with respect to the 2015 ozone NAAQS raises substantial policy consistency and practical implementation concerns. The availability of different thresholds at Step 2 has the potential to result in inconsistent application of good neighbor obligations based solely on the strength of a state's SIP submission at Step 2 of the 4-step interstate transport framework. From the perspective of ensuring effective regional implementation of good neighbor obligations, the more important analysis is the evaluation of the emissions reductions needed, if any, to address a state's significant contribution after consideration of a multifactor analysis at Step 3, including a detailed evaluation that considers air quality factors and cost. While alternative thresholds for purposes of Step 2 may be ''similar'' in terms of capturing the relative amount of upwind contribution (as described in the August 2018 memorandum), nonetheless, use of an alternative threshold would allow certain states to avoid further evaluation of potential emissions controls while other states with a similar level of contribution would proceed to a Step 3 analysis. This can create significant equity and consistency problems among states.

One comment suggested that the EPA could address this potentially inequitable outcome by simply adopting a 1 ppb contribution threshold for all states. However, the August 2018 memorandum did not conclude that 1 ppb would be appropriate for all states, and the EPA does not view that conclusion to be supported at present. The EPA recognized in the August 2018 memorandum that on a nationwide basis there was some similarity in the amount of total upwind contribution captured between 1 percent and 1 ppb. However, while this may be true in some sense, that is hardly a compelling basis to move to a 1 ppb threshold for every state. Indeed, the 1 ppb threshold has the disadvantage of losing a certain amount of total upwind contribution for further evaluation at Step 3 (*e.g.,* roughly 7 percent of total upwind state contribution was lost according to the modeling underlying the August 2018 memorandum; in the EPA's 2016v2 and 2016v3 modeling, the amount lost is 5 percent). Further, this logic has no end point. A similar observation could be made with respect to any incremental change. For example, should the EPA next recognize a 1.2 ppb threshold because that would only cause some small additional loss in capture of upwind state contribution as compared to 1 ppb? If the only basis for moving to a 1 ppb threshold is that it captures a ''similar'' (but actually smaller) amount of upwind contribution, then there is no basis for moving to that threshold at all. Considering the core statutory objective of ensuring elimination of all significant contribution to nonattainment or interference with maintenance of the NAAQS in other states as well as the broad, regional nature of the collective contribution problem with respect to ozone, we continue to find no compelling policy reason to adopt a new threshold for all states of 1 ppb.

It also is unclear why use of a 1 ppb threshold would be appropriate for all states under a more protective NAAQS when a 1 percent of the NAAQS contribution threshold has been used for less protective NAAQS. To illustrate, a state contributing greater than 0.75 ppb but less than 1 ppb to a receptor under the 2008 ozone NAAQS was ''linked'' at Step 2 using the 1 percent of the NAAQS contribution threshold, but if a 1 ppb threshold were used for the 2015 ozone NAAQS, then that same state would not be ''linked'' to a receptor at Step 2 under a NAAQS that is set to be more protective of human health and the environment. Consistency with past interstate transport actions such as CSAPR, and the CSAPR Update and Revised CSAPR Update rulemakings (which used a Step 2 threshold of 1 percent of the NAAQS for two less protective ozone NAAQS), is an important consideration. Continuing to use a 1 percent of NAAQS approach ensures that if the NAAQS are revised and made more protective, an appropriate increase in stringency at Step 2 occurs, to ensure an appropriately larger amount of total upwind-state contribution is captured for purposes of fully addressing interstate transport obligations. *See* 76 FR 48208, 48237–38.

One comment identified that if the EPA were to use a 1 percent of the NAAQS contribution threshold, the EPA would be obligated to seek feedback on that contribution threshold through a public notice and comment process. The EPA's basis and rationale for every SIP submission covered by this final SIP disapproval action, including the use of a 1 percent of the NAAQS contribution threshold, was in fact presented for public comment. The EPA received, and is addressing in this action, many detailed comments about contribution thresholds. Further, the EPA's application of a 1 percent of the NAAQS threshold has been consistently used in notice-and-comment rulemakings beginning with the CSAPR rulemaking in 2010–2011 and including both FIP actions (CSAPR Update and Revised CSAPR Update) and numerous actions on ozone transport SIP submissions. In each case, the 1 percent of the NAAQS threshold was subject to rigorous vetting through public comment and the Agency's response to those comments, including through analytical evaluations of alternative thresholds. *See, e.g.,* 81 FR 74518–19. By contrast, the August 2018 memorandum was not issued through notice-and-comment rulemaking procedures, and the EPA was careful to caveat its utility and ultimate reliability for that reason.

Comment: Some comments claim that the EPA is applying the August 2018 memorandum inconsistently based on the EPA's actions with regard to action good neighbor SIP submissions from Iowa and Oregon for the 2015 ozone NAAQS and Arizona's good neighbor SIP submission for the 2008 ozone NAAQS.

EPA Response: The EPA disagrees that there is any such inconsistency. The EPA withdrew a previously proposed approval of Iowa's SIP submission where the Agency had attempted to substantiate the use of a 1 ppb contribution threshold, and re-proposed and finalized approval of that SIP based on a different rationale using a 1 percent of the NAAQS contribution threshold. 87 FR 9477 (Feb. 22, 2022); 87 FR 22463 (April 15, 2022). As explained earlier in this section, this experience of the EPA attempting to justify 1 ppb for a state through additional air quality analysis, where the state had not conducted an analysis the Agency considered to be sufficient is part of the reason the Agency is moving away from attempting to justify use of this alternative contribution threshold.

The EPA also disputes the claim that Oregon and Arizona were the only states ''allowed'' to use a 1 ppb threshold. The EPA approved Oregon's SIP submission for the 2015 ozone NAAQS on May 17,

[325] The EPA notes that Congress has placed on the EPA a general obligation to ensure the requirements of the CAA are implemented consistently across states and regions. *See* CAA section 301(a)(2). Where the management and regulation of interstate pollution levels spanning many states is at stake, consistency in application of CAA requirements is paramount.

2019, and both Oregon and the EPA relied on a 1 percent of the NAAQS contribution threshold. 84 FR 7854, 7856 (March 5, 2019) (proposal); 84 FR 22376 (May 17, 2019) (final). In our FIP proposal for the 2015 ozone NAAQS, the EPA explained it was not proposing to conduct an error correction for Oregon even though updated modeling indicated Oregon contributed above 1 percent of the NAAQS to monitors in California, because the specific monitors in California are not interstate ozone transport ''receptors'' at Step 1. *See* 87 FR 20036, 20074–20075 (April 6, 2022). The EPA solicited public comment on its approach to Oregon's contribution to California receptors as part of the 2015 ozone NAAQS transport FIP development, and the Agency has not yet taken final action on that FIP. In 2016, the EPA previously approved Arizona's good neighbor SIP for the earlier 2008 ozone NAAQS based on a similar rationale with regard to certain monitors in California in 2016. 81 FR 15200 (March 22, 2016) (proposal); 81 FR 31513 (May 19, 2016) (final rule). The Agency's view with respect to its evaluation of both Arizona and Oregon is that specific monitors in California are not interstate ozone transport ''receptors'' at Step 1. The EPA has not approved or applied an alternative Step 2 threshold for any state.

Comments related to the specific circumstances of an individual state and/or its arguments put forth in its SIP submission as it pertains to the August 2018 Memorandum are further addressed in the RTC document.

8. Step 3: States' Step 3 Analyses for the 2015 Ozone NAAQS

Comment: Comments state that the EPA has not provided any guidance on what an appropriate Step 3 analysis would entail, and therefore any decision where the Agency rejects a Step 3 analysis is arbitrary and capricious. One comment claims that not a single state has successfully made a Step 3 demonstration leading to an approvable interstate transport SIP for the 2015 ozone NAAQS. Comments note that there is no requirement in the CAA that states must complete an analysis similar to the EPA's, and the EPA cannot substitute its own judgment for that of the state's in crafting a SIP. Rather, the EPA is obligated to defer to state choices. One comment asserts that the EPA is required to interpret the term ''significant contribution'' in a manner ''which ties contribution to an amount which contributes significantly to downwind maintenance or nonattainment problems.'' Another comment claims the EPA is intentionally exploiting the Supreme Court decision in *EME Homer City* to justify any requirements it deems necessary to further Federal policy decisions. Some comments identify that some states did not conduct a Step 3 analysis in their submitted SIPs because, using the flexibilities provided in the 2018 memoranda, these states concluded in Step 1 and Step 2 that no controls were required. One comment suggests that the EPA propose an 18-month period to allow these states to proceed with Steps 3 and 4.

EPA Response: The EPA disagrees that it is obligated to defer to states' choices in the development of good neighbor SIP submissions. As required by the Act, the EPA has evaluated each of the SIP submissions for compliance with the CAA, including whether an adequate Step 3 analysis was conducted—or whether states had offered an approvable alternative approach to evaluating their good neighbor obligations—and found in each case that what these states submitted was not approvable. The Supreme Court has recognized that the EPA is not obligated to provide states with guidance before taking action to disapprove a SIP submission. *EME Homer City,* 572 U.S. at 508–10. Nonetheless, throughout the entire history of the EPA's actions to implement the good neighbor provision for ozone, starting with the 1998 NO_X SIP Call, we have consistently adopted a similar approach at Step 3 that evaluates emissions reduction opportunities for linked states applying a multifactor analysis. States could have performed a similar analysis of emissions control opportunities. The EPA has not directed states that they must conduct a Step 3 analysis in precisely the manner the EPA has done in its prior regional transport rulemakings; however, SIPs addressing the obligations in CAA section 110(a)(2)(D)(i)(I) must prohibit ''any source or other type of emissions activity within the State'' from emitting air pollutants which will contribute significantly to downwind air quality problems. Thus, States seeking to rely on an alternative approach to defining ''significance'' must use an approach that comports with the statute's objectives to determine whether and to what degree emissions from a state should be ''prohibited'' to eliminate emissions that will ''contribute significantly to nonattainment in, or interfere with maintenance of'' the NAAQS in any other state. Further, the approach selected must be reasonable and technically justified. Therefore, while the EPA does not direct states to use a particular framework, nonetheless, each state must show that its decision-making was based on a ''technically appropriate or justifiable'' evaluation.

Further, the Agency has a statutory obligation to review and approve or disapprove SIP submittals according to the requirements of the Clean Air Act. *See* CAA section 110(k)(3). And the Agency is empowered to interpret those statutory requirements and exercise both technical and policy judgment in acting on SIP submissions. Indeed, the task of allocating responsibility for interstate pollution particularly necessitates Federal involvement. *See EME Homer City,* 572 U.S. at 514 (''The statute . . . calls upon the Agency to address a thorny causation problem: How should EPA allocate among multiple contributing upwind States responsibility for a downwind State's excess pollution?''); *see also Wisconsin,* 938 F.3d at 320. Further, we have consistently disapproved states' good neighbor SIP submissions addressing prior ozone NAAQS when we have found those states linked through our air quality modeling and yet the state failed to conduct an analysis of emissions control opportunities, or such analysis was perfunctory or otherwise unsatisfactory. We have been upheld in our judgment that such SIPs are not approvable. *See Westar Energy* v. *EPA,* 608 Fed. App'x 1, 3 (DC Cir. 2015) (''EPA acted *well within the bounds* of its delegated authority when it disapproved of Kansas's proposed SIP.'') (emphasis added).

With respect to the assertion that no state has successfully avoided a FIP with an approvable Step 3 analysis, we note first that at this time, no final FIP addressing the 2015 ozone NAAQS has been promulgated. More directly to the point, no state submission that is the subject of this disapproval action offered any additional emissions control measures. While it is conceivable that a Step 3 analysis may result in a determination that no additional controls are needed, EPA expects that such circumstances will generally be rare, else the CAA's interstate transport provisions are rendered ineffective. For example, the EPA determined in the CSAPR Update that even though the District of Columbia and Delaware were linked to out of state receptors at Steps 1 and 2 of the 4-step interstate transport framework, no additional control measures were required of either jurisdiction. As to the District of Columbia, we found that there were no affected EGU sources that would fall under the CSAPR Update's control program. For Delaware, we found that there were no emissions reductions available from any affected sources for any of the emissions control stringencies that were analyzed. *See* 81 FR 74504, 74553. No state's submission covered in this action contained an emissions control analysis that would allow for these types of conclusions to be reached for all of its sources.[326] States generally did not conduct any comparative analysis of available emissions control strategies—nor did they prohibit any additional ozone-precursor emissions.

We are unclear what another comment intends in asserting that the EPA is required to interpret ''significant contribution'' in a manner ''which ties contribution to an amount which contributes significantly to downwind maintenance or nonattainment problems.'' The EPA disagrees that: (1) It has imposed or mandated a specific approach to Step 3 in this action, (2) this action established a particular level of emissions reduction that states were required to achieve, or (3) it mandated a particular methodology for making such a determination. To the extent the comment suggests that the Agency cannot mandate that states use cost as a method of allocating responsibility in their transport SIPs, first, the Agency has not done so. Further, as to whether cost could be used as a permissible method of allocating responsibility, the comment ignores the Supreme Court's holding to the contrary in *EME Homer City,* 572 U.S. at 518, and the D.C. Circuit's earlier holding to the same effect in *Michigan,* 213 F.3d at 687–88, both of which upheld the EPA's approach of using uniform cost-effectiveness thresholds to allocate upwind state responsibilities under the good neighbor provision for prior NAAQS. While this approach may be reasonable to apply again for the 2015 ozone NAAQS (and the EPA has proposed to do so in the proposed FIP action published on April 6, 2022), the EPA did not impose such a requirement on states in developing SIP submissions, nor is the EPA finding any SIP submission not approvable based on a failure to use this particular methodology.

In its March 2018 memorandum, Attachment A, the Agency acknowledged that there could be multiple ways of conducting a Step 3 analysis. The Agency did not endorse any particular approach and noted the Attachment was merely a list of stakeholder ideas that the EPA was not recommending any state follow. The apparent result of this ''flexibility,'' however, was that no state presented a Step 3 analysis that resulted in including any enforceable emissions reductions to address good neighbor obligations for the 2015 ozone NAAQS in their interstate transport SIP submittals. Likewise, the comment here did not include information or analysis establishing that any particular alternative Step 3 approach should have been approved or that any state performed such an analysis in a manner that would have addressed ''significant contribution'' even in the manner the comment appears to be suggesting.

Notably, materials appended to one State's SIP submission, developed by the Midwest Ozone Group (MOG), did present an analysis applying an approach to ''significant contribution'' that was based on calculating a proportional share of each state's contribution to a downwind receptor, and this methodology would have imposed on that State's, Kentucky's, sources an obligation to eliminate 0.02 ppb of ozone at the relevant receptor. *See* 87 FR 9507. While the EPA does not endorse or here evaluate the merits of such an approach, it is noteworthy that the State in that instance did not adopt that approach, did not impose that obligation on its sources through enforceable measures by revising its SIP, and offered no explanation for its decision not to do so. *See id.* 9516 (''This approach would have imposed additional emissions reductions for Kentucky sources. Kentucky's final SIP did not consider MOG's proposal and did not provide an explanation for why it was rejecting this approach to allocating upwind emissions reductions, even though it appended this recommendation to its SIP submittal.'').

9. Step 4: Attempt To Rely on FIPs in a SIP Submission

Comment: One comment states that FIPs or other Federal emissions control measures do not have to be incorporated into and enforceable under state law to be an approvable SIP measure. They view it as acceptable for a state to rely in its SIP Submission on the emissions reductions achieved by prior ozone transport FIPs, such as the CSAPR Update or the Revised CSAPR Update, as a permissible means of achieving emissions reductions to eliminate significant contribution for the 2015 ozone NAAQS.

EPA Response: The EPA disagrees. As the EPA has noted on page 16 of our September 2013 memorandum ''Guidance on Infrastructure State Implementation Plan (SIP) Elements under Clean Air Act sections 110(a)(1) and 110(a)(2)'' (2013 Infrastructure SIP Guidance): ''a FIP is not a state plan and thus cannot serve to satisfy the state's obligation to submit a SIP.'' [327] Indeed, the general principle that measures relied on to meet states' CAA obligations must be part of the SIP has been recognized by courts, such as in *Committee for a Better Arvin,* 786 F.3d 1169 (9th Cir. 2015).

This principle is grounded in the recognition that if such measures are not rendered enforceable within the SIP itself, then they may be modified or amended in ways that would undermine the basis for the state's reliance on them, while the approved SIP itself would purport to have addressed the relevant obligation merely by outdated reference to that modified or nonexistent control measure residing outside the SIP. For example, to be credited for attainment demonstration purposes, requirements that may otherwise be federally enforceable (such as new source review permit limits or terms in federally enforceable consent orders), must be in the state's implementation plan so that they could not later be changed without being subject to the EPA's approval. This principle is instrumental to ensuring that states cannot take credit for control measures that might be changed (even by the EPA itself) without the EPA's required approval action under CAA section 110, which includes the obligation to ensure there is no interference or backsliding with respect to all applicable CAA requirements. *See* CAA section 110(l). *See also Montana Sulfur and Chemical Co.* v. *EPA,* 666 F.3d 1174, 1195–96 (9th Cir. 2012) (''The EPA correctly reads 42 U.S.C. 7410(a)(2) as requiring states to include enforceable emissions limits and other control measures *in the plan itself.*'') (emphasis in original); 40 CFR 51.112(a) (''Each plan must demonstrate that the measures, rules, and regulations *contained in it* are adequate to provide for the timely attainment and

[326] We note that California's SIP submission is not approvable at Step 3, despite the fact that the EPA has not identified NO_X emissions control opportunities at the state's EGUs. Nonetheless, the SIP submission is not approvable because the state attempted to rely on the CSAPR Update cost threshold to justify a no-control determination when that threshold was in relation to a partial remedy for a less protective NAAQS, and even if it could be reasonably concluded that no emissions reductions are appropriate at EGUs in California, the SIP submission did not conduct an adequate analysis of emissions control opportunities at its non-EGU industrial sources. *See* 87 FR 31459–60.

[327] Guidance on Infrastructure State Implementation Plan (SIP) Elements under Clean Air Act Sections 110(a)(1) and 110(a)(2), September 13, 2013 (available at *https://www.epa.gov/sites/default/files/2015-12/documents/guidance_on_infrastructure_sip_elements_multipollutant_final_sept_2013.pdf*).

maintenance of the national standard that it implements.'') (emphasis added).

The EPA has applied this same interpretation in implementing other infrastructure SIP requirements found in CAA section 110(a)(2). For example, in implementing CAA section 110(a)(2)(C), (D)(i)(II), (D)(ii), and (J) relating to the permitting program for PSD, the EPA has developed FIPs that incorporate by reference provisions codified at 40 CFR 51.21, and some states have taken delegation of that FIP to implement the relevant requirements. But the EPA does not and cannot approve the state as having met these infrastructure SIP elements, even by virtue of taking delegation of the FIP. *See, e.g.,* 83 FR 8818, 8820 (March 1, 2018). Likewise, under one of the pathways presented in our 2013 Infrastructure SIP Guidance, the EPA does not approve SIPs addressing interstate visibility transport obligations under CAA section 110(a)(2)(D)(i)(II) (''prong 4'') until the state itself has a fully approved regional haze plan, and states cannot rely on the CSAPR ''better than BART'' FIPs to meet their prong 4 requirements until they have replaced that FIP with an approved SIP. *See, e.g.,* 84 FR 13800, 13801 (April 8, 2019); 84 FR 43741, 43744 (Aug. 22, 2019).

The comment does not provide contrary examples where the EPA has approved, as a SIP-based emissions control program, requirements that are established through Federal regulation or other types of emissions control programs that are outside the SIP. It is true that in the first two steps of the 4-step interstate transport framework, the EPA conducts air quality modeling based on emissions inventories reflective of on-the-books state and Federal emissions control requirements, to make determinations about air quality conditions and contribution levels that can be anticipated *in the baseline* in a future analytic year. If the comment's examples were intended to reference this consideration of Federal measures in prior actions on SIP submittals, the EPA agrees that it does consider such measures at these steps of its analysis, and the EPA has consistently taken this approach throughout its prior ozone transport actions. But here we are discussing Step 3 and 4 of the framework, where states that have been found to contribute to downwind nonattainment and maintenance problems, *e.g.,* are linked at Steps 1 and 2 to an out of state receptor, would need to evaluate their continuing emissions to determine what if any of those emissions should be deemed ''significant'' (*e.g.,* Step 3) and eliminated through enforceable emissions control requirements (*e.g.,* Step 4). The EPA is not aware of any good neighbor SIP submission that it has approved where a state purported to eliminate its significant contribution (*e.g.,* satisfy Steps 3 and 4) simply by referring to Federal measures that were not included in its SIP and enforceable as a matter of state law. Finally, it bears emphasizing that the EPA's assessment of the 2015 ozone transport SIPs has already accounted for the emissions-reducing effects of both the CSAPR Update and the Revised CSAPR Update in its baseline air quality modeling at Steps 1 and 2, and so pointing to either of those rules as measures that would eliminate significant contribution at Step 3, for purposes of the 2015 ozone NAAQS, would be impermissible double-counting.

C. Good Neighbor Provision Policy

1. Mobile Source Emissions

Comment: Several comments assert that mobile source emissions within the home state of the location of receptors are the primary source of nonattainment problems in downwind areas. Some comments additionally state that a larger portion of their own upwind state emissions is from mobile source emissions. These comments request that the EPA focus on these emissions sources rather than stationary sources to reduce ongoing nonattainment problems. These comments claim mobile sources are federally regulated and, therefore, the EPA bears the responsibility to either take action to reduce mobile source emissions nationwide or encourage downwind states to implement strategies to reduce their own local mobile source emissions.

Response: The EPA recognizes that nationwide, mobile sources represent a large portion of ozone-precursor emissions and, as such, would be expected to have a large impact on nonattainment and maintenance receptors.

The EPA has been regulating mobile source emissions since it was established as a Federal agency in 1970 and is committed to continuing the effective implementation and enforcement of current mobile source emissions standards and evaluating the need for additional standards.[328] The EPA believes that the NO_X reductions from its Federal programs are an important reason for the historical and long-running trend of improving air quality in the United States. The trend helps explain why the overall number of receptors and severity of ozone nonattainment problems under the 1997 and 2008 ozone NAAQS have declined. As a result of this long history, NO_X emissions from onroad and nonroad mobile sources have substantially decreased and are predicted to continue to decrease into the future as newer vehicles and engines that are subject to the more recent and more stringent standards replace older vehicles and engines.[329]

The EPA included mobile source emissions in the 2016v2 modeling used to support the proposal of these SIP disapproval actions to help determine state linkages at Steps 1 and 2 of the 4-step interstate transport framework and has done likewise in its 2016v3 modeling. However, whether mobile source emissions are a large portion of an upwind or downwind state's NO_X emissions, and whether they represent a large portion of the contribution to downwind nonattainment and maintenance receptors, does not answer the question regarding the adequacy of an upwind state's SIP submission. The question is whether ''any source or other type of emissions activity'' (in the collective) in an upwind state is contributing significantly to downwind receptors, *see* CAA section 110(a)(2)(D)(i). A state's transport SIP must include a technical and adequate justification to support its conclusion that the state has satisfied its interstate transport obligations for the 2015 ozone NAAQS.

To the extent that comments argue that mobile source emissions should be the focus of emissions reductions for the purposes of resolving interstate transport obligations, states could have provided such an analysis for how mobile source reductions might achieve necessary reductions. *See, e.g.,* 70 FR 25209. However, states conducted no such analysis of methods or control techniques that could be used to reduce mobile source emissions, instead claiming that states cannot control mobile source emissions, as this is a federally-regulated sector, or states cannot reasonably control these emissions. States do have options, however, to reduce emissions from certain aspects of their mobile source

[328] On December 20, 2022, the EPA finalized more stringent emissions standards for NO_X and other pollutants from heavy-duty vehicles and engines, beginning with model year 2027. *See https://www.epa.gov/regulations-emissions-vehicles-and-engines/final-rule-and-related-materials-control-air-pollution.* The EPA is also developing new multi-pollutant standards for light- and medium-duty vehicles as well as options to address pollution from locomotives.

[329] *https://gispub.epa.gov/air/trendsreport/2022/#home.*

sectors, and to the extent a state is attributing its contribution to out of state receptors to its mobile sources, it could have conducted an analysis of possible programs or measures that could achieve emissions reductions from those sources. (For example, a general list of types of transportation control measures can be found in CAA section 108(f).[330])

State-specific issues raised by comments are further addressed in the RTC document.

2. International Contributions

Comment: Several comments state that international emissions contribute to nonattainment and maintenance receptors downwind, and these emissions are not within the jurisdiction of the states. They advocate for the EPA should considering this when acting on SIP submissions. Some comments claim that, in the west, international contributions are even greater than in eastern portions of the U.S. and support their notion that the EPA's evaluation of interstate transport should take special consideration of unique regional factors when determining upwind state obligations, or that the Agency should otherwise explain why it is still inappropriate to factor in higher international contributions, as the Agency has done in Oregon's case.

Response: The EPA responded to similar arguments related to international emissions included in the SIP submissions of Arkansas, California, Illinois, Indiana, Kentucky, Michigan, Missouri, Ohio, Utah, Wyoming, and West Virginia in the proposed disapprovals.[331] No comments on the proposed disapprovals provided new information to indicate the EPA's initial assessment was incorrect. These comments' reasoning related to international emissions is inapplicable to the requirements of CAA section 110(a)(2)(D)(i)(I). The good neighbor provision requires states and the EPA to address interstate transport of air pollution that significantly contributes to downwind states' ability to attain and maintain the NAAQS. Whether emissions from other states or other countries also contribute to the same downwind air quality issue is typically not relevant in assessing whether a downwind state has an air quality problem, or whether an upwind state is significantly contributing to that problem. (Only in rare cases has EPA concluded that certain monitoring sites should not be considered receptors at Step 1 due to the very low collective upwind-state contribution at those receptors. *See* the RTC document.) States are not obligated under CAA section 110(a)(2)(D)(i)(I) to act alone to reduce emissions in amounts sufficient to resolve a downwind receptor's nonattainment or maintenance problem. Rather, states are obligated to eliminate their own ''significant contribution'' to that receptor or ''interference'' with the ability of other states to attain or maintain the NAAQS. The statutory standard is, fundamentally, one of contribution, not causation.

Indeed, the D.C. Circuit in *Wisconsin* specifically rejected petitioner arguments suggesting that upwind states should be excused from good neighbor obligations on the basis that some other source of emissions (whether international or another upwind state) could be considered the ''but-for'' cause of downwind air quality problem. *See Wisconsin,* 938 F.3d at 323–324. The court viewed petitioners' arguments as essentially an argument ''that an upwind state 'contributes significantly' to downwind nonattainment only when its emissions are the sole cause of downwind nonattainment.'' *Id.* at 324. The court explained that ''an upwind state can 'contribute' to downwind nonattainment even if its emissions are not the but-for cause.'' *Id.* at 324–325. *See* also *Catawba County* v. *EPA,* 571 F.3d 20, 39 (DC Cir. 2009) (rejecting the argument ''that 'significantly contribute' unambiguously means 'strictly cause''' because there is ''no reason why the statute precludes EPA from determining that [an] addition of [pollutant] into the atmosphere is significant even though a nearby county's nonattainment problem would still persist in its absence''); *Miss. Comm'n on Envtl. Quality* v. *EPA,* 790 F.3d 138, 163 n.12 (DC Cir. 2015) (observing that the argument that ''there likely would have been no violation at all . . . if it were not for the emissions resulting from [another source]'' is ''merely a rephrasing of the but-for causation rule that we rejected in Catawba County''). Therefore, a state is not excused from eliminating its significant contribution on the basis that international emissions also contribute some amount of pollution to the same receptors to which the state is linked.

To the extent comments compare the influence of international emissions with the EPA's treatment of receptors in California to which Oregon contributes greater than 0.70 ppb, the EPA responds to these comments in the RTC document.

3. Western Interstate Transport Policy

Comment: Several comments argue that the EPA should consider an alternative approach to evaluating interstate transport in the western U.S. Comments assert there are considerations unique to the western states, such as increased background, international, and wildfire contributions to ozone concentrations in the west. Some commenters believe a ''case-by-case'' assessment is more appropriate for evaluating western states' interstate transport obligations, as they claim the EPA had done for the 2008 ozone standards. They additionally argue that the EPA modeling is not able to accurately project ozone concentrations in the west because of these factors, along with the west's unique topographical influence on ozone transport.

Response: The EPA disagrees that either its nationwide photochemical grid modeling or the 4-step interstate transport framework for ozone cannot generally be applied to states in the western region of the U.S. and has maintained that position consistently throughout numerous actions.[332] Though at times the EPA has found it appropriate to examine more closely discreet issues for some western states,[333] the 4-step interstate transport framework itself is appropriate for assessing good neighbor obligations of western states in the absence of those circumstances. The EPA evaluated the contents of the western states' SIP submissions covered by this action on the merits of the information the states provided. As described at proposal and reiterated in Section IV, the EPA is finalizing its disapproval of California,

[330] In making this observation, the EPA is not suggesting that mobile source emissions reductions are necessarily required to address a state's good neighbor obligations, but merely pointing out that if the state itself attributes the problem to mobile sources, then it is reasonable to expect that further analysis of such control strategies would be explored.

[331] 87 FR 9798, 9809–9810 (Feb. 22, 2022) (Arkansas); 87 FR 31443, 31460–31461 (May 24, 2022) (California); 87 FR 9854 (Illinois); 87 FR 9859–9860 (Indiana); 87 FR 9498, 9508 (Feb. 22, 2022) (Kentucky); 87 FR 9838, 9865 (Michigan); 87 FR 9533, 9543 (Feb. 22, 2022) (Missouri); 87 FR 9838 at 9874 (Ohio); 87 FR 31470, 31482 (May 24, 2022) (Utah); 87 FR 9516, 9527 (Feb. 22, 2022) (West Virginia); 87 FR 31495, 31507 (May 24, 2022) (Wyoming).

[332] For a discussion of this history, *see* for example 87 FR 31480–81 (proposed disapproval of Utah SIP submission) and 87 FR 31453–56 (proposed disapproval of California SIP submission).

[333] *See, e.g.,* Approval of Arizona's 2008 ozone NAAQS interstate transport SIP submission, 81 FR 15200 (March 22, 2016) (Step 1 analysis concluding certain monitors in California should not be considered interstate transport receptors for purposes of the good neighbor provision for the 2008 ozone NAAQS); *see also* 87 FR 61249, 61254–55 (Oct. 11, 2022) (in approving Colorado's interstate transport SIP for the 2015 ozone NAAQS, analyzing unique issues associated with wintertime inversion conditions in certain western areas).

Nevada, and Utah's SIP submissions. This final determination is based on these evaluations, as well as the EPA's 2016v2 and 2016v3 modeling following stakeholder feedback.

The EPA continues to find it appropriate to rely on the results of its nationwide modeling in the western U.S., despite comments concerning the ability for the EPA's modeling to accurately project ozone concentrations and contributions in western states, as well as its ability to support the EPA's 4-step framework for assessing interstate transport. The EPA's nationwide photochemical grid modeling considers multiple complex factors, including those raised in comments, such as terrain complexities, variability in emissions (*e.g.,* wildfire emissions), meteorology, and topography. While the EPA continues to believe its 2016v2 modeling performs equally as well in both the west and the east, the EPA has adjusted its 2016v3 modeling to ensure its predictions more closely replicate the relative magnitude of concentrations and day-to-day variability that are characteristic of observed 8-hour daily maximum ozone concentrations in each region, as explained in Section III.A and the RTC document. As such, the EPA continues to find its modeling reliable for characterizing ozone concentrations and contribution values in the western U.S. Further responses regarding the reliability of the EPA's modeling in the western U.S. is provided in the RTC document.

The EPA disagrees with comments noting that the Agency took an alternative approach for western states when assessing interstate transport obligations under the 2008 ozone NAAQS. As explained in our proposed disapproval of California's 2015 ozone NAAQS interstate transport SIP submission, while the EPA has in limited circumstances found unique issues associated with addressing ozone transport in western states, the EPA has consistently applied the 4-step interstate transport framework in western states, as it has done here, and has identified ozone transport problems in the west that are similar to those in the east.[334] [335] At proposal, the EPA addressed states' arguments regarding the impact of unique factors such as topography and, as part of the EPA's evaluation of the contents of the SIP submission, provided explanation as to why the EPA found the states' arguments did not support their conclusions regarding long range transport of ozone in the west.[336]

While comments point to relatively higher level of contributions from non-anthropogenic, local, or international contributions in the west as reason for evaluating interstate transport differently in the west, a state is not excused from eliminating its significant contribution due to contributions from these sources, where the data shows that anthropogenic emissions from upwind states also contribute collectively to identified receptors at levels that indicate there to be an interstate contribution problem as well. As stated in Section V.C.2, a state is not excused from eliminating its significant contribution on the basis that international emissions also contribute some amount of pollution to the same receptors to which the state is linked. This same principle applies broadly to other arguments as to which emissions are the ''cause'' of the problem; the good neighbor provision established a contribution standard, not a but-for causation standard. *See Wisconsin,* 938 F.3d at 323–25.

[334] 87 FR 31443, 31453.

[335] 81 FR 74503, 74523.

[336] *See, e.g.,* 87 FR 31443, 31457. The EPA evaluated California's qualitative consideration of unique topographic factors that may influence the transport of emissions from sources within the state to downwind receptors in Colorado and Arizona. The EPA concluded that the State's arguments do not present sufficient evidence that called into question the results of the EPA's modeling.

VI. Statutory and Executive Order Reviews

Additional information about these statutes and Executive orders can be found at *https://www.epa.gov/laws-regulations/laws-and-executive-orders.*

A. Executive Orders 12866: Regulatory Planning and Executive Order 13563: Improving Regulation and Regulatory Review

This action is not a significant regulatory action and was, therefore, not submitted to the Office of Management and Budget for review.

B. Paperwork Reduction Act (PRA)

This action does not impose an information collection burden under the provisions of the Paperwork Reduction Act. This final action does not establish any new information collection requirement apart from what is already required by law. This finding relates to the requirement in the CAA for states to submit SIPs under CAA section 110(a)(2)(D)(i)(I) addressing interstate transport obligations associated with the 2015 ozone NAAQS.

C. Regulatory Flexibility Act (RFA)

I certify that this action will not have a significant economic impact on a substantial number of small entities under the RFA. This action will not impose any requirements on small entities. This action is disapproving SIP submissions for not containing the necessary provisions to satisfy interstate transport requirements under CAA section 110(a)(2)(D)(i)(I).

D. Unfunded Mandates Reform Act of 1995 (UMRA)

This action does not contain any unfunded mandate as described in UMRA 2 U.S.C. 1531–1538 and does not significantly or uniquely affect small governments. The action imposes no enforceable duty on any state, local or tribal governments or the private sector.

E. Executive Order 13132: Federalism

This action does not have federalism implications. It will not have substantial direct effects on the states, on the relationship between the National Government and the states, or on the distribution of power and responsibilities among the various levels of government.

F. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments

This action has tribal implications. However, this action does not impose substantial direct compliance costs on federally recognized tribal governments, nor preempt tribal law. This action includes disapproving the portion of Oklahoma's SIP submission addressing the state's good neighbor obligations under CAA section 110(a)(2)(D)(i)(I) for the 2015 ozone NAAQS and applies to certain areas of Indian country as discussed in Section IV.C of the proposed action, ''Air Plan Disapproval; Arkansas, Louisiana, Oklahoma, and Texas; Interstate Transport of Air Pollution for the 2015 Ozone National Ambient Air Quality Standards'' (87 FR 9798 at 9824, February 2, 2022). However, this action does not impose substantial direct compliance costs on federally recognized tribal governments because no actions will be required of tribal governments. This action will also not preempt tribal law as no Oklahoma tribe implements a regulatory program under the CAA, and thus does not have applicable or related tribal laws. The EPA consulted with tribal officials under the EPA Policy on Consultation and Coordination with Indian Tribes early in the process of developing this regulation to permit them to have meaningful and timely input into its development. A summary of that consultation is provided in the file ''2015 Ozone Transport OK Tribal Consultation Meeting Record 3–3–2022,'' in the docket for this action.

G. Executive Order 13045: Protection of Children From Environmental Health and Safety Risks

The EPA interprets Executive Order 13045 as applying only to those regulatory actions that concern health or safety risks that the EPA has reason to believe may disproportionately affect children, per the definition of ''covered regulatory action'' in section 2–202 of the Executive order. This action is not subject to Executive Order 13045 because it merely disapproves SIP submissions as not containing the necessary provisions to satisfy interstate transport requirements under CAA section 110(a)(2)(D)(i)(I).

H. Executive Order 13211: Actions That Significantly Affect Energy Supply, Distribution or Use

This action is not subject to Executive Order 13211, because it is not a significant regulatory action under Executive Order 12866.

I. National Technology Transfer and Advancement Act (NTTAA)

This rulemaking does not involve technical standards.

J. Executive Order 12898: Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations

Executive Order 12898 (Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations, 59 FR 7629, Feb. 16, 1994) directs Federal agencies to identify and address ''disproportionately high and adverse human health or environmental effects'' of their actions on minority populations and low-income populations to the greatest extent practicable and permitted by law. The EPA defines environmental justice (EJ) as ''the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies.'' The EPA further defines the term fair treatment to mean that ''no group of people should bear a disproportionate burden of environmental harms and risks, including those resulting from the negative environmental consequences of industrial, governmental, and commercial operations or programs and policies.''

Under the CAA, the Administrator is required to approve a SIP submission that complies with the provisions of the Act and applicable Federal regulations. 42 U.S.C. 7410(k); 40 CFR 52.02(a). Thus, in reviewing SIP submissions, the EPA's role is to review state choices, and approve those choices if they meet the minimum criteria of the Act. As articulated in this final action, the EPA is determining that certain SIPs do not meet certain minimum requirements, and the EPA is disapproving those SIPs. Specifically, this action disapproves certain SIP submissions as not containing the necessary provisions to satisfy ''good neighbor'' requirements under CAA section 110(a)(2)(D)(i)(I). The EPA did not perform an EJ analysis and did not consider EJ in this action. The CAA and applicable implementing regulations neither prohibit nor require such an evaluation. In a wholly separate regulatory action, the EPA will fully address the CAA ''good neighbor'' requirements under section 110(a)(2)(D)(i)(I) for the 2015 ozone NAAQS as it regards the SIP disapprovals included in this final action. Consideration of EJ is not required as part of this action, and there is no information in the record inconsistent with the stated goal of E.O. 12898 of achieving EJ for people of color, low-income populations, and Indigenous peoples.

K. Congressional Review Act (CRA)

This action is subject to the CRA, and the EPA will submit a rule report to each House of the Congress and to the Comptroller General of the United States. This action is not a ''major rule'' as defined by 5 U.S.C. 804(2).

L. Judicial Review

Section 307(b)(1) of the CAA governs judicial review of final actions by the EPA. This section provides, in part, that petitions for review must be filed in the D.C. Circuit: (i) when the agency action consists of ''nationally applicable regulations promulgated, or final actions taken, by the Administrator,'' or (ii) when such action is locally or regionally applicable, but ''such action is based on a determination of nationwide scope or effect and if in taking such action the Administrator finds and publishes that such action is based on such a determination.'' For locally or regionally applicable final actions, the CAA reserves to the EPA complete discretion whether to invoke the exception in (ii).[337]

This rulemaking is ''nationally applicable'' within the meaning of CAA section 307(b)(1). In this final action, the EPA is applying a uniform legal interpretation and common, nationwide analytical methods with respect to the requirements of CAA section 110(a)(2)(D)(i)(I) concerning interstate transport of pollution (*i.e.,* ''good neighbor'' requirements) to disapprove SIP submissions that fail to satisfy these requirements for the 2015 ozone NAAQS. Based on these analyses, the EPA is disapproving SIP submittals for the 2015 ozone NAAQS for 21 states located across a wide geographic area in eight of the ten EPA Regions and ten Federal judicial circuits. Given that on its face this action addresses implementation of the good neighbor requirements of CAA section 110(a)(2)(D)(i)(I) in a large number of states located across the country and given the interdependent nature of interstate pollution transport and the common core of knowledge and analysis involved in evaluating the submitted SIPs, this is a ''nationally applicable'' action within the meaning of CAA section 307(b)(1).

In the alternative, to the extent a court finds this action to be locally or regionally applicable, the Administrator is exercising the complete discretion afforded to him under the CAA to make and publish a finding that this action is based on a determination of ''nationwide scope or effect'' within the meaning of CAA section 307(b)(1). In this final action, the EPA is interpreting and applying section 110(a)(2)(D)(i)(I) of the CAA for the 2015 ozone NAAQS based on a common core of nationwide policy judgments and technical analysis concerning the interstate transport of pollutants throughout the continental U.S. In particular, the EPA is applying here the same, nationally consistent 4-step interstate transport framework for assessing obligations for the 2015 ozone NAAQS that it has applied in other nationally applicable rulemakings, such as CSAPR, the CSAPR Update, and the Revised CSAPR Update. The EPA is relying on the results from nationwide photochemical grid modeling using a 2016 base year and 2023 projection year as the primary basis for its assessment of air quality conditions and pollution contribution levels at Step 1 and Step 2 of that 4-step framework and applying a nationally uniform approach to the identification of nonattainment and

[337] In deciding whether to invoke the exception by making and publishing a finding that an action is based on a determination of nationwide scope or effect, the Administrator takes into account a number of policy considerations, including his judgment balancing the benefit of obtaining the D.C. Circuit's authoritative centralized review versus allowing development of the issue in other contexts and the best use of agency resources.

maintenance receptors across the entire geographic area covered by this final action.[338] The EPA has also evaluated each state's arguments for the use of alternative approaches or alternative sets of data with an eye to ensuring national consistency and avoiding inconsistent or inequitable results among upwind states (*i.e.,* those states for which good neighbor obligations are being evaluated in this action) and between upwind and downwind states (*i.e.,* those states that contain receptors signifying ozone nonattainment or maintenance problems).

The Administrator finds that this is a matter on which national uniformity in judicial resolution of any petitions for review is desirable, to take advantage of the D.C. Circuit's administrative law expertise, and to facilitate the orderly development of the basic law under the Act. The Administrator also finds that consolidated review of this action in the D.C. Circuit will avoid piecemeal litigation in the regional circuits, further judicial economy, and eliminate the risk of inconsistent results for different states, and that a nationally consistent approach to the CAA's mandate concerning interstate transport of ozone pollution constitutes the best use of agency resources. The EPA's responses to comments on the appropriate venue for petitions for review are contained in the RTC document.

For these reasons, this final action is nationally applicable or, alternatively, the Administrator is exercising the complete discretion afforded to him by the CAA and finds that this final action is based on a determination of nationwide scope or effect for purposes of CAA section 307(b)(1) and is publishing that finding in the **Federal Register**. Under section 307(b)(1) of the CAA, petitions for judicial review of this action must be filed in the United States Court of Appeals for the District of Columbia Circuit by April 14, 2023.

List of Subjects in 40 CFR Part 52

Environmental protection, Air pollution control, Incorporation by reference, Ozone.

Michael S. Regan,
Administrator.

For the reasons set forth in the preamble, 40 CFR part 52 is amended as follows:

PART 52—APPROVAL AND PROMULGATION OF IMPLEMENTATION PLANS

■ 1. The authority citation for part 52 continues to read as follows:

Authority: 42 U.S.C. 7401 *et seq.*

Subpart B—Alabama

■ 2. Section 52.56 is added to read as follows:

§ 52.56 Control strategy: Ozone.

(a) The state implementation plan (SIP) revision submitted on June 21, 2022, addressing Clean Air Act section 110(a)(2)(D)(i)(I) (prongs 1 and 2) for the 2015 ozone national ambient air quality standards (NAAQS) is disapproved.

(b) [Reserved]

Subpart E—Arkansas

■ 3. Section 52.174 is amended by adding paragraph (b) to read as follows:

§ 52.174 Control strategy and regulations: Ozone.

* * * * *

(b) The portion of the SIP submittal from October 10, 2019, addressing Clean Air Act section 110(a)(2)(D)(i)(I) for the 2015 ozone national ambient air quality standards (NAAQS) is disapproved.

Subpart F—California

■ 4. Section 52.223 is amended by adding paragraph (p)(7) to read as follows:

§ 52.223 Approval status.

* * * * *

(p) * * *

(7) The interstate transport requirements for Significant Contribution to Nonattainment (Prong 1) and Interstate Transport—Interference with Maintenance (Prong 2) of Clean Air Act (CAA) section 110(a)(2)(D)(i)(I).

■ 5. Section 52.283 is amended by adding paragraph (h) to read as follows:

§ 52.283 Interstate Transport.

* * * * *

(h) *2015 ozone NAAQS.* The 2018 Infrastructure SIP Revision, submitted on October 1, 2018, does not meet the following specific requirements of Clean Air Act section 110(a)(2)(D)(i)(I) for the 2015 ozone national ambient air quality standards (NAAQS).

(1) The requirements of CAA section 110(a)(2)(D)(i)(I) regarding significant contribution to nonattainment of the 2015 ozone NAAQS in any other State and interference with maintenance of the 2015 ozone NAAQS by any other State.

(2) [Reserved]

Subpart O—Illinois

■ 6. Section 52.720 is amended in the table in paragraph (e), under the heading "Section 110(a)(2) Infrastructure Requirements," by revising the entry for "2015 Ozone NAAQS Infrastructure Requirements" to read as follows:

§ 52.720 Identification of plan.

* * * * *

(e) * * *

EPA-APPROVED ILLINOIS NONREGULATORY AND QUASI-REGULATORY PROVISIONS

Name of SIP provision	Applicable geographic or non-attainment area	State submittal date	EPA approval date	Comments
* * * * * * *				
Section 110(a)(2) Infrastructure Requirements				

[338] In the report on the 1977 Amendments that revised section 307(b)(1) of the CAA, Congress noted that the Administrator's determination that the "nationwide scope or effect" exception applies would be appropriate for any action that has a scope or effect beyond a single judicial circuit. *See* H.R. Rep. No. 95–294 at 323, 324, reprinted in 1977 U.S.C.C.A.N. 1402–03.

EPA-APPROVED ILLINOIS NONREGULATORY AND QUASI-REGULATORY PROVISIONS—Continued

2015 Ozone NAAQS Infrastructure Requirements.	Statewide ...	5/16/2019 and 9/22/2020.	2/13/2023, [INSERT **FEDERAL REGISTER** CITATION].	All CAA infrastructure elements under 110(a)(2) have been approved except (D)(i)(I) Prongs 1, 2, which are disapproved, and no action has been taken on (D)(i)(II) Prong 4.

Subpart P—Indiana

■ 7. Section 52.770 is amended in the table in paragraph (e) by adding an entry for "Section 110(a)(2) Infrastructure Requirements for the 2015 Ozone NAAQS" after the entry for "Section 110(a)(2) Infrastructure Requirements for the 2008 8-Hour Ozone NAAQS" to read as follows:

§ 52.770 Identification of plan.

* * * * *

(e) * * *

EPA-APPROVED INDIANA NONREGULATORY PROVISIONS AND QUASI-REGULATORY PROVISIONS

Title	Indiana date	EPA approval	Explanation
* *	*	*	* * *
Section 110(a)(2) Infrastructure Requirements for the 2015 Ozone NAAQS.	11/2/2018	2/13/2023, [INSERT **FEDERAL REGISTER** CITATION].	All CAA infrastructure elements have been approved except (D)(i)(I) Prongs 1 and 2, which are disapproved, and no action has been taken on the visibility portion of (D)(i)(II).
* *	*	*	* * *

Subpart S—Kentucky

■ 8. Section 52.930 is amended by adding paragraph (n) to read as follows:

§ 52.930 Control strategy: Ozone.

* * * * *

(n) *Disapproval.* The state implementation plan (SIP) revision submitted on January 11, 2019, addressing Clean Air Act section 110(a)(2)(D)(i)(I) (prongs 1 and 2) for the 2015 ozone national ambient air quality standards (NAAQS) is disapproved.

Subpart T—Louisiana

■ 9. Section 52.996 is amended by adding paragraph (b) to read as follows:

§ 52.996 Disapprovals.

* * * * *

(b) The SIP submittal from November 13, 2019, addressing Clean Air Act section 110(a)(2)(D)(i)(I) for the 2015 ozone NAAQS is disapproved.

Subpart V—Maryland

■ 10. Section 52.1076 is amended by adding paragraph (gg) to read as follows:

§ 52.1076 Control strategy plans for attainment and rate-of-progress: Ozone.

* * * * *

(gg) *Disapproval.* EPA is disapproving Maryland's October 16, 2019, State Implementation Plan (SIP) revision intended to address the Clean Air Act (CAA) section 110(a)(2)(D)(i)(I) interstate transport requirements for the 2015 8-hour ozone national ambient air quality standard (NAAQS).

Subpart X—Michigan

■ 11. Section 52.1170 is amended in the table in paragraph (e), under the heading "Infrastructure," by revising the entry for "Section 110(a)(2) infrastructure requirements for the 2015 ozone NAAQS" to read as follows:

§ 52.1170 Identification of plan.

* * * * *

Subpart Z—Mississippi

■ 13. Section 52.1273 is amended by adding paragraph (b) read as follows:

§ 52.1273 Control strategy: Ozone.

* * * * *

(b) *Disapproval.* The state implementation plan (SIP) revision submitted on September 3, 2019, addressing Clean Air Act section 110(a)(2)(D)(i)(I) (prongs 1 and 2) for the 2015 ozone national ambient air quality standards (NAAQS) is disapproved.

Subpart AA—Missouri

■ 14. Section 52.1323 is amended by adding paragraph (p) to read as follows:

§ 52.1323 Approval status.

* * * * *

(p) For the 2015 8-hour ozone NAAQS:

(1) *Disapproval.* Missouri state implementation plan (SIP) revision submitted on June 10, 2019, to address the Clean Air Act (CAA) infrastructure requirements of section 110(a)(2) for the 2015 8-hour ozone NAAQS, is disapproved for section 110(a)(2)(D)(i)(I) (prongs 1 and 2).

(2) [Reserved]

Subpart DD—Nevada

■ 15. Section 52.1472 is amended by adding paragraph (k) to read as follows:

§ 52.1472 Approval status.

* * * * *

(k) *2015 8-hour ozone NAAQS.* The SIP submittal from October 1, 2018, is disapproved for Clean Air Act (CAA) section 110(a)(2)(D)(i)(I) (prongs 1 and 2) for the NDEP, Clark County, and Washoe County portions of the Nevada SIP submission.

Subpart FF—New Jersey

■ 16. Section 52.1586 is amended by adding paragraph (c) and reserved paragraph (d) to read as follows:

§ 52.1586 Section 110(a)(2) infrastructure requirements.

* * * * *

(c) *2015 8-hour ozone NAAQS*—(1) *Disapproval.* New Jersey SIP revision submitted on May 13, 2019, to address the CAA infrastructure requirements of section 110(a)(2) for the 2015 8-hour ozone NAAQS, is disapproved for section 110(a)(2)(D)(i)(I) (prongs 1 and 2).

(2) [Reserved]

(d) [Reserved]

Subpart HH—New York

■ 17. Section 52.1683 is amended by adding paragraph (v) to read as follows:

§ 52.1683 Control strategy: Ozone.

* * * * *

(v) *Disapproval.* The portion of the SIP revision submitted on September 25, 2018, addressing Clean Air Act section 110(a)(2)(D)(i)(I) (prongs 1 and 2) for the 2015 ozone NAAQS is disapproved.

Subpart KK—Ohio

■ 18. Section 52.1870 is amended in the table in paragraph (e), under ''Infrastructure Requirements,'' by revising the entry for ''Section 110(a)(2) infrastructure requirements for the 2015 ozone NAAQS'' to read as follows:

§ 52.1870 Identification of plan.

* * * * *

(e) * * *

RIN 2060–AV51

Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standard

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule.

SUMMARY: This action proposes Federal Implementation Plan (FIP) requirements to address twenty-six states' obligations to eliminate significant contribution to nonattainment, or interference with maintenance, of the 2015 ozone National Ambient Air Quality Standard (NAAQS) in other states. The U.S. Environmental Protection Agency (EPA) is proposing this action under the ''good neighbor'' or ''interstate transport'' provision of the Clean Air Act (CAA or Act). The Agency proposes establishing nitrogen oxides emissions budgets requiring fossil fuel-fired power plants in 25 states to participate in an allowance-based ozone season trading program beginning in 2023. The Agency is also proposing to establish nitrogen oxides emissions limitations applicable to certain other industrial stationary sources in 23 states with an earliest possible compliance date of 2026. These industrial source types are: Reciprocating internal combustion engines in Pipeline Transportation of Natural Gas; kilns in Cement and Cement Product Manufacturing; boilers and furnaces in Iron and Steel Mills and Ferroalloy Manufacturing; furnaces in Glass and Glass Product Manufacturing; and high-emitting equipment and large boilers in Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mills.

DATES: Comments must be received on or before June 6, 2022.

Public Hearing: The EPA will hold a virtual public hearing on April 21, 2022. Please refer to the **SUPPLEMENTARY INFORMATION** section for additional information on the public hearing.

Information Collection Request (ICR): Under the Paperwork Reduction Act (PRA), comments on the information collection provisions are best assured of consideration if the Office of Management and Budget (OMB) receives a copy of your comments on or before May 6, 2022.

ADDRESSES: You may send comments, identified by Docket ID No. EPA–HQ–OAR–2021–0668; via the Federal eRulemaking Portal: *https://www.regulations.gov/* (our preferred method). Follow the online instructions for submitting comments.

Instructions: All submissions received must include the Docket ID No. for this rulemaking. Comments received may be posted without change to *https://www.regulations.gov/,* including any personal information provided. For detailed instructions on sending comments and additional information on the rulemaking process, see the ''Public Participation'' heading of the **SUPPLEMENTARY INFORMATION** section of this document. Out of an abundance of caution for members of the public and our staff, the EPA Docket Center and Reading Room are open to the public by appointment only to reduce the risk of transmitting COVID–19. Our Docket Center staff also continues to provide remote customer service via email, phone, and webform. Hand deliveries and couriers may be received by scheduled appointment only. For further information on EPA Docket Center services and the current status, please visit us online at *https://www.epa.gov/dockets.*

The virtual public hearing will be held on April 21, 2022. The virtual public hearing will convene at 10 a.m. Eastern Time (ET) and will conclude at 7 p.m. ET. The EPA may close a session 15 minutes after the last pre-registered speaker has testified if there are no additional speakers. For information or questions about the public hearing, please contact Ms. Holly DeJong at *Dejong.holly@epa.gov.* The EPA will announce further details at *https://www.epa.gov/csapr/csapr-2015-ozone-naaqs.* Refer to the **SUPPLEMENTARY INFORMATION** section for additional information.

I. Executive Summary

This proposed rule would resolve the interstate transport obligations of 26 states under CAA section 110(a)(2)(D)(i)(I), referred to as the ''good neighbor provision'' or the ''interstate transport provision'' of the Act, for the 2015 ozone NAAQS. On October 1, 2015, the EPA revised the primary and secondary 8-hour standards for ozone to 70 parts per billion (ppb).[1] States were required to provide ozone infrastructure State Implementation Plan (SIP) submissions to fulfill interstate transport obligations for the 2015 ozone NAAQS by October 1, 2018.

The EPA proposes to make a finding that interstate transport of ozone precursor emissions from 26 upwind states (Alabama, Arkansas, California, Delaware, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Tennessee, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming) is significantly contributing to downwind nonattainment or interfering with maintenance of the 2015 ozone NAAQS in other states, based on projected nitrogen oxides (NO_X) emissions in the 2023 ozone season. The EPA is proposing to issue FIP requirements to eliminate interstate transport of ozone precursors from these 26 states that significantly contributes to nonattainment or interferes with maintenance of the NAAQS in other states.

The EPA is proposing FIPs for 23 states for which the Agency has not approved an ozone transport SIP that was submitted for the 2015 ozone NAAQS: Alabama, Arkansas, California, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Tennessee, Texas, Utah, West Virginia, Wisconsin, and Wyoming. In this proposed rule, the EPA is proposing to issue FIPs for two states—Pennsylvania and Virginia—for which the EPA issued a Finding of Failure to Submit for 2015 ozone transport SIPs with an effective date of January 6, 2020. Under CAA section 301(d)(4), the EPA proposes to extend FIP requirements to apply in Indian country located within the upwind geography of the proposed rule, including Indian reservation lands and other areas of Indian country over which the EPA or a tribe has demonstrated that a tribe has jurisdiction.[2] The EPA is also proposing a FIP for Delaware and an error correction for the Agency's May 1, 2020, approval at 85 FR 25307 of the interstate transport elements for Delaware's October 11, 2018, and December 26, 2019, ozone infrastructure SIP submissions.

In this proposed rule, the EPA proposes to establish new ozone season NO_X emissions budgets beginning in 2023 for Electric Generating Unit (EGU) sources. The EPA is also proposing to establish emissions limitations beginning in 2026 for certain other industrial stationary sources (referred to generally as ''non-Electric Generating Units'' (non-EGUs)). Taken together, these strategies will fully eliminate the covered states' significant contribution to downwind ozone air quality problems in other states.

The EPA proposes to implement the necessary emissions reductions as follows. The proposed FIP requirements establish ozone season NO_X emissions budgets for EGUs in 25 states (Alabama, Arkansas, Delaware, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Tennessee, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming) and require EGUs in these states to participate in a revised version of the Cross-State Air Pollution Rule (CSAPR) NO_X Ozone Season Group 3 Trading Program that was previously established in the Revised CSAPR Update.[3] The EPA proposes to amend existing FIPs for 12 states currently participating in the CSAPR NO_X Ozone Season Group 3 Trading Program (Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, New Jersey, New York, Ohio, Pennsylvania, Virginia, and West Virginia) to replace their existing emissions budgets established in the Revised CSAPR Update (with respect to the 2008 ozone NAAQS) with new

[1] *See* 80 FR 65291 (October 26, 2015).

[2] In general, specific tribal names or reservations are not identified separately in this proposal except as needed. See Section IV.C.2 of this notice for further discussion.

[3] As explained in Section VI.C.1 of this notice, EPA proposes finding that EGU sources within the State of California are sufficiently controlled such that no further emissions reductions are needed from them to eliminate significant contribution to downwind states.

emissions budgets. For eight states currently covered by the CSAPR NO_X Ozone Season Group 2 Trading Program under SIPs or FIPs, the EPA is proposing to issue new FIPs for two states (Alabama and Missouri) and amend existing FIPs for six states (Arkansas, Mississippi, Oklahoma, Tennessee, Texas, and Wisconsin) to transition EGU sources in these states from the Group 2 program to the revised Group 3 trading program, beginning with the 2023 ozone season. EPA proposes to issue new FIPs for five states not currently covered by any CSAPR NO_X ozone season trading program: Delaware, Minnesota, Nevada, Utah, and Wyoming.

Under this proposed rulemaking, emissions reductions in the selected control stringency would be achieved as soon as they are available, some of which are scheduled to occur by the 2023 ozone season and prior to the August 3, 2024, attainment date for areas classified as Moderate nonattainment for the 2015 ozone NAAQS, and the rest of which occur as soon as possible thereafter through the 2026 ozone season, prior to the August 3, 2027, attainment date for areas classified as Serious nonattainment for the 2015 ozone NAAQS. As discussed in Section VII.A.2 of this notice, the EPA proposes to find that the 2026 ozone season is as expeditious as practicable to implement substantial emissions reductions from potential new post-combustion control installations at EGUs as well as from installation of new pollution controls at non-EGUs.

These EGU emissions reductions are scheduled to begin in the 2026 ozone season based on the feasibility of control installation for EGUs in 22 states that remain linked to downwind nonattainment and maintenance receptors in that year. These 22 states are: Arkansas, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming. The additional emissions reductions required for these states are based primarily on the potential retrofit of additional post-combustion controls for NO_X on most coal steam EGUs and a portion of oil/gas steam EGUs that are currently lacking such controls.

In this proposed rule, the EPA introduces additional features to the allowance-based trading program approach for EGUs, including dynamic adjustments of the emissions budgets over time and backstop daily emissions rate limits for most coal-fired units, that will help maintain control stringency over time and improve emissions performance at individual units, providing further assurance that existing pollution controls will be operated during the ozone season and that the emission reductions necessary to meet good neighbor requirements will be achieved.

The EPA proposes to find that NO_X emissions from non-EGU sources are significantly contributing to nonattainment or interfering with maintenance of the 2015 ozone NAAQS and that cost-effective controls for NO_X emissions reductions are available in certain industrial source categories that would result in meaningful air quality improvements in downwind receptors. The EPA proposes to require emissions limitations beginning in 2026 for non-EGUs located within 23 states: Arkansas, California, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming. The proposed rule establishes NO_X emissions limitations during the ozone season for the following unit types for sources in non-EGU industries: Reciprocating internal combustion in Pipeline Transportation of Natural Gas sources; kilns in Cement and Cement Product Manufacturing sources; boilers and furnaces in Iron and Steel Mills and Ferroalloy Manufacturing sources; furnaces in Glass and Glass Product Manufacturing sources; and high-emitting equipment and large boilers in Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mills.

A. Purpose of the Regulatory Action

The purpose of this rulemaking is to protect public health and the environment by reducing interstate transport of certain air pollutants that significantly contribute to nonattainment, or interfere with maintenance, of the 2015 ozone NAAQS in other states. Ground-level ozone has detrimental effects on human health as well as vegetation and ecosystems. Acute and chronic exposure to ozone in humans is associated with premature mortality and a number of morbidity effects, such as asthma exacerbation. Ozone exposure can also negatively impact ecosystems by limiting tree growth, causing foliar injury, and changing ecosystem community composition. Section IV of this proposed rule provides additional evidence of the harmful effects of ozone exposure on human health and the environment. Studies have established that ozone air pollution can be transported over hundreds of miles, with elevated ground-level ozone concentrations occurring in rural and metropolitan areas.[4 5] Assessments of ozone control approaches have concluded that control strategies targeting reduction of NO_X emissions are an effective method to reduce regional-scale ozone transport.[6]

CAA section 110(a)(2)(D)(i)(I) requires states to prohibit emissions that will contribute significantly to nonattainment or interfere with maintenance in any other state with respect to any primary or secondary NAAQS.[7] States fulfill their primary responsibility to address interstate transport emissions under the good neighbor provision by submitting SIPs containing enforceable emission limitations and other control measures, means, or techniques required to address the interstate transport provision. Within 3 years of the EPA promulgating a new or revised NAAQS, states are required to provide infrastructure SIP submittals, including good neighbor SIPs. *See* CAA section 110(a)(1) and (2). When states do not submit approvable interstate transport SIPs or fail to submit interstate transport SIPs by the statutory deadline, the CAA requires the EPA to issue FIPs to ensure that states eliminate their significant contribution to downwind air quality problems under the good neighbor provision. *See generally* CAA section 110(k) and 110(c). As such, in this proposed rule, the EPA is proposing requirements to fully address good neighbor obligations for these states for the 2015 ozone NAAQS under its authority to promulgate FIPs under CAA section 110(c).

It is appropriate to issue this proposal at this time for at least three reasons. First, this proposal will ensure that necessary emissions reductions to eliminate significant contribution are achieved as expeditiously as practicable. The EPA's anticipated timing will provide for all possible emissions reductions to go into effect

[7] 42 U.S.C. 7410(a)(2)(D)(i)(I).

beginning in the 2023 ozone season, which is aligned with the next upcoming attainment date of August 3, 2024, for areas classified as Moderate nonattainment under the 2015 ozone standard. Additional emissions reductions that the EPA finds not possible to implement by that attainment date are proposed to take effect as expeditiously as practicable, with the full suite of emissions reductions taking effect by the 2026 ozone season, which is aligned with the August 3, 2027, attainment date for areas classified as Serious nonattainment under the 2015 ozone NAAQS. As explained in sections V.A, VI, and VII.A of this proposed rule, these proposed timeframes for eliminating significant contribution are consistent with the provisions of title I of the CAA. Second, this proposal will provide states with as much information as the EPA can supply at this time to support their ability to submit SIP revisions to achieve the emissions reductions the EPA believes necessary to eliminate significant contribution. Third, for all of the states included in this proposed rule, the EPA's modeling and analysis indicate that additional emissions reductions beyond those which are provided in any state's 2015 ozone transport SIP are necessary to eliminate significant contribution.

The EPA anticipates that the states covered in this proposed FIP rulemaking may not have adequate provisions in their SIPs to address their interstate transport obligations for the 2015 ozone NAAQS. As discussed in Section IV.B.2 of this proposed rule, the EPA has, for certain states, made findings that the state failed to submit a complete good neighbor SIP revision for the 2015 ozone NAAQS. For certain other states, the EPA has proposed, but has not finalized, actions disapproving good neighbor SIP revisions. And for other states, the EPA has not yet proposed action on their good neighbor SIP submittals, but these submittals are currently under review, and EPA intends to act on these submittals in the coming months. The EPA will not finalize this proposed FIP action for any state for which it has not taken final action either disapproving that state's good neighbor SIP submittal or finding that the state failed to submit a complete SIP.

The EPA conducted air quality modeling for future analytic years to identify (1) the downwind areas that are expected to have trouble attaining or maintaining the 2015 ozone NAAQS in the future and (2) the contribution of ozone transport from upwind states to the downwind air quality problems. Section V of this proposed rule provides a full description of the results of EPA's air quality modeling and relevant analyses for the proposed rulemaking. Based on EPA's air quality analysis, a total of 27 upwind states are linked above the 1 percent of the NAAQS threshold to downwind air quality problems in other states. The EPA had previously approved 2015 ozone transport SIPs submitted by two of these states—Oregon and Delaware—and proposes in this proposed rule to issue an error correction for its prior approval of Delaware's 2015 ozone transport SIP (*see* Section IV.C.1 of this notice for additional information on the proposed error correction). The EPA is not proposing any change to its prior approval of Oregon's 2015 ozone transport SIP, a determination which is further described in Section V.F of this proposed rule.

In this proposed rule, the EPA is proposing to issue FIP requirements for 26 states, which include emissions reductions for EGU sources within the borders of 25 states (described in Section VII.B of this proposed rule) and include emissions reductions for non-EGU sources within the borders of 23 states (described in Section VII.C in this proposed rule). Based on EPA's assessment of remaining air quality issues and additional emissions control strategies, the EPA further proposes to find that the EGU and non-EGU NO_X emissions reductions required in the proposed rule would fully eliminate these states' significant contributions to downwind air quality problems for the 2015 ozone NAAQS. By eliminating significant contribution from these upwind states, this rule, if finalized as proposed, will make substantial and meaningful improvements in air quality by reducing ozone levels at the identified downwind receptors as well as many other areas of the country.

1. Emissions Limitations for EGUs Established by the Proposed Rule

In this proposed rule, the EPA proposes to issue FIP requirements that include new NO_X ozone season emissions budgets for EGU sources within the borders of the 25 states listed in Table I.A–1, with implementation of these emissions budgets beginning in the 2023 ozone season. The EPA proposes to find that these emissions reductions are necessary to address upwind states' interstate transport obligations for the 2015 ozone NAAQS.

The EPA proposes to expand the CSAPR NO_X Ozone Season Group 3 Trading Program beginning in the 2023 ozone season. Specifically, the FIPs would require power plants within the borders of the 25 states listed in Table I.A–1 to participate in a revised version of the CSAPR NO_X Ozone Season Group 3 Trading Program created by the Revised CSAPR Update. Affected EGUs within the borders of twelve states currently participating in the Group 3 Trading Program under FIPs or SIPs would remain in the program, with revised provisions beginning in the 2023 ozone season, under this proposed rule: Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, New Jersey, New York, Ohio, Pennsylvania, Virginia, and West Virginia. The FIPs would also require affected EGUs within the borders of eight states currently covered by the CSAPR NO_X Ozone Season Group 2 Trading Program (the ''Group 2 trading program'') under existing FIPs or existing SIPs to transition from the Group 2 program to the revised Group 3 trading program beginning with the 2023 control period: (Alabama, Arkansas, Mississippi, Missouri, Oklahoma, Tennessee, Texas, and Wisconsin).[8] Finally, the EPA is

[8] Six of these eight states (Arkansas, Mississippi, Oklahoma, Tennessee, Texas, and Wisconsin) currently participate in the federal Group 2 trading program pursuant to the FIPs finalized in the CSAPR Update, so the FIPs proposed in this rulemaking would amend the existing FIPs for these

proposing to issue new FIPs for EGUs within the borders of five states not currently covered by any CSAPR trading program for seasonal NO_X emissions: Delaware, Minnesota, Nevada, Utah, and Wyoming. If the proposed FIP is finalized, sources in these states would enter the Group 3 trading program in the 2023 control period following the effective date of the final rule.[9] In all cases, if the state submits and the EPA approves a SIP revision that would fully achieve the emissions reductions needed to meet the state's good neighbor obligations with respect to the 2015 ozone NAAQS before a final rule is promulgated in this rulemaking, the proposed FIP requirements summarized above would not be finalized. Refer to Section VII.B of this proposed rule for details on EGU regulatory requirements.

2. Emissions Limitations for Non-EGU Stationary Point Sources Established by the Proposed Rule

In this proposed rule, the EPA proposes to issue FIP requirements that include new NO_X emissions limitations for non-Electric Generating Unit (non-EGU) sources in 23 states, with earliest possible compliance dates for these emissions limitations beginning in 2026. The EPA proposes to require emissions reductions from non-EGU sources to address interstate transport obligations for the 2015 ozone NAAQS for the 23 states listed in Table I.A–2.

states. The other two states (Alabama and Missouri) have already replaced the FIPs finalized in the CSAPR Update with approved SIP revisions that require their EGUs to participate in state Group 2 trading programs integrated with the federal Group 2 trading program, so the FIPs proposed in this action would constitute new FIPs for these states, and the EPA would cease implementation of the state Group 2 trading programs included in the two states' SIPs.

[9] Two states, Kansas and Iowa, will remain in the Group 2 Trading Program.

The EPA is proposing to require emissions limitations for the following unit types in non-EGU industries: Reciprocating internal combustion engines in Pipeline Transportation of Natural Gas sources; kilns in Cement and Cement Product Manufacturing sources; boilers and furnaces in Iron and Steel Mills and Ferroalloy Manufacturing sources; furnaces in Glass and Glass Product Manufacturing sources; and high-emitting equipment and large boilers in Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mills. Refer to Table III.A–1 for a list of North American Industry Classification System (NAICS) codes for each entity included for regulation under this proposed rule.

3. Proposed Error Correction for Previously Approved 2015 Ozone Transport SIP

The EPA proposes to make an error correction under CAA section 110(k)(6) of its May 1, 2020, approval at 85 FR 25307 of the interstate transport elements for Delaware's October 11, 2018, and December 26, 2019, ozone infrastructure SIP submissions as satisfying the requirements of CAA section 110(a)(2)(D)(i)(I) for the 2015 ozone NAAQS. The EPA proposes to determine that the basis for the prior SIP approval is invalidated by the Agency's more recent technical evaluation of air quality modeling performed in support of the proposed rule,[10] and that Delaware has unresolved interstate transport obligations for the 2015 ozone NAAQS. In this proposed rule, the EPA is also exercising its authority to propose to issue a FIP for Delaware in light of these unresolved interstate transport obligations.

[10] *See* the Air Quality Modeling Technical Support Document (AQM TSD) in the docket for this proposed rule.

4. Request for Comment on All Aspects of the Proposal

Throughout this proposed rule, unless noted otherwise, the EPA is requesting comments on all aspects of the proposal to enable the Agency to develop a final rule that, consistent with our responsibilities under section 110 of the CAA, eliminates air pollution that significantly contributes to nonattainment or interference with maintenance of the 2015 ozone NAAQS. This proposed rule adheres closely to the legal and analytical framework that the EPA has applied in the past in implementing the good neighbor provision of the CAA, as well as the ample case law reviewing that framework. At the same time, in this proposal, the EPA is applying lessons learned from the performance of regulatory programs established by previous ozone transport rulemakings, as well as updating the Agency's application of the 4-step interstate transport framework with recent information on the nature of ozone transport and emissions reductions opportunities in order to eliminate significant contribution for the more stringent 2015 ozone NAAQS under the good neighbor provision. The EPA invites comments and information to support its efforts to improve the regulation of interstate ozone transport under the good neighbor provision and to fulfill our mission to protect human health and the environment. The EPA will carefully consider information provided in response to this request and will respond to comments submitted through the regulatory docket in the final rule.

B. Summary of the Major Provisions of the Regulatory Action

The EPA is applying the 4-step interstate transport framework developed in CSAPR, the CSAPR Update, the Revised CSAPR Update, and other previous ozone transport rules to propose to further limit NO_X emissions from EGU sources within the borders of 25 states during the ozone season (May 1 through September 30) and to limit ozone season NO_X emissions from non-EGU sources in 23 states to reduce interstate ozone transport under the authority provided in CAA section 110(a)(2)(D)(i)(I). The 4-step interstate transport framework provides a stepwise method for the EPA to propose rule provisions that are required to address the requirements of the good neighbor provision for the 2015 ozone NAAQS: (1) Identifying downwind receptors that are expected to have problems attaining or maintaining the NAAQS; (2) determining which upwind states contribute to these identified problems in amounts sufficient to ''link'' them to the downwind air quality problems (*i.e.,* in this proposed rule, a contribution threshold of 1 percent of the NAAQS); (3) for states linked to downwind air quality problems, identifying upwind emissions that significantly contribute to downwind nonattainment or interfere with downwind maintenance of the NAAQS; and (4) for states that are found to have emissions that significantly contribute to nonattainment or interfere with maintenance of the NAAQS in downwind areas, implementing the necessary emissions reductions through enforceable measures. In this proposed rule, the EPA applies the 4-step framework to evaluate upwind states' obligations to reduce interstate transport of ozone precursor emissions for the 2015 ozone NAAQS. The remainder of this section provides a general overview of the EPA's application of the 4-step framework as it applies to major provisions of the proposed rule; additional details regarding EPA's proposed rule approach are found in Section IV of this proposed rule.

In order to apply the first step of the 4-step framework to the 2015 ozone NAAQS, the EPA performed air quality modeling to project ozone concentrations at air quality monitoring sites in 2023, 2026, and 2032.[11] The EPA evaluated projected ozone concentrations for the 2023 analytic year at individual monitoring sites and considered current ozone monitoring data at these sites to identify receptors that are anticipated to have problems attaining or maintaining the 2015 ozone NAAQS. This analysis was then repeated using projected ozone concentrations for 2026 and 2032.

To apply the second step of the framework, the EPA used air quality modeling to quantify the contributions from upwind states to ozone concentrations in 2023 and 2026 at downwind receptors.[12] Once quantified, EPA then evaluated these contributions relative to a screening threshold of 1 percent of the NAAQS (*i.e.,* 0.70 ppb).[13] States with contributions that equaled or exceeded 1 percent of the NAAQS were identified as warranting further analysis at Step 3 of the four-step framework to determine if the upwind state significantly contributes to nonattainment or interference with maintenance in a downwind state. States with contributions below 1 percent of the NAAQS were considered not to significantly contribute to nonattainment or interfere with maintenance of the NAAQS in downwind states. Based on EPA's most recent air quality modeling and contribution analysis using 2023 as the analytic year, the EPA proposes to find that the following 27 states have contributions that equal or exceed 1 percent of the 2015 ozone NAAQS, and, thereby, warrant further analysis of significant contribution to nonattainment or interference with maintenance of the NAAQS: Alabama, Arkansas, California, Delaware, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Oregon, Pennsylvania, Tennessee, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming. Further evaluation of the locations in California to which Oregon was linked at Step 2 leads the EPA to conclude downwind areas represented by these monitoring sites should not be considered interstate ozone transport receptors. Therefore, the EPA is not proposing any further emissions reductions from the state of Oregon because there is no significant contribution required to be eliminated under the interstate transport provision, as described in Section V.F of this proposed rule.

Based on the air quality analysis presented in Section V of this proposed rule, the EPA proposes to find that in the absence of additional emissions reductions in those states the majority of the states that the EPA is proposing to participate in the Ozone Season Group 3 Trading Program will continue to contribute above the 1 percent of the NAAQS threshold to at least one receptor whose nonattainment and maintenance concerns persist through the 2026 ozone season, with the exception of Alabama, Delaware, and Tennessee. As a result, EPA's evaluation of emissions reduction potential at Step 3 for Alabama, Delaware, and Tennessee is limited to emission reductions achievable by the 2023 ozone season. For each of these three states, EPA's analysis does not consider, nor does the EPA propose to require, emissions reductions at either EGUs or non-EGUs that cannot be implemented until the 2026 ozone season.

At the third step of the 4-step framework, EPA applied a multi-factor test that incorporates cost, availability of emissions reductions, and air quality impacts at the downwind receptors to determine the amount of ozone precursor emissions from the linked upwind states that ''significantly'' contribute to downwind nonattainment or maintenance receptors. In this proposed rule, the EPA proposes to apply the multifactor test described in Section VI.A of this proposed rule to both EGU and non-EGU sources. The EPA assessed the potential emissions reductions in 2023 and 2026, as well as in intervening and later years to determine the emissions reductions required to eliminate significant contribution in any future year where downwind areas are projected to have potential problems attaining or maintaining the 2015 ozone NAAQS.

For EGU sources, the EPA evaluated the following set of widely-available NO_X emissions control technologies: (1) Fully operating existing selective catalytic reduction (SCR) controls, including both optimizing NO_X removal by existing operational SCRs and turning on and optimizing existing idled SCRs; (2) installing state-of-the-art NO_X combustion controls; (3) fully operating existing selective non-catalytic reduction (SNCR) controls, including both optimizing NO_X removal by existing operational SNCRs and turning on and optimizing existing idled SNCRs; (4) installing new SNCRs; (5) installing new SCRs; and (6) generation shifting. For the reasons explained in Section VI of this proposed rule and supported by the EGU NO_X Mitigation Strategies Proposed Rule Technical Support Document (TSD) included in the docket for this proposed rule, the EPA determined that for the regional, multi-state scale of this rulemaking, only fully operating and optimizing existing SCRs and existing SNCRs (EGU NO_X emissions controls options 1 and 3 in the list earlier) are possible for the 2023 ozone season. The EPA determined that state-of-the-art NO_X combustion controls at EGUs (emissions control option 2 in the list above) are available by the beginning of the 2024 ozone season. Based on EPA's assessment of the earliest possible timeframe for installation of new SNCR and SCRs (EGU emissions controls options 4 and 5 in the list), the EPA proposes to require emissions reductions commensurate with these controls by the beginning of the 2026 ozone season. *See* Section VI.B.1 of this proposed rule for a full description of

[11] These 3 analytic years are the last full ozone seasons before, and thus align with, upcoming attainment dates for the 2015 ozone NAAQS: August 3, 2024, for areas classified as Moderate nonattainment, August 3, 2027, for areas classified as Serious nonattainment, and August 3, 2033, for areas classified as Severe. *See* 83 FR 25776.

[12] The EPA did not perform contribution modeling for 2032 since contribution data for this year were not needed to identify upwind states to be analyzed in Step 3.

[13] *See* Section V of this proposed rule for explanation of EPA's use of the 1 percent of the NAAQS threshold in the Step 2 analysis.

EPA's analysis of NO_X emissions mitigation strategies for EGU sources.

The EPA proposes control stringency levels that maximize incremental NO_X emissions reduction potential from EGUs and corresponding downwind ozone air quality improvements to the extent feasible in each year analyzed. The EPA believes that the required controls provide cost-effective reductions of NO_X emissions that will provide substantial improvements in downwind ozone air quality to address interstate transport obligations for the 2015 ozone NAAQS in a timely manner. These controls represent greater stringency in upwind EGU controls than in EPA's most recent ozone transport rulemakings, such as the CSAPR Update and the Revised CSAPR Update. However, programs to address interstate ozone transport based on the retrofit of post-combustion controls are by no means unprecedented. In prior ozone transport rulemakings such as the NO_X SIP Call and the Clean Air Interstate Rule (CAIR), the EPA established EGU budgets premised on the widespread availability of retrofitting EGUs with post-combustion emissions controls such as SCR.[14] While these programs successfully drove many EGUs to retrofit post-combustion controls, other EGUs throughout the present geography of linked upwind states continue to operate without such controls and continue to emit at relatively high rates more than 20 years after similar units reduced these emissions under prior interstate ozone transport rulemakings.

Furthermore, the CSAPR Update provided only a partial remedy for eliminating significant contribution for the 2008 ozone NAAQS, as needed to obtain available reductions by the 2017 ozone season. In that rule, the EPA made no determination regarding the appropriateness of more stringent EGU NO_X controls that would be required for a *full* remedy for interstate transport for the 2008 ozone NAAQS. Following the remand of the CSAPR Update in *Wisconsin* v. *EPA,* 938 F.3d 303 (D.C. Cir. 2019) (*Wisconsin*), the EPA again declined to require the retrofit of new post-combustion controls on EGUs in the Revised CSAPR Update, but that determination was based on a specific timing consideration: Downwind air quality problems under the 2008 ozone NAAQS were projected to resolve before post-combustion control retrofits could be accomplished on a fleetwide, regional scale. *See* 86 FR 23054, 23110 (April 30, 2021).

In this proposed rulemaking, the EPA is addressing good neighbor obligations for the more stringent 2015 ozone NAAQS, and the Agency observes ongoing and persistent contribution from upwind states to ozone nonattainment and maintenance receptors in other states under that NAAQS. As further discussed in Section VI of this proposed rule, the nature of this contribution warrants a greater degree of control stringency than the EPA determined to be necessary to eliminate significant contribution of ozone transport in prior CSAPR rulemakings. The EPA is therefore returning to EGU NO_X control strategies commensurate with those determined to be necessary in the NO_X SIP Call and CAIR.

Based on the Step 3 analysis described in Section VI of this proposed rule, the EPA is proposing that emissions reductions commensurate with the full operation of all existing post-combustion controls (both SCRs and SNCRs) and state-of-the-art combustion control upgrades constitute the Agency's selected control stringency for EGUs within the borders of 25 states linked to downwind nonattainment or maintenance in 2023 (Alabama, Arkansas, Delaware, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Tennessee, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming). For 22 of those states that are also linked in 2026 (Arkansas, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming), the EPA is determining that the selected EGU control stringency also includes emissions reductions commensurate with the retrofit of SCR at coal steam units of 100 MW or greater capacity (excepting circulating fluidized bed units (CFB)), new SNCR on coal steam units of less than 100 MW capacity and CFBs, and SCR on oil/gas steam units greater than 100 MW that have historically emitted at least 150 tons of NO_X per ozone season.

To identify appropriate control strategies for non-EGU sources to achieve NO_X emissions reductions that would result in meaningful air quality improvements in downwind areas, the EPA developed an analytical framework to evaluate the air quality impacts of potential emissions reductions from non-EGU sources located in the linked upwind states. The EPA incorporated air quality modeling information, annual emissions, and information about potential controls to determine which industries, if subject to further control requirements, would have the greatest impact in providing air quality improvements at the downwind receptors. This evaluation was subject to a marginal cost threshold of up to $7,500 per ton, which the EPA determined based on information available to the Agency about existing control device efficiency and cost information. Additional information on the analytical framework is described in Section VI.B.2 of this proposed rule and is presented in the memorandum titled *Screening Assessment of Potential Emissions Reductions, Air Quality Impacts, and Costs from Non-EGU Emissions Units for 2026* (''Non-EGU Screening Assessment memorandum''), which is available in the docket for this proposed rulemaking. Based on the results of this assessment, the EPA identified emissions unit types in seven industries (identified in Section I.A.2 of this proposed rule) that provide opportunities for NO_X emissions reductions that result in meaningful impacts on air quality at the downwind receptors.

The EPA performed air quality analysis using the Ozone Air Quality Assessment Tool (AQAT) to determine whether the proposed emissions reductions for both EGUs and non-EGUs potentially create an ''over-control'' scenario whereby (1) the expected ozone improvements would be greater than necessary to resolve the downwind ozone pollution problem (*i.e.,* beyond what is necessary to resolve all nonattainment and maintenance problems to which an upwind state is linked) or (2) the expected ozone improvements would reduce the upwind state's ozone contributions below the screening threshold (*i.e.,* 1 percent of the NAAQS or 0.70 ppb). The EPA's over-control analysis, discussed in Section VI.D.4 of this proposed rule, shows that the proposed control stringencies for EGU and non-EGU sources do not over-control upwind states' emissions either with respect to the downwind air quality problems to which they are linked or with respect to the 1 percent of the NAAQS contribution threshold, such that over-control would trigger re-evaluation at Step 3 for any linked upwind state.

[14] *See, e.g.,* 70 FR 25162, 25205–06 (May 12, 2005).

Based on the multi-factor test applied to both EGU and non-EGU sources and our subsequent assessment of over-control, the EPA finds that the selected EGU and non-EGU control stringencies constitute the elimination of significant contribution and interference with maintenance, without over-controlling emissions, from the 26 upwind states subject to EGU and non-EGU emissions reductions requirements under the proposed rule. In order to eliminate significant contribution and interference with maintenance through the fourth step of the 4-step framework, as described in Section VII of this proposed rule, the EPA is establishing emissions budgets for EGUs within the borders of 25 states that reflect the remaining allowable emissions after the emissions reductions associated with the selected control stringency have been achieved. For the same reason, the EPA is establishing non-EGU emissions limits in 23 states that result in the elimination of significant contribution from non-EGU sources in these states. For additional details about the test and the over-control analysis, *see* the document titled, ''Ozone Transport Policy Analysis Proposed Rule TSD'' included in the docket for this rulemaking.

In this fourth step of the 4-step framework, the EPA proposes to include enforceable measures in the promulgated FIPs to achieve the required emissions reductions in each of the 26 states. Specifically, the FIPs would require covered power plants within the borders of the 25 states listed in Table I.A–1 to participate in the CSAPR NO_X Ozone Season Group 3 Trading Program created by the Revised CSAPR Update. Affected EGUs within the borders of twelve states currently participating in the Group 3 Trading Program would remain in the program, with revised provisions beginning in the 2023 ozone season, under this proposed rule: Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, New Jersey, New York, Ohio, Pennsylvania, Virginia, and West Virginia. Affected EGUs within the borders of eight states currently covered by the CSAPR NO_X Ozone Season Group 2 Trading Program (the ''Group 2 trading program'')—Alabama, Arkansas, Mississippi, Missouri, Oklahoma, Tennessee, Texas, and Wisconsin—would transition from the Group 2 program to the revised Group 3 trading program beginning with the 2023 control period,[15] and affected EGUs within the borders of five states not currently covered by any CSAPR trading program for seasonal NO_X emissions—Delaware, Minnesota, Nevada, Utah, and Wyoming—would enter the Group 3 trading program in the 2023 control period following the effective date of the final rule. In addition, the EPA proposes to revise other aspects of the Group 3 trading program to help maintain control stringency over time and improve emissions performance at individual units, offering a necessary measure of assurance that existing pollution controls will be operated during the ozone season, as described in Section VII of this proposed rule. This proposal does not revise the budget stringency and geography of the existing CSAPR NO_X Ozone Season Group 1 trading program. Aside from the eight states moving from the Group 2 trading program to the Group 3 trading program under the proposed rule, this proposal otherwise leaves unchanged the budget stringency of the existing CSAPR NO_X Ozone Season Group 2 trading program.

The EPA is proposing preset ozone season NO_X emissions budgets for the 2023 and 2024 ozone seasons, as explained in Section VII.B of this proposed rule and as shown in Table I.B–1.

TABLE I.B–1—PROPOSED AND ILLUSTRATIVE CSAPR NO_X OZONE SEASON GROUP 3 STATE EMISSIONS BUDGETS FOR 2023 THROUGH 2026 CONTROL PERIODS *

State	Proposed emissions budgets for 2023 control period (tons)	Proposed emissions budgets for 2024 control period (tons)	Illustrative emissions budgets for 2025 control period (tons)	Illustrative emissions budgets for 2026 control period (tons)
Alabama	6,364	6,306	6,306	6,306
Arkansas	8,889	8,889	8,889	3,923
Delaware	384	434	434	434
Illinois	7,364	7,463	7,463	6,115
Indiana	11,151	9,391	8,714	7,791
Kentucky	11,640	11,640	11,134	7,573
Louisiana	9,312	9,312	9,179	3,752
Maryland	1,187	1,187	1,187	1,189
Michigan	10,718	10,718	10,759	6,114
Minnesota	3,921	3,921	3,910	2,536
Mississippi	5,024	4,400	4,400	1,914
Missouri	11,857	11,857	10,456	7,246
Nevada	2,280	2,372	2,372	1,211
New Jersey	799	799	799	799
New York	3,763	3,763	3,763	3,238
Ohio	8,369	8,369	8,369	8,586
Oklahoma	10,265	9,573	9,393	4,275
Pennsylvania	8,855	8,855	8,855	6,819
Tennessee	4,234	4,234	4,008	4,008
Texas	38,284	38,284	36,619	21,946
Utah	14,981	15,146	15,146	2,620
Virginia	3,090	2,814	2,948	2,567
West Virginia	12,478	12,478	12,478	10,597
Wisconsin	5,963	5,057	4,198	3,473

[15] The EPA would deem participation in the Group 3 trading program by the EGUs in these eight states as also addressing the respective states' good neighbor obligations with respect to the 2008 ozone NAAQS (for all eight states), the 1997 ozone NAAQS (for all the states except Texas), and the 1979 ozone NAAQS (for Alabama, Missouri, and Tennessee) to the same extent that those obligations are currently being addressed by participation of the states' EGUs in the Group 2 trading program.

TABLE I.B–1—PROPOSED AND ILLUSTRATIVE CSAPR NO_X OZONE SEASON GROUP 3 STATE EMISSIONS BUDGETS FOR 2023 THROUGH 2026 CONTROL PERIODS *—Continued

State	Proposed emissions budgets for 2023 control period (tons)	Proposed emissions budgets for 2024 control period (tons)	Illustrative emissions budgets for 2025 control period (tons)	Illustrative emissions budgets for 2026 control period (tons)
Wyoming	9,125	8,573	8,573	4,490

* Further information on the state-level emissions budget calculations pertaining to Table I.B–1 is provided in Section VII.B.4 of this proposed rule as well as the Ozone Transport Policy Analysis Proposed Rule TSD. Further information on the proposed approach for allocating a portion of Utah's emissions budget for each control period to the existing EGU in the Uintah and Ouray Reservation within Utah's borders is provided in Section VII.B.9 of this proposed rule.

Beyond preset emissions budgets for the 2023 and 2024 control periods, the EPA also proposes to extend the Group 3 trading program budget-setting methodology used in the Revised CSAPR Update so as to routinely set emissions budgets for each future control period (beginning in 2025) in the year before that control period, with each emissions budget reflecting the latest available information on the composition and utilization of the EGU fleet at the time that emissions budget is determined (*see* Table VII.B.4.c–2 for illustrative examples of dynamic budget calculations that the EPA will publish in advance of each ozone season, effective for the 2025 control period and beyond). The stringency of the dynamic emissions budgets would simply reflect the stringency of the emissions control strategies selected in the rulemaking more consistently over time and ensure that the annual updates would eliminate emissions determined to be unlawful under the good neighbor provision. *See* Section VII.B of this proposed rule for additional discussion of EPA's proposed method for adjusting emissions budgets to ensure elimination of significant contribution from EGU sources in the linked upwind states.

As an enhancement to the structure of the trading program as originally promulgated in the Revised CSAPR Update, the EPA is also proposing to establish backstop daily emissions rates for coal steam units greater than or equal to 100 MW in covered states. Units emitting in excess of these daily rates would be subject to increased allowance surrender requirements under the trading program. The backstop daily emissions rates would work in tandem with the ozone season emissions budgets to offer downwind stakeholders a necessary measure of assurance that they will be protected on a daily basis during the ozone season by continuous operation of installed pollution controls. The EPA's experience with the CSAPR trading programs has revealed instances where EGUs have reduced their SCRs' performance on a given day, or across the entire ozone seasons in some cases, including high ozone days.[16] In addition to maintaining a mass-based seasonal requirement, the EPA proposes to require controls while maintaining as much compliance flexibility as possible through a unit-level emission rate designed to ensure that controls operate continuously and that required reductions occur on the highest ozone days. These trading program improvements also promote consistent emissions control performance across the power sector, which protects communities living in downwind ozone nonattainment areas from exceedances of the NAAQS that might otherwise occur.

The EPA proposes to include enforceable emissions standards that will apply during the ozone season (annually from May to September) for seven non-EGU industries in the promulgated FIPs to achieve the required emissions reductions in 23 states with remaining interstate transport obligations for the 2015 ozone NAAQS in 2026: Arkansas, California, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming. These requirements would apply to all existing emissions units and to any future emissions units constructed in the covered states after promulgation of the final rule. Thus, the emissions limits for non-EGU sources and associated compliance requirements would apply in all 23 states listed in this paragraph, even if certain of these states do not currently have existing emissions units within a particular industry.

Based on our evaluation of the time required to install controls at the types of non-EGU sources covered by this proposed rule, the EPA has identified the 2026 ozone season as the earliest compliance date possible for non-EGU emissions reductions. The EPA is therefore proposing to include non-EGU emissions reductions beginning in 2026. For sources located in the 23 states listed in the previous paragraph, The EPA proposes to require the emissions limits listed in Table I.B–2 for

[16] *See* 86 FR 23090. The EPA highlighted the Miami Fort Unit 7 (possessing a SCR) more than tripled its ozone-season NO_X emission rate between 2017 and 2019.

reciprocating internal combustion engines in Pipeline Transportation of Natural Gas; the emissions limits listed in Table I.B–3 for kilns in Cement and Cement Product Manufacturing; the emissions limits listed in Table I.B–4 for boilers and furnaces in Iron and Steel Mills and Ferroalloy Manufacturing; the emissions limits listed in Table I.B–5 for furnaces in Glass and Glass Product Manufacturing; and the emissions limits listed in Table I.B–6 for high-emitting equipment and large boilers in Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mills.

TABLE I.B–2—SUMMARY OF PROPOSED NO_X EMISSIONS LIMITS FOR PIPELINE TRANSPORTATION OF NATURAL GAS

Engine type and fuel	Proposed NO_X emissions limit
Natural Gas Fired Four Stroke Rich Burn.	1.0 g/hp-hr.
Natural Gas Fired Four Stroke Lean Burn.	1.5 g/hp-hr.
Natural Gas Fired Two Stroke Lean Burn.	3.0 g/hp-hr.

TABLE I.B–3—SUMMARY OF PROPOSED NO_X EMISSIONS LIMITS FOR KILN TYPES IN CEMENT AND CONCRETE PRODUCT MANUFACTURING

Kiln type	Proposed NO_X emissions limit (lb/ton of clinker)
Long Wet	4.0
Long Dry	3.0
Preheater	3.8
Precalciner	2.3
Preheater/Precalciner	2.8

The EPA is also proposing a source cap limit expressed in ton per day (tpd) of NO_X for each individual cement plant according to the following equation.[17]

$$CAP2015\,Ozone\,Transport = \frac{(KW\ x\ NW) + (KD\ x\ ND)}{(2000\frac{pounds}{ton}\ x\ 365\frac{days}{year})}$$

Where:

CAP2015 Ozone Transport = total allowable NO_X emissions from all cement kilns located at one cement plant, in tons per day, on a 30-operating day rolling average basis;

KD = 1.7 pounds NO_X per ton of clinker for dry preheater-precalciner or precalciner kilns;

KW = 3.4 pounds NO_X per ton of clinker for long wet kilns;

ND = the average annual production in tons of clinker plus one standard deviation for the three most recent calendar years from all dry preheater-precalciner or precalciner kilns located at one cement plant; and

NW = the average annual production in tons of clinker plus one standard deviation for the 3 most recent calendar years from all long wet kilns located at one cement plant.

An affected cement plant will need to comply with both the source cap limit and the specific NO_X emissions limits assigned to its individual kiln type(s). Refer to Section VII.C.2 of this proposed rule for additional information concerning the application of the source cap limit to this industry source group.

TABLE I.B–4—SUMMARY OF PROPOSED NO_X EMISSIONS LIMITS FOR IRON AND STEEL AND FERROALLOY EMISSIONS UNITS

Emissions unit	Proposed NO_X emissions standard or requirement (lbs/hour or lb/mmBtu)
Blast Furnace	0.03 lb/mmBtu.
Basic Oxygen Furnace	0.07 lb/ton.
Electric Arc Furnace	0.15 lb/ton steel.
Ladle/tundish Preheaters	0.06 lb/mmBtu.
Reheat furnace	0.05 lb/mmBtu.
Annealing Furnace	0.06 lb/mmBtu.
Vacuum Degasser	0.03 lb/mmBtu.
Ladle Metallurgy Furnace	0.1 lb/ton.
Taconite production kilns	Work practice standard to install low NO_X technology/burners, test and set.
Coke ovens (charging and coking)	0.6 lb/ton of coal charged.
Coke ovens (pushing)	0.015 lb/ton of coal pushed.
Boilers—Coal	0.20 lb/mmBtu.
Boilers—Residual oil	0.20 lb/mmBtu.
Boilers—Distillate oil	0.12 lb/mmBtu.
Boilers—Natural gas	0.08 lb/mmBtu.

[17] Based on source cap equation at 30 TAC § 117.3123(b); January 14, 2009 (74 FR 1927), Docket ID No. EPA–R06–OAR–2007–1147, also *see https://wayback.archive-it.org/414/20210527223433/https://www.tceq.texas.gov/assets/public/legal/rules/rules/pdflib/117e.pdf.*

TABLE IV.B–5—SUMMARY OF PROPOSED NO_X EMISSIONS LIMITS FOR FURNACE UNIT TYPES IN GLASS AND GLASS PRODUCT MANUFACTURING

Furnace type	Proposed NO_X emissions limit (lb/ton of glass produced)
Container Glass Manufacturing Furnace	4.0
Pressed/Blown Glass Manufacturing Furnace or Fiberglass Manufacturing Furnace	4.0
Flat Glass Manufacturing Furnace	9.2

TABLE I.B–6—SUMMARY OF PROPOSED NO_X EMISSIONS LIMITS FOR HIGH-EMITTING EQUIPMENT AND LARGE BOILERS IN BASIC CHEMICAL MANUFACTURING, PETROLEUM AND COAL PRODUCTS MANUFACTURING, AND PULP, PAPER, AND PAPERBOARD MILLS

Unit type	Emissions limit (lbs NO_X/mmBtu)
Coal	0.20
Residual oil	0.20
Distillate oil	0.12
Natural gas	0.08

Refer to Section VII.C of this proposed rule for applicability criteria, compliance assurance requirements, and the EPA's rationale in proposing these emissions limits for each of the non-EGU industries covered by the proposed rule. In addition, the EPA requests comment on several topics regarding the implementation of emissions limits for non-EGU sources that are proposed in this rulemaking, including controls on emissions units and control installation timing. *See* Section VI.D.2.a of this proposed rule for a list of detailed questions on which the Agency is soliciting public comment.

The remainder of this preamble is organized as follows: Section III of this proposed rule outlines general applicability criteria for the proposed rule and describes the EPA's legal authority for this proposed rule, the relationship of the proposed rule to previous interstate ozone transport rulemakings, and the incremental costs and benefits of the proposed rule; Section IV of this proposed rule describes the human health and environmental challenges posed by interstate transport contributions to ozone air quality problems, as well as EPA's overall approach for addressing interstate transport for the 2015 ozone NAAQS in this proposed rule; Section V of this proposed rule describes the Agency's analyses of air quality data to inform this proposed rulemaking, including descriptions of the air quality modeling platform and emissions inventories used in the proposed rule, as well as EPA's methods for identifying downwind air quality problems and upwind states' ozone transport contributions to downwind states; Section VI of this proposed rule describes EPA's approach to quantifying upwind states' obligations in the form of EGU NO_X control stringencies and non-EGU emissions limits; Section VII of this proposed rule describes key elements of the implementation schedule for EGU and non-EGU emissions reductions requirements, including details regarding the revised aspects of the CSAPR NO_X Group 3 trading program and compliance deadlines, as well as regulatory requirements and compliance deadlines for non-EGU sources; Section VIII of this proposed rule discusses the environmental justice considerations of the proposed rule; Section IX of this proposed rule describes the expected costs, benefits, and other impacts of this proposed rule; Section X of this proposed rule provides a summary of proposed changes to the existing regulatory text; and Section XI of this proposed rule discusses the statutory and executive orders affecting this proposed rulemaking.

C. Costs and Benefits

A summary of the key results of the cost-benefit analysis that was prepared for this proposed rule is presented in Table I.C–1. Table I.C–1 presents estimates of the present values (PV) and equivalent annualized values (EAV), calculated using discount rates of 3 and 7 percent as directed by OMB's Circular A–4, of the health benefits, compliance costs, and net benefits of the proposed rule, in 2016 dollars, discounted to 2022. The estimated monetized net benefits are the estimated monetized benefits minus the estimated monetized costs of the proposed rule. These results present an incomplete overview of the effects of the proposal, because important categories of benefits—including benefits from reducing climate pollution, other types of air pollutants, and water pollution—were not monetized and are therefore not reflected in the cost-benefit tables. We anticipate that taking non-monetized effects into account would show the proposal to be more net beneficial than this table reflects.

TABLE I.C–1—ESTIMATED MONETIZED BENEFITS, COMPLIANCE COSTS, AND NET BENEFITS OF THE PROPOSED RULE, 2023 THROUGH 2042

[Millions 2016$, discounted to 2022][a]

	3% Discount rate	7% Discount rate
Present Value:		
Benefits[b]	250,000	150,000
Compliance Costs[c]	22,000	14,000
Net Benefits	220,000	130,000
Equivalent Annualized Value:		
Benefits	17,000	14,000
Compliance Costs	1,500	1,300

TABLE I.C–1—ESTIMATED MONETIZED BENEFITS, COMPLIANCE COSTS, AND NET BENEFITS OF THE PROPOSED RULE, 2023 THROUGH 2042—Continued

[Millions 2016$, discounted to 2022] [a]

	3% Discount rate	7% Discount rate
Net Benefits	15,000	12,000

[a] Rows may not appear to add correctly due to rounding.

[b] The annualized present value of costs and benefits are calculated over a 20-year period from 2023 to 2042. Monetized benefits include those related to public health associated with reductions in $PM_{2.5}$ and ozone concentrations. The health benefits are associated with several point estimates and are presented at real discount rates of 3 and 7 percent. Several categories of benefits remain unmonetized and are thus not reflected in the table. Non-monetized benefits include important climate benefits from reductions in CO_2 emissions. The U.S. District Court for the Western District of Louisiana has issued an injunction concerning the monetization of the benefits of greenhouse gas emission reductions by EPA and other defendants. See *Louisiana* v. *Biden*, No. 21–cv–01074–JDC–KK (W.D. La. Feb. 11, 2022). Therefore, such values are not presented in the benefit-cost analysis of this proposal conducted pursuant to E.O. 12866. Please see Chapter 5, Section 5.2 of the RIA for more discussion. In addition, there are important unquantified water quality benefits and benefits associated with reductions in other air pollutants.

[c] The costs presented in this table are consistent with the costs presented in Chapter 4 of the RIA. To estimate these annualized costs, EPA uses a conventional and widely accepted approach that applies a capital recovery factor (CRF) multiplier to capital investments and adds that to the annual incremental operating expenses. Costs were calculated using a 3.76% real discount rate consistent with the rate used in IPM's objective function for cost-minimization.

As shown in Table I.C–1, the PV of the benefits, associated with reductions in $PM_{2.5}$ and ozone concentrations, of this proposed rule, discounted at a 3-percent discount rate, is estimated to be about $250,000 million, with an EAV of about $17,000 million. At a 7-percent discount rate, the PV of the benefits is estimated to be $150,000 million, with an EAV of about $14,000 million. The PV of the compliance costs, discounted at a 3-percent rate, is estimated to be about $22,000 million, with an EAV of about $1,500 million. At a 7-percent discount rate, the PV of the compliance costs is estimated to be about $14,000 million, with an EAV of about $1,300 million.

II. Public Participation

A. Written Comments

Submit your comments, identified by Docket ID No. EPA–HQ–OAR–2021–0668 at *https://www.regulations.gov* (our preferred method), or the other methods identified in the **ADDRESSES** section. Once submitted, comments cannot be edited or removed from the docket. The EPA may publish any comment received to its public docket. Do not submit to EPA's docket at *https://www.regulations.gov* any information you consider to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Multimedia submissions (audio, video, etc.) must be accompanied by a written comment. The written comment is considered the official comment and should include discussion of all points you wish to make. The EPA will generally not consider comments or comment contents located outside of the primary submission (*i.e.,* on the web, cloud, or other file sharing system). For additional submission methods, the full EPA public comment policy, information about CBI or multimedia submissions, and general guidance on making effective comments, please visit *https://www.epa.gov/dockets/commenting-epa-dockets.*

Due to public health concerns related to COVID–19, the EPA Docket Center and Reading Room are open to the public by appointment only. Our Docket Center staff also continues to provide remote customer service via email, phone, and webform. Hand deliveries or couriers will be received by scheduled appointment only. For further information and updates on EPA Docket Center services, please visit us online at *https://www.epa.gov/dockets.*

The EPA continues to carefully and continuously monitor information from the Centers for Disease Control and Prevention (CDC), local area health departments, and our Federal partners so that we can respond rapidly as conditions change regarding COVID–19.

B. Submitting Confidential Business Information

Do not submit information containing CBI to the EPA through *https://www.regulations.gov.* Clearly mark the part or all of the information that you claim to be CBI. For CBI information on any digital storage media that you mail to the EPA, mark the outside of the digital storage media as CBI and then identify electronically within the digital storage media the specific information that is claimed as CBI. In addition to one complete version of the comments that includes information claimed as CBI, you must submit a copy of the comments that does not contain the information claimed as CBI directly to the public docket through the procedures outlined in *Instructions* earlier. If you submit any digital storage media that does not contain CBI, mark the outside of the digital storage media clearly that it does not contain CBI. Information not marked as CBI will be included in the public docket and the EPA's electronic public docket without prior notice. Information marked as CBI will not be disclosed except in accordance with procedures set forth in 40 Code of Federal Regulations (CFR) part 2. Our preferred method to receive CBI is for it to be transmitted to electronically using email attachments, File Transfer Protocol (FTP), or other online file sharing services (*e.g.,* Dropbox, OneDrive, Google Drive). Electronic submissions must be transmitted directly to the OAQPS CBI Office using the email address, *oaqpscbi@epa.gov,* and should include clear CBI markings as described above. If assistance is needed with submitting large electronic files that exceed the file size limit for email attachments, and if you do not have your own file sharing service, please email *oaqpscbi@epa.gov* to request a file transfer link. If sending CBI information through the postal service, please send it to the following address: OAQPS Document Control Officer (C404–02), OAQPS, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711, Attention Docket ID No. EPA–HQ–OAR–2021–0668. The mailed CBI material should be double wrapped and clearly marked. Any CBI markings should not show through the outer envelope.

C. Participation in Virtual Public Hearing

Please note that because of current CDC recommendations, as well as state and local orders for social distancing to limit the spread of COVID–19, the EPA cannot hold in-person public meetings at this time.

The EPA will begin pre-registering speakers for the hearing no later than 1 business day after publication of this document in the **Federal Register**. To register to speak at the virtual hearing, please use the online registration form available at *https://www.epa.gov/csapr/csapr-2015-ozone-naaqs.* The last day to pre-register to speak at the hearing will be April 21, 2022. The EPA will post a general agenda for the hearing that will list pre-registered speakers in approximate order at: *https://www.epa.gov/csapr/csapr-2015-ozone-naaqs.*

The virtual public hearing will be held on via teleconference on April 21, 2022. The virtual public hearing will convene at 10:00 a.m. Eastern Time (ET) and will conclude at 7:00 p.m. ET. The EPA may close a session 15 minutes after the last pre-registered speaker has testified if there are no additional speakers. For information or questions about the public hearing, please contact Ms. Holly DeJong at *Dejong.holly@epa.gov.* The EPA will announce further details at *https://www.epa.gov/csapr/csapr-2015-ozone-naaqs.*

The EPA will make every effort to follow the schedule as closely as possible on the day of the hearing; however, please plan for the hearings to run either ahead of schedule or behind schedule.

Each commenter will have 5 minutes to provide oral testimony. The EPA encourages commenters to provide the EPA with a copy of their oral testimony electronically (via email) by emailing it to *Dejong.holly@epa.gov.* The EPA also recommends submitting the text of your oral comments as written comments to the rulemaking docket.

The EPA may ask clarifying questions during the oral presentations, but will not respond to the presentations at that time. Written statements and supporting information submitted during the comment period will be considered with the same weight as oral comments and supporting information presented at the public hearing.

Please note that any updates made to any aspect of the hearing will be posted online at *https://www.epa.gov/csapr/csapr-2015-ozone-naaqs.* While the EPA expects the hearing to go forward as set forth above, please monitor our website or contact Ms. Holly DeJong at *Dejong.holly@epa.gov* to determine if there are any updates. The EPA does not intend to publish a document in the **Federal Register** announcing updates.

If you require the services of a translator or special accommodations such as audio description, please pre-register for the hearing and describe your needs by April 18, 2022. EPA may not be able to arrange accommodations without advanced notice.

III. General Information

A. Does this action apply to me?

This proposed rule affects EGU and non-EGU sources, and regulates the groups identified in Table III.A–1.

TABLE III.A–1—REGULATED GROUPS

Industry group	NAICS
Fossil fuel-fired electric power generation	221112
Pipeline Transportation of Natural Gas	4862
Cement and Concrete Product Manufacturing	3273
Iron and Steel Mills and Ferroalloy Manufacturing	3311
Glass and Glass Product Manufacturing	3272
Basic Chemical Manufacturing	3251
Petroleum and Coal Products Manufacturing	3241
Pulp, Paper, and Paperboard Mills	3221

This table is not intended to be exhaustive, but rather provides a guide for readers regarding entities likely to be regulated by this proposed rule. This table lists the types of entities that the EPA is now aware could potentially be regulated by this proposed rule. Other types of entities not listed in the table could also be regulated. For example, the EPA is requesting comment in Section VI.B.3 of this proposed rule on potential control strategies for sources outside of the categories listed in the Table III.A.1, such as municipal waste combustors (MWCs). To determine whether your EGU entity is proposed to be regulated by this proposed rule, you should carefully examine the applicability criteria found in 40 CFR 97.1004, which the EPA is not proposing to alter in this proposed rule. If you have questions regarding the applicability of this proposed rule to a particular entity, consult the person listed in the **FOR FURTHER INFORMATION CONTACT** section.

B. What action is the Agency taking?

The EPA evaluated whether interstate ozone transport emissions from upwind states are significantly contributing to nonattainment, or interfering with maintenance, of the 2015 ozone NAAQS in any downwind state using the same 4-step interstate transport framework that was developed in previous ozone transport rulemakings. The EPA is proposing to find that emissions reductions are required from EGU and non-EGU sources in a total of 26 upwind states to eliminate significant contribution to downwind air quality problems for the 2015 ozone standard under the interstate transport provision of the CAA. The EPA will ensure that these NO_X emissions reductions are achieved by issuing proposed FIP requirements for 26 states: Alabama, Arkansas, California, Delaware, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Tennessee, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming.

The EPA is proposing to revise the existing CSAPR Group 3 Trading Program to include additional states beginning in the 2023 ozone season. EGUs in five states not currently covered by any CSAPR trading program for seasonal NO_X emissions—Delaware, Minnesota, Nevada, Utah, and Wyoming—would be added to the CSAPR Group 3 Trading Program under this proposed rule. EGUs in twelve states currently participating in the Group 3 Trading Program would remain in the program under this proposed rule: Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, New Jersey, New York, Ohio, Pennsylvania, Virginia, and West Virginia. EGUs in eight states (Alabama, Arkansas, Mississippi, Missouri, Oklahoma, Tennessee, Texas, and Wisconsin) will transition from the CSAPR Group 2 Trading Program to the CSAPR Group 3 Trading Program under this proposed rule beginning in the 2023 ozone season. The EPA proposes to establish control stringency levels reflecting installation of state-of-the-art combustion controls on certain covered EGU sources in emissions budgets beginning in the 2024 ozone season. The EPA proposes to establish control stringency levels reflecting installation of new SCR or SNCR controls on certain covered EGU sources in emissions budgets beginning in the 2026 ozone season.

As a complement to the ozone season emissions budgets, the EPA is also proposing to establish backstop daily emissions rates of 0.14 lb/mmBtu for coal-fired steam units greater than or equal to 100 MW in covered states. The backstop emissions rates will first apply in 2024 for coal-fired steam sources with existing SCRs, and in 2027 for those currently without SCRs.

In this proposed rule, the EPA is proposing to require emissions limitations for non-EGU sources in 23 states: Arkansas, California, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Texas, Utah, Virginia, West Virginia, Wisconsin, and

Wyoming. In these states, EPA is proposing to require emissions limitations for the following unit types in non-EGU industries: Furnaces in Glass and Glass Product Manufacturing; boilers and furnaces in Iron and Steel Mills and Ferroalloy Manufacturing; kilns in Cement and Cement Product Manufacturing; reciprocating internal combustion engines in Pipeline Transportation of Natural Gas; and high-emitting equipment and large boilers in Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mill. See Table III.A–1 for a list of NAICS codes for each entity included for regulation under this proposed rule.

The proposed rule would reduce the transport of ozone precursor emissions to downwind areas, which is protective of human health and the environment because acute and chronic exposure to ozone are both associated with negative health impacts. Ozone exposure is also associated with negative effects on ecosystems. Additional information on the human health and environmental benefits from the air quality issues addressed by this proposed rule are included in Section IV of this proposed rule.

C. What is the Agency's legal authority for taking this action?

1. Statutory Authority

The statutory authority for this proposed rule is provided by the CAA as amended (42 U.S.C. 7401 *et seq.*). Specifically, sections 110 and 301 of the CAA provide the primary statutory underpinnings for this proposed rule. The most relevant portions of CAA section 110 are subsections 110(a)(1), 110(a)(2) (including 110(a)(2)(D)(i)(I)), 110(c)(1), and 110(k)(6)).

CAA section 110(a)(1) provides that states must make SIP submissions ''within 3 years (or such shorter period as the Administrator may prescribe) after the promulgation of a national primary ambient air quality standard (or any revision thereof),'' and that these SIP submissions are to provide for the ''implementation, maintenance, and enforcement'' of such NAAQS.[18] The statute directly imposes on states the duty to make these SIP submissions, and the requirement to make the submissions is not conditioned upon the EPA taking any action other than promulgating a new or revised NAAQS.[19]

[18] 42 U.S.C. 7410(a)(1).

[19] *See EPA* v. *EME Homer City Generation, L.P.*, 572 U.S. 489, 509–10 (2014).

The EPA has historically referred to SIP submissions made for the purpose of satisfying the applicable requirements of CAA sections 110(a)(1) and 110(a)(2) as ''infrastructure SIP'' or ''iSIP'' submissions. CAA section 110(a)(1) addresses the timing and general requirements for iSIP submissions, and CAA section 110(a)(2) provides more details concerning the required content of these submissions.[20] It includes a list of specific elements that ''[e]ach such plan'' must address.[21]

CAA section 110(c)(1) requires the Administrator to promulgate a FIP at any time within two years after the Administrator: (1) Finds that a state has failed to make a required SIP submission; (2) finds a SIP submission to be incomplete pursuant to CAA section 110(k)(1)(C); or (3) disapproves a SIP submission. This obligation applies unless the state corrects the deficiency through a SIP revision that the Administrator approves before the FIP is promulgated.[22]

CAA section 110(a)(2)(D)(i)(I), also known as the ''good neighbor'' provision, provides the primary basis for this proposed rule.[23] It requires that each state SIP include provisions sufficient to ''prohibit[ ], consistent with the provisions of this subchapter, any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will—(I) contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any [NAAQS].'' [24] The EPA often refers to the emissions reduction requirements under this provision as ''good neighbor obligations'' and submissions addressing these requirements as ''good neighbor SIPs.''

Once EPA promulgates a NAAQS, the EPA must designate areas as being in ''attainment'' or ''nonattainment'' of the NAAQS, or ''unclassifiable.'' CAA section 107(d).[25] For ozone, nonattainment is further split into five classifications based on the severity of the violation—Marginal, Moderate, Serious, Severe, or Extreme. Higher classifications provide states with progressively more time to attain while

[20] 42 U.S.C. 7410(a)(2).

[21] EPA's general approach to infrastructure SIP submissions is explained in greater detail in individual notices acting or proposing to act on state infrastructure SIP submissions and in guidance. *See, e.g.,* Memorandum from Stephen D. Page on Guidance on Infrastructure State Implementation Plan (SIP) Elements under Clean Air Act Sections 110(a)(1) and 110(a)(2) (September 13, 2013).

[22] 42 U.S.C. 7410(c)(1).

[23] 42 U.S.C. 7410(a)(2)(D)(i)(I).

[24] *Id.*

[25] 42 U.S.C. 7407(d).

imposing progressively more stringent control requirements. *See* CAA sections 181, 182.[26] In general, states with nonattainment areas classified as Moderate or higher must submit plans to EPA to bring these areas into attainment according to the statutory schedule. CAA section 182.[27] If an area fails to attain the NAAQS by the attainment date associated with its classification, it is ''bumped up'' to the next classification. CAA section 181(b).[28]

Section 301(a)(1) of the CAA gives the Administrator the general authority to prescribe such regulations as are necessary to carry out functions under the Act.[29] Pursuant to this section, EPA has authority to clarify the applicability of CAA requirements and undertake other rulemaking action as necessary to implement CAA requirements. CAA section 301 affords the Agency any additional authority that may be needed in order to make certain other changes to its regulations under 40 CFR parts 52, 75, 78, and 97, in order to effectuate the purposes of the Act. Such changes are discussed in Section X of this proposed rule.

Section 110(k)(6) of the CAA gives the Administrator authority, without any further submission from a state, to revise certain prior actions, including actions to approve SIPs, upon determining that those actions were in error.[30] The EPA proposes to make an error correction under CAA section 110(k)(6) with respect to its prior approval of the 2015 ozone transport SIP submission from the State of Delaware. This is further discussed in Section IV.C.1 of the proposed rule.

Tribes are not required to submit state implementation plans. However, as explained in EPA's regulations outlining Tribal Clean Air Act authority, the EPA is authorized to promulgate FIPs for Indian country as necessary or appropriate to protect air quality if a tribe does not submit, and obtain EPA approval of, an implementation plan. *See* 40 CFR 49.11(a); *see also* CAA section 301(d)(4).[31] In this proposed rule, the EPA proposes an ''appropriate or necessary'' finding under CAA section 301(d) and proposes tribal FIP(s) as necessary to implement the relevant requirements. This is further discussed in Section IV.C.2 of the proposed rule.

[31] 42 U.S.C. 7601(d)(4).

D. What actions has EPA previously issued to address regional ozone transport?

The EPA has issued several major rules interpreting and clarifying the requirements of CAA section 110(a)(2)(D)(i)(I) with respect to the regional transport of ozone. These rules, and the associated court decisions addressing these rules, summarized here, provide important direction regarding the requirements of CAA section 110(a)(2)(D)(i)(I).

The ''NO_X SIP Call,'' promulgated in 1998, addressed the good neighbor provision for the 1979 1-hour ozone NAAQS.[32] The rule required 22 states and the District of Columbia to amend their SIPs to reduce NO_X emissions that contribute to ozone nonattainment in downwind states. The EPA set ozone season NO_X budgets for each state, and the states were given the option to participate in a regional allowance trading program, known as the NO_X Budget Trading Program.[33] The D.C. Circuit largely upheld the NO_X SIP Call in *Michigan* v. *EPA,* 213 F.3d 663 (D.C. Cir. 2000), *cert. denied,* 532 U.S. 904 (2001).

EPA's next rule addressing the good neighbor provision, the Clean Air Interstate Rule (CAIR), was promulgated in 2005 and addressed both the 1997 fine particulate matter ($PM_{2.5}$) NAAQS and 1997 ozone NAAQS.[34] CAIR required SIP revisions in 28 states and the District of Columbia to reduce emissions of sulfur dioxide (SO_2) or NO_X—important precursors of regionally transported $PM_{2.5}$ (SO_2 and annual NO_X) and ozone (summer-time NO_X). As in the NO_X SIP Call, states were given the option to participate in regional trading programs to achieve the reductions. When the EPA promulgated the final CAIR in 2005, the EPA also issued findings that states nationwide had failed to submit SIPs to address the requirements of CAA section 110(a)(2)(D)(i) with respect to the 1997 $PM_{2.5}$ and 1997 ozone NAAQS.[35] On March 15, 2006, the EPA promulgated FIPs to implement the emissions reductions required by CAIR.[36] CAIR was remanded to EPA by the D.C. Circuit in *North Carolina* v. *EPA,* 531 F.3d 896 (D.C. Cir. 2008), *modified on reh'g,* 550 F.3d 1176. For more information on the legal issues underlying CAIR and the D.C. Circuit's holding in *North Carolina,* refer to the preamble of the CSAPR rule.[37]

In 2011, the EPA promulgated CSAPR to address the issues raised by the remand of CAIR. CSAPR addressed the two NAAQS at issue in CAIR and additionally addressed the good neighbor provision for the 2006 $PM_{2.5}$ NAAQS.[38] CSAPR required 28 states to reduce SO_2 emissions, annual NO_X emissions, or ozone season NO_X emissions that significantly contribute to other states' nonattainment or interfere with other states' abilities to maintain these air quality standards.[39] To align implementation with the applicable attainment deadlines, the EPA promulgated FIPs for each of the 28 states covered by CSAPR. The FIPs require EGUs in the covered states to participate in regional trading programs to achieve the necessary emissions reductions. Each state can submit a good neighbor SIP at any time that, if approved by EPA, would replace the CSAPR FIP for that state.

CSAPR was the subject of an adverse decision by the D.C. Circuit in August 2012.[40] However, this decision was reversed in April 2014 by the Supreme Court, which largely upheld the rule, including EPA's approach to addressing interstate transport in CSAPR. *EPA* v. *EME Homer City Generation, L.P.,* 572 U.S. 489 (2014) (*EME Homer City I*). The rule was remanded to the D.C. Circuit to consider claims not addressed by the Supreme Court. *Id.* In July 2015 the D.C. Circuit generally affirmed EPA's interpretation of various statutory provisions and EPA's technical decisions. *EME Homer City Generation, L.P.* v. *EPA,* 795 F.3d 118 (2015) (*EME Homer City II*). However, the court remanded the rule without vacatur for reconsideration of EPA's emissions budgets for certain states, which the court found may have over-controlled those states' emissions with respect to the downwind air quality problems to which the states were linked. *Id.* at 129–30, 138. For more information on the legal issues associated with CSAPR and the Supreme Court's and D.C. Circuit's decisions in the *EME Homer City* litigation, refer to the preamble of the CSAPR Update.[41]

In 2016, the EPA promulgated the CSAPR Update to address interstate transport of ozone pollution with respect to the 2008 ozone NAAQS.[42] The final rule updated the CSAPR ozone season NO_X emissions budgets for 22 states to achieve cost-effective and immediately feasible NO_X emissions reductions from EGUs within those states.[43] The EPA aligned the analysis and implementation of the CSAPR Update with the 2017 ozone season in order to assist downwind states with timely attainment of the 2008 ozone NAAQS.[44] The CSAPR Update implemented the budgets through FIPs requiring sources to participate in a revised CSAPR NO_X ozone season trading program beginning with the 2017 ozone season. As under CSAPR, each state could submit a good neighbor SIP at any time that, if approved by the EPA, would replace the CSAPR Update FIP for that state. The final CSAPR Update also addressed the remand by the D.C. Circuit of certain states' CSAPR phase 2 ozone season NO_X emissions budgets in *EME Homer City II.*

In December 2018, the EPA promulgated the CSAPR ''Close-Out,'' which determined that no further enforceable reductions in emissions of NO_X were required with respect to the

[32] *Finding of Significant Contribution and Rulemaking for Certain States in the Ozone Transport Assessment Group Region for Purposes of Reducing Regional Transport of Ozone,* 63 FR 57356 (Oct. 27, 1998). As originally promulgated, the NO_X SIP Call also addressed good neighbor obligations under the 1997 8-hour ozone NAAQS, but EPA subsequently stayed and later rescinded the rule's provisions with respect to that standard. *See* 84 FR 8422 (March 8, 2019).

[33] ''Allowance Trading,'' sometimes referred to as ''cap and trade,'' is an approach to reducing pollution that has been used successfully to protect human health and the environment. The design elements of EPA's most recent trading programs are discussed in Section VII.B.1.a of this proposed rule.

[34] *Rule To Reduce Interstate Transport of Fine Particulate Matter and Ozone (Clean Air Interstate Rule); Revisions to Acid Rain Program; Revisions to the* NO_X *SIP Call,* 70 FR 25162 (May 12, 2005).

[35] 70 FR 21147 (April 25, 2005).

[36] 71 FR 25328 (April 28, 2006).

[37] *Federal Implementation Plans: Interstate Transport of Fine Particulate Matter and Ozone and Correction of SIP Approvals,* 76 FR 48208, 48217 (August 8, 2011).

[38] 76 FR 48208.

[39] CSAPR was revised by several rulemakings after its initial promulgation in order to revise certain states' budgets and to promulgate FIPs for five additional states addressing the good neighbor obligation for the 1997 ozone NAAQS. *See* 76 FR 80760 (December 27, 2011); 77 FR 10324 (February 21, 2012); 77 FR 34830 (June 12, 2012).

[40] On August 21, 2012, the D.C. Circuit issued a decision in *EME Homer City Generation, L.P.* v. *EPA,* 696 F.3d 7 (D.C. Cir. 2012), vacating CSAPR. The EPA sought review with the D.C. Circuit *en banc* and the D.C. Circuit declined to consider EPA's appeal *en banc. EME Homer City Generation, L.P.* v. *EPA,* No. 11–1302 (D.C. Cir. January 24, 2013), ECF No. 1417012 (denying EPA's motion for rehearing en banc).

[41] *Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS,* 81 FR 74504, 74511 (October 26, 2016).

[42] 81 FR 74504.

[43] One state, Kansas, was made newly subject to ozone season NO_X requirements by the CSAPR Update. All other CSAPR Update states were already subject to ozone season NO_X requirements under CSAPR.

[44] 81 FR 74516. EPA's final 2008 Ozone NAAQS SIP Requirements Rule, 80 FR 12264, 12268 (March 6, 2015), revised the attainment deadline for ozone nonattainment areas designated as Moderate to July 20, 2018. *See* 40 CFR 51.1103. In order to demonstrate attainment by this deadline, states were required to rely on design values calculated using ozone season data from 2015 through 2017, since the July 20, 2018, deadline did not afford enough time for measured data of the full 2018 ozone season.

2008 ozone NAAQS for 20 of the 22 eastern states covered by the CSAPR Update, and reflected that determination in revisions to the existing state-specific sections of the CSAPR Update regulations for those states.[45]

The CSAPR Update and the CSAPR Close-Out were both subject to legal challenges in the D.C. Circuit. *Wisconsin* v. *EPA,* 938 F.3d 303 (D.C. Cir. 2019) (*Wisconsin*); *New York* v. *EPA,* 781 Fed. App'x 4 (D.C. Cir. 2019) (*New York*). In September 2019, the D.C. Circuit upheld the CSAPR Update in virtually all respects but remanded the rule because it was partial in nature and did not fully eliminate upwind states' significant contribution to nonattainment or interference with maintenance of the 2008 ozone NAAQS by ''the relevant downwind attainment deadlines'' in the CAA. *Wisconsin,* 938 F.3d at 313–15. In October 2019, the D.C. Circuit vacated the CSAPR Close-Out on the same grounds that it remanded the CSAPR Update in *Wisconsin,* specifically that the Close-Out rule did not address good neighbor obligations by ''the next applicable attainment date'' of downwind states. *New York,* 781 Fed. App'x at 7.[46]

In response to the *Wisconsin* remand of the CSAPR Update and the *New York* vacatur of the CSAPR Close-Out, the EPA promulgated the Revised CSAPR Update on April 30, 2021.[47] The Revised CSAPR Update found that the CSAPR Update was a full remedy for nine of the covered states. For the 12 remaining states, the EPA found that their projected 2021 ozone season NO_X emissions significantly contribute to downwind states' nonattainment or maintenance problems. The EPA issued new or amended FIPs for these 12 states and required implementation of revised emissions budgets for EGUs beginning with the 2021 ozone season. Based on EPA's assessment of remaining air quality issues and additional emissions control strategies for EGUs and emissions sources in other industry sectors (non-EGUs), the EPA determined that the NO_X emissions reductions achieved by the Revised CSAPR Update fully eliminated these states' significant contributions to downwind air quality problems for the 2008 ozone NAAQS. As under the CSAPR and the CSAPR Update, each state can submit a good neighbor SIP at any time that, if approved by EPA, would replace the Revised CSAPR Update FIP for that state.[48]

IV. Air Quality Issues Addressed and Overall Approach for the Proposed Rule

A. The Interstate Ozone Transport Air Quality Challenge

1. Nature of Ozone and the Ozone NAAQS

Ground-level ozone is not emitted directly into the air but is created by chemical reactions between NO_X and volatile organic compounds (VOCs) in the presence of sunlight. Emissions from electric utilities and industrial facilities, motor vehicles, gasoline vapors, and chemical solvents are some of the major sources of NO_X and VOCs.

Because ground-level ozone formation increases with temperature and sunlight, ozone levels are generally higher during the summer months. Increased temperature also increases emissions of volatile man-made and biogenic organics and can also indirectly increase NO_X emissions (*e.g.,* increased electricity generation for air conditioning).

On October 1, 2015, the EPA strengthened the primary and secondary ozone standards to 70 ppb as an 8-hour level.[49] Specifically, the standards require that the 3-year average of the fourth highest 24-hour maximum 8-hour average ozone concentration may not exceed 70 ppb as a truncated value (*i.e.,* digits to right of decimal removed).[50] In general, areas that exceed the ozone standard are designated as nonattainment areas, pursuant to the designations process under CAA section 107, and are subject to heightened planning requirements depending on the degree of severity of their nonattainment classification, *see* CAA sections 181, 182.

In the process of setting the 2015 ozone NAAQS, the EPA noted that the conditions conducive to the formation of ozone (*i.e.,* seasonally-dependent factors such as ambient temperature, strength of solar insolation, and length of day) differ by location, and that the Agency believes it is important that ozone monitors operate during all periods when there is a reasonable possibility of ambient levels approaching the level of the NAAQS. At that time, the EPA stated that ambient ozone concentrations in many areas could approach or exceed the level of the NAAQS, more frequently and during more months of the year compared with the historical ozone season monitoring lengths. Consequently, the EPA extended the ozone monitoring season for many locations. *See* 80 FR 65416 for more details.

Furthermore, the EPA stated that in addition to being affected by changing emissions, future ozone concentrations may also be affected by climate change. Modeling studies in the EPA's Interim Assessment (U.S. EPA, 2009a) that are cited in support of the 2009 Endangerment Finding under CAA section 202(a) (74 FR 66496, Dec. 15, 2009) as well as a recent assessment of potential climate change impacts (Fann et al., 2015) project that climate change may lead to future increases in summer ozone concentrations across the contiguous U.S.[51] (80 FR 65300). The increase in ozone results from changes in local weather conditions, including temperature and atmospheric circulation patterns, as well as changes in ozone precursor emissions that are influenced by meteorology (Nolte et al., 2018). While the projected impact may not be uniform, climate change has the potential to increase average summertime ozone relative to a future without climate change.[52] [53] [54] Climate

[45] *Determination Regarding Good Neighbor Obligations for the 2008 Ozone National Ambient Air Quality Standard,* 83 FR 65878, 65882 (Dec. 21, 2018). After promulgating the CSAPR Update and before promulgating the CSAPR Close-Out, the EPA approved a SIP from Kentucky resolving the Commonwealth's good neighbor obligations for the 2008 ozone NAAQS. 83 FR 33730 (July 17, 2018). In the Revised CSAPR Update, the EPA made an error correction under CAA section 110(k)(6) to convert this approval to a disapproval, because the Kentucky approval relied on the same analysis which the D.C. Circuit determined to be unlawful in the CSAPR Close-Out.

[46] Subsequently, the D.C. Circuit made clear in a decision reviewing EPA's denial of a petition under CAA section 126 that the holding in *Wisconsin* regarding alignment with downwind area's attainment schedules applies with equal force to the Marginal area attainment date established under CAA section 181(a). *See Maryland* v. *EPA,* 958 F.3d 1185, 1203–04 (D.C. Cir. 2020).

change has the potential to offset some of the improvements in ozone air quality, and therefore some of the improvements in public health, that are expected from reductions in emissions of ozone precursors (80 FR 65300).

2. Ozone Transport

Studies have established that ozone formation, atmospheric residence, and transport occur on a regional scale (*i.e.,* thousands of kilometers) over much of the U.S.[55] While substantial progress has been made in reducing ozone in many areas, the interstate transport of ozone precursor emissions remains an important contributor to peak ozone concentrations and high-ozone days during the summer ozone season.

The EPA has previously concluded in the NO_X SIP Call, CAIR, CSAPR, the CSAPR Update, and the Revised CSAPR Update that a regional NO_X control strategy would be effective in reducing regional-scale transport of ozone precursor emissions. NO_X emissions can be transported downwind as NO_X or as ozone after transformation in the atmosphere. In any given location, ozone pollution levels are impacted by a combination of background ozone concentration, local emissions, and emissions from upwind sources resulting from ozone transport. Downwind states' ability to meet health-based air quality standards such as the NAAQS is challenged by the transport of ozone pollution across state borders. For example, ozone assessments conducted for the October 2015 Regulatory Impact Analysis of the Final Revisions to the National Ambient Air Quality Standards for Ground-Level Ozone continue to show the importance of NO_X emissions for ozone transport. This analysis is included in the docket for this proposal.

Further, studies have found that EGU NO_X emissions reductions can be effective in reducing individual 8-hour peak ozone concentrations and in reducing 8-hour peak ozone concentrations averaged across the ozone season. For example, a study that evaluates the effectiveness on ozone concentrations of EGU NO_X reductions achieved under the NO_X Budget Trading Program (*i.e.,* the NO_X SIP Call) shows that regulating NO_X emissions in that program was highly effective in reducing ozone concentrations during the ozone season.[56]

Previous regional ozone transport efforts, including the NO_X SIP Call, CAIR, CSAPR, the CSAPR Update, and the Revised CSAPR Update, required ozone season NO_X reductions from EGU sources to address interstate transport of ozone. Together with NO_X, EPA has also identified VOCs as a precursor in forming ground-level ozone. Ozone formation chemistry can be ''NO_X-limited,'' where ozone production is primarily determined by the amount of NO_X emissions or ''VOC-limited,'' where ozone production is primarily determined by the amount of VOC emissions.[57] The EPA and others have long regarded NO_X to be the more significant ozone precursor in the context of interstate ozone transport.[58]

The EPA has determined that the regulation of VOCs as an ozone precursor is not necessary to eliminate significant contribution of ozone transport to downwind areas in this proposed rule. As described in Section VI.A of this proposed rule, the EPA examined the results of the contribution modeling performed for this rule to identify the portion of the ozone contribution attributable to anthropogenic NO_X emissions versus VOC emissions from each linked upwind state to each downwind receptor. Our analysis of the ozone contribution from upwind states subject to regulation under this proposed rule demonstrates that the vast majority of the downwind air quality areas are NO_X-limited, rather than VOC-limited. Therefore, the proposed rule's strategy for reducing regional-scale transport of ozone targets NO_X emissions from stationary sources to achieve the most effective reductions of ozone transport over the geography of the affected downwind areas.

Commenters on prior ozone transport rules have asserted that VOC emissions harm underserved and overburdened communities experiencing disproportionate environmental health burdens and facing other environmental injustices. The EPA acknowledges that VOCs can contain toxic chemicals that are detrimental to public health. The EPA conducted a demographic analysis as part of the regulatory impact analysis for the 2015 revisions to the primary and secondary ozone NAAQS. This analysis, which is included in the docket for this proposed rulemaking, found greater representation of minority populations in areas with poor air quality relative to the revised ozone standard than in the U.S. as a whole. The EPA concluded that populations in these areas would be expected to benefit from implementation of future air pollution control actions from state and local air agencies in implementing the strengthened standard. This proposed rule is an example of air pollution control actions implemented by the federal government in support of the more stringent 2015 ozone NAAQS, and populations living in downwind ozone nonattainment areas are expected to benefit from improved air quality that will result from reducing ozone transport. Further discussion of the environmental justice impacts of this proposed rule is located in Section VIII of this proposed rule and in the accompanying regulatory impact analysis, titled ''Regulatory Impact Analysis for the Proposed Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standard'' [EPA–452/D–22–001], which is available in the docket for this rulemaking.

The Agency regulates exposure to toxic pollutant concentrations and ambient exposure to criteria pollutants other than ozone through other sections of the Act, such as the regulation of hazardous air pollutants under CAA section 112 or the process for revising and implementing the NAAQS under CAA sections 107–110. The purpose of the proposed rulemaking is to protect public health and the environment by eliminating significant contribution from 26 states to nonattainment or maintenance of the 2015 ozone NAAQS in order to meet the requirements of the CAA's interstate transport provision. In this proposed rule, the EPA continues to observe that requiring NO_X emissions reductions from stationary sources is an effective strategy for reducing regional ozone transport in the U.S.

In Section VI of this proposed rule, EPA describes the multi-factor test that is used to determine NO_X emissions reductions that are cost-effective and reduce interstate transport of ground-level ozone. Our analysis indicates that the EGU and non-EGU control requirements proposed in this rule will provide meaningful improvements in air quality at the downwind receptors. Based on the implementation schedule

established in Section VII.A of this proposed rule, the EPA proposes to determine that the regulatory requirements included in the proposed rule are as expeditious as practicable and are aligned with the attainment schedule of downwind areas.

3. Health and Environmental Effects

Exposure to ambient ozone causes a variety of negative effects on human health, vegetation, and ecosystems. In humans, acute and chronic exposure to ozone is associated with premature mortality and a number of morbidity effects, such as asthma exacerbation. In ecosystems, ozone exposure causes visible foliar injury, decreases plant growth, and affects ecosystem community composition. *See* EPA's October 2015 Regulatory Impact Analysis of the Final Revisions to the National Ambient Air Quality Standards for Ground-Level Ozone [59] in the docket for this proposal for more information on the human health and ecosystem effects associated with ambient ozone exposure.

B. Proposed Rule Approach

1. The 4-Step Interstate Transport Framework

The EPA first developed a multi-step process to address the requirements of the good neighbor provision in the NO_X SIP Call and CAIR. The Agency built upon this framework and further refined the methodology for addressing interstate transport obligations in subsequent rules such as CSAPR, the CSAPR Update, and the Revised CSAPR Update.[60] In CSAPR, the EPA first articulated a ''4-step framework'' within which to assess interstate transport obligations for ozone. In this proposed action to address interstate transport obligations for the 2015 ozone NAAQS, the EPA is again utilizing the 4-step interstate transport framework. These steps are: (1) Identifying downwind receptors that are expected to have problems attaining the NAAQS (nonattainment receptors) or maintaining the NAAQS (maintenance receptors); (2) determining which upwind states are ''linked'' to these identified downwind receptors based on a numerical contribution threshold; (3) for states linked to downwind air quality problems, identifying upwind emissions on a statewide basis that significantly contribute to downwind nonattainment or interfere with downwind maintenance of the NAAQS, considering cost- and air quality-based factors; and (4) for upwind states that are found to have emissions that significantly contribute to nonattainment or interfere with maintenance of the NAAQS in any downwind state, implementing the necessary emissions reductions through enforceable measures.

a. Step 1 Approach

The EPA proposes to continue to apply the method of the CSAPR Update and the Revised CSAPR Update for identifying nonattainment and maintenance receptors. In the Revised CSAPR Update, the EPA assessed downwind air quality problems using modeled future air quality concentrations for an analytic year aligned with the relevant attainment deadline for the NAAQS under consideration in that rulemaking.[61] Similarly, in CSAPR, downwind air quality problems were assessed using modeled future air quality concentrations for a year aligned with attainment deadlines for the NAAQS considered in that rulemaking. The base case scenario provides an assessment of future air quality conditions that generally accounts for enforceable ''on-the-books'' emissions reductions and provides the most up-to-date forecast of what future emissions would resemble, in the absence of the transport policy in the proposed rule under evaluation. Downwind air quality problems are identified as the locations of monitoring sites that are projected to be unable to attain the NAAQS (''nonattainment receptors'') or as the locations of monitoring sites that are projected to be unable to maintain the NAAQS (''maintenance receptors''). In the CSAPR Update and the Revised CSAPR Update, unlike CSAPR,[62] the EPA also considered currently available monitored air quality data to further inform the identification of projected downwind air quality problems. These same considerations are included for this proposal. Further details regarding the application of Step 1 of the 4-step interstate transport framework in this proposal are described in Section V.D of this proposed rule.

b. Step 2 Approach

The EPA proposes to apply the same approach for identifying which states are contributing to downwind nonattainment and maintenance receptors as it has applied in the three prior CSAPR rulemakings. CSAPR, the CSAPR Update, and the Revised CSAPR Update used a screening threshold of 1 percent of the NAAQS to identify upwind states that were ''linked'' to downwind air pollution problems. States with contributions greater than or equal to the threshold for at least one downwind nonattainment or maintenance receptor identified in Step 1 were identified as needing further evaluation of their good neighbor obligations to downwind states.[63] The EPA evaluated each state's contribution based on the average relative downwind impact calculated over multiple days.[64] States whose air quality impacts to all downwind receptors were below this threshold did not require further evaluation for actions to address transport. In other words, the EPA determined that these states did not contribute to downwind air quality problems and therefore had no emissions reduction obligations under the good neighbor provision. The EPA applies a contribution screening threshold because many downwind ozone nonattainment areas receive transport contributions from a number of upwind states. While the proportion of contribution from a single upwind state may be relatively small, the effect of collective contribution resulting from multiple upwind states may substantially contribute to nonattainment of or interference with maintenance of the NAAQS in downwind areas. The preambles to the

[59] Available at *https://www.epa.gov/sites/default/files/2016-02/documents/20151001ria.pdf.*

[60] *See* CSAPR, Final Rule, 76 FR 48208, 48248–48249 (August 8, 2011); CSAPR Update, Final Rule, 81 FR 74504, 74517–74521 (October 26, 2016).

[61] Specifically, the EPA analyzed 2021 to align with the attainment date for areas classified as Severe nonattainment for the 2008 ozone NAAQS, and because the last full ozone season before that date, in 2020, was already in the past.

[62] In CSAPR, the EPA did not use current monitored air quality conditions, because that data was influenced by the invalidated CAIR rule, which the EPA was replacing with CSAPR. *See* 81 FR 74506, 74531. As the EPA is not replacing an existing transport program in this proposed rule, the Agency proposes to once again consider current monitored data as part of the process for identifying projected receptors for this rulemaking.

[63] For ozone, the impacts include those from VOC and NO_X from all sectors.

[64] The number of days used in calculating the average contribution metric has historically been determined in a manner that is generally consistent with EPA's recommendations for projecting future year ozone design values. Our ozone attainment demonstration modeling guidance at the time of CSAPR recommended using all model-predicted days above the NAAQS to calculate future year design values (*https://www3.epa.gov/ttn/scram/guidance/guide/final-03-pm-rh-guidance.pdf*). In 2014, the EPA issued draft revised guidance that changed the recommended number of days to the top-10 model predicted days (*https://www3.epa.gov/ttn/scram/guidance/guide/Draft-O3-PM-RH-Modeling_Guidance-2014.pdf*). For the CSAPR Update, the EPA transitioned to calculating design values based on this draft revised approach. The revised modeling guidance was finalized in 2019 and, in this regard, EPA is calculating both the ozone design values and the contributions based on a top-10 day approach (*https://www3.epa.gov/ttn/scram/guidance/guide/O3-PM-RH-Modeling_Guidance-2018.pdf*).

proposed and final CSAPR rules discuss the use of the 1 percent threshold for CSAPR. *See* 75 FR 45237 (August 2, 2010); 76 FR 48238 (August 8, 2011). The same metric is discussed in the CSAPR Update, *see* 81 FR 74538, and in the Revised CSAPR Update, *see* 86 FR 23054. In this proposed rule, the EPA updated the air quality modeling data used for determining contributions at Step 2 of the four-step interstate transport framework. The EPA otherwise continues to find that this threshold is appropriate to continue to apply for the 2015 ozone NAAQS. This proposal's application of the Step 2 approach is comprehensively described in Section V of this proposed rule.

c. Step 3 Approach

The EPA proposes to continue to apply the same approach as the prior three CSAPR rulemakings for evaluating ''significant contribution'' at Step 3.[65] For states that are linked in Step 3 to downwind air quality problems, CSAPR, the CSAPR Update, and the Revised CSAPR Update evaluated NO_X reduction potential, cost, and downwind air quality improvements available at various mitigation technology breakpoints (represented by cost thresholds) in the multi-factor test. In CSAPR, the CSAPR Update, and the Revised CSAPR Update, the EPA selected the technology breakpoint (represented by a cost threshold) that, in general, maximized cost-effectiveness—*i.e.,* that achieved a reasonable balance of incremental NO_X reduction potential and corresponding downwind ozone air quality improvements, relative to the other emissions budget levels evaluated. *See, e.g.,* 81 FR 74550. The EPA determined the level of emissions reductions associated with that level of control stringency to constitute significant contribution to nonattainment or interfere with maintenance of a NAAQS downwind. *See, e.g.,* 86 FR 23116. This approach was upheld by the U.S. Supreme Court in *EPA* v. *EME Homer City.*[66]

The EPA proposes in this action to apply this approach to identify EGU and non-EGU NO_X control stringencies necessary to address significant contribution for the 2015 ozone NAAQS. The EPA applies a multifactor assessment using cost-thresholds, total emissions reduction potential, and downwind air quality effects as key factors in determining a reasonable balance of NO_X controls in light of the downwind air quality problems. EPA's evaluation of available NO_X mitigation strategies for EGUs focuses on the same core set of measures as prior transport rules, and the EPA proposes a control stringency for EGUs from these measures that is commensurate with the nature of the ongoing ozone nonattainment and maintenance problems observed for the 2015 ozone NAAQS. Similarly, in this action, the EPA includes other industrial sources (non-EGUs) in its Step 3 analysis and proposes emissions limitations for certain non-EGU sources as needed to eliminate significant contribution and interference with maintenance. The available reductions and cost-levels for the non-EGU stringency is generally commensurate with the control strategy for EGUs.

In CSAPR, the CSAPR Update, and the Revised CSAPR Update, EPA focused its Step 3 analysis on EGUs. In the Revised CSAPR Update, in response to the *Wisconsin* decision's finding that the EPA had not adequately evaluated potential non-EGU reductions, *see* 938 F.3d at 318, the EPA determined that the available NO_X emissions reductions from non-EGU sources, for purposes of addressing good neighbor obligations for the 2008 ozone NAAQS, at a comparable cost threshold to the required EGU emissions reductions (for which EPA used an adjusted representative cost of $1,800 per ton), and based on the timing of when such measures could be implemented, did not provide a sufficiently meaningful and timely air quality improvement at the downwind receptors before those receptors were projected to resolve. *See* 86 FR 23110. On that basis, the EPA made a finding that emissions reductions from non-EGU sources were not required to eliminate significant contribution to downwind air quality problems under the interstate transport provision for the 2008 ozone NAAQS. In this proposal, EPA's ''significant contribution'' analysis at Step 3 of the 4-step framework includes a comprehensive evaluation of major stationary source non-EGU industries in the linked upwind states. The EPA is proposing to find that emissions from certain non-EGU sources in the upwind states significantly contribute to downwind air quality problems for the 2015 ozone NAAQS, and that cost-effective emissions reductions from these sources are required to eliminate significant contribution under the interstate transport provision. Therefore, this proposed rule includes required emissions reductions from non-EGU sources in upwind states to fulfill interstate transport obligations for the 2015 ozone NAAQS. This analysis is described fully in Section VI of the proposed rule.

In this proposed rule, the EPA also continues to apply its approach for assessing and avoiding ''over-control.'' In *EME Homer City,* the Supreme Court held that ''EPA cannot require a State to reduce its output of pollution by more than is necessary to achieve attainment in every downwind State or at odds with the one-percent threshold the Agency has set.'' 572 U.S. at 521. The Court acknowledged that ''instances of 'over-control' in particular downwind locations may be incidental to reductions necessary to ensure attainment elsewhere.'' *Id.* at 492.

> ''Because individual upwind States often 'contribute significantly' to nonattainment in multiple downwind locations, the emissions reductions required to bring one linked downwind State into attainment may well be large enough to push other linked downwind States over the attainment line. As the Good Neighbor Provision seeks attainment in *every* downwind State, however, exceeding attainment in one State cannot rank as 'over-control' unless unnecessary to achieving attainment in *any* downwind State. Only reductions unnecessary to downwind attainment *anywhere* fall outside the Agency's statutory authority.''

Id. at 522 (footnotes excluded).

The Court further explained that ''while EPA has a statutory duty to avoid over-control, the Agency also has a statutory obligation to avoid 'under-control,' *i.e.,* to maximize achievement of attainment downwind.'' *Id.* at 523. Therefore, in the CSAPR Update and Revised CSAPR Update, the EPA evaluated possible over-control by considering whether an upwind state is linked solely to downwind air quality problems that can be resolved at a lower cost threshold, or if upwind states would reduce their emissions at a lower cost threshold to the extent that they would no longer meet or exceed the 1 percent air quality contribution threshold. *See, e.g.,* 81 FR at 74551–52. *See also Wisconsin,* 938 F.3d at 325

[65] For simplicity, the EPA (and courts) at times will refer to the Step 3 analysis as determining ''significant contribution''; however, EPA's approach at Step 3 also implements the ''interference with maintenance'' prong of the good neighbor provision, by also addressing emissions that impact the maintenance receptors identified at Step 1. *See* 86 FR 23074 (''In effect, EPA's determination of what level of upwind contribution constitutes 'interference' with a maintenance receptor is the same determination as what constitutes 'significant contribution' for a nonattainment receptor. Nonetheless, this continues to give independent effect to prong 2 because the EPA applies a broader definition for identifying maintenance receptors, which accounts for the possibility of problems maintaining the NAAQS under realistic potential future conditions.'').

[66] *EPA* v. *EME Homer City Generation, L.P.,* 572 U.S. 489 (2014).

(over-control must be proven through a "'particularized, as-applied challenge'") (quoting *EME Homer City Generation,* 572 U.S. at 523–24). The EPA continues to apply this framework for assessing over-control in this proposed rule, and, as discussed in Section VI.D.4 of this proposed rule, does not find any over-control at the proposed stringency to be sufficiently certain to warrant a relaxation in requirements for the sources in any covered state.

This evaluation of cost, NO_X reductions, and air quality improvements, including consideration of whether there is proven over-control, results in EPA's determination of the appropriate level of upwind control stringency that would result in elimination of emissions that significantly contribute to nonattainment or interfere with maintenance of the NAAQS in downwind areas.

d. Step 4 Approach

The EPA proposes an approach similar to its prior transport rulemakings to implement the necessary emissions reductions through permanent and enforceable measures. The EPA proposes to require EGU sources to participate in an emissions trading program and proposes additional enhancements to the trading regime to maintain the selected control stringency over time and improve emissions performance at individual units, offering a necessary measure of assurance that emissions controls will be operated throughout the ozone season. For non-EGUs, the EPA proposes permanent and enforceable emissions rate limits and work practice standards, and associated compliance requirements, on several types of NO_X-emitting combustion units across several industrial sectors. The measures for both EGUs and non-EGUs are proposed to be required throughout the May 1–September 30 ozone season annually. The EGU program will begin with the 2023 ozone season, and non-EGU implementation will begin with the 2026 ozone season. Refer to Section VII.A of this proposed rule for details on the implementation schedule.

Based on the EPA's experience in implementing prior transport rulemakings, the Agency is proposing several enhancements to its trading-program approach for implementing good neighbor requirements for EGUs. In CSAPR, the CSAPR Update, and the Revised CSAPR Update, the EPA established interstate trading programs for EGUs to implement the necessary emissions reductions. In each of these rules, EGUs in each covered state are assigned an emissions budget for their collective emissions. Emissions allowances are allocated to units covered by the trading program, and the covered units then surrender allowances after the close of each control period, usually in an amount equal to their ozone season EGU NO_X emissions. While these programs have been effective in achieving overall reductions in emissions, experience has shown that these programs may not fully reflect in perpetuity the degree of emissions stringency determined necessary to eliminate significant contribution in Step 3 and may not adequately ensure the control of emissions throughout all days of the ozone season. At the same time, the EPA continues to find that an interstate-trading program approach delivers substantial benefits at Step 4 in terms of affording an appropriate degree of compliance flexibility, certainty in emissions outcomes, data and performance transparency, and cost-effective achievement of a high degree of aggregate emissions reductions. As such, EPA proposes to retain an interstate trading program approach while proposing several enhancements to that approach.

Thus, in this rulemaking, the EPA is proposing to include budget-setting procedures in the regulations that will allow state emissions budgets for control periods in 2025 and later years to reflect more current data on the composition and utilization of the EGU fleet (*e.g.,* the 2025 budgets would reflect 2023 data, the 2026 budgets would reflect 2024 data, etc.). These enhancements would enable the trading program to better maintain over time the selected control stringency that was determined to be necessary to address states' good neighbor obligations with respect to the 2015 ozone NAAQS. In prior programs, where state emissions budgets were static across years rather than calibrated to yearly fleet changes, the EPA has observed instances of units idling their emission controls in the latter years of the program.

In the trading programs established for ozone season NO_X emissions under CSAPR, the CSAPR Update, and the Revised CSAPR Update, the EPA included assurance provisions to limit state emissions to levels below 121 percent of the state's budget by requiring additional allowance surrenders in the instance that emissions in the state exceed this level. This limit on the degree to which a state's emissions can exceed its budget is designed to allow for a certain level of year-to-year variability within power sector emissions to account for fluctuations in demand and EGU operations and is responsive to previous court decisions (see discussion in Section VII.B.4 of this proposed rule). In this action, the EPA again proposes to retain the existing assurance provisions that limit state emissions to levels below 121 percent of the state's budget by requiring additional allowance surrenders in the instance that emissions in the state exceed this level for the 2023 and 2024 control periods. For control periods in 2025 and later years, the EPA is proposing to maintain the same general approach, but with adjustments that account for actual operational conditions in each control period to determine the specific levels above which additional allowance surrenders would be required. In addition, EPA is also proposing several additional enhancements to the EGU trading program in this action, including routine recalibrations of the total amount of banked allowances, unit-specific backstop daily emissions rates for certain units, and unit-specific secondary emissions limitations for units that contribute to exceedances of the assurance levels, to ensure EGU emissions control operation and associated air quality improvements. Implementation of the proposed EGU emissions reductions using a CSAPR NO_X trading program is further described in Section VII.B of this proposed rule.

In this action, the EPA is also proposing to establish emissions limitations for the non-EGU industry sources listed in Table III.A–1. The EPA has the authority to require emissions limitations from stationary sources, as well as from other sources and emissions activities, under CAA section 110(a)(2)(D)(i)(I). The EPA proposes that requiring NO_X emissions reductions through emissions rate limits from certain non-EGU industry sources that the EPA found at Step 3 to be relatively impactful[67] on downwind air quality is an effective strategy for reducing regional ozone transport. Therefore, the EPA proposes NO_X emissions limitations and associated compliance requirements for non-EGU sources to ensure the elimination of significant contribution of ozone precursor emissions required under the interstate

[67] *Section III of the* Non-EGU Screening Assessment memorandum in the docket for this rulemaking describes EPA's approach to evaluating impacts on downwind air quality, considering estimated total, maximum, and average contributions from each industry and the total number of receptors with contributions from each industry.

transport provision for the 2015 ozone NAAQS.

Finally, the EPA proposes that the control measures determined to be required for the identified EGU and non-EGU sources apply to both existing units and any new, modified, or reconstructed units meeting the applicability criteria established in this proposal. This is consistent with EPA's transport actions dating back to the NO_X SIP Call and the NO_X Budget Trading Program. In all CSAPR EGU trading programs, for instance, new EGUs are subject to the program, and the EPA established provisions for the allocation of allowances to such units through ''new unit set asides.'' *See, e.g.,* 86 FR 23126. In the NO_X SIP Call, the EPA required that states cover new and existing units in the relevant source sectors through an enforceable cap or other emissions limitation. *See* 40 CFR 51.121(f). EPA's approach of including new units in the NO_X Budget Trading Program promulgated under EPA's CAA section 126 authority was upheld by the D.C. Circuit in *Appalachian Power* v. *EPA,* 249 F.3d 1032 (2001). The EPA explained in its action:

> Once EPA has determined that the emissions from the existing sources in an upwind State already make a significant contribution to one or more petitioning downwind States, any additional emissions from a new source in that upwind State would also constitute a portion of that significant contribution, unless the emissions from that new source are limited to the level of highly effective controls.

Id. at 1058 (quoting EPA 1999 RTC at 39). The court affirmed this approach: ''Indeed, it would be irrational to enable the EPA to make findings that a group of sources in an upwind state contribute to downwind nonattainment, but then preclude the EPA from regulating new sources that contribute to that same pollution.'' *Id.* at 1057–58. The EPA proposes to adopt the same approach in this action, because this reasoning is equally applicable to addressing interstate transport obligations under CAA section 110(a)(2)(D)(i)(I) for the 2015 ozone NAAQS.

2. FIP Authority for Each State Covered by the Proposed Rule

On October 1, 2015, the EPA promulgated a revision to the 2015 8-hour ozone NAAQS, lowering the level of both the primary and secondary standards to 0.070 parts per million (ppm).[68] These revisions of the NAAQS, in turn, established a 3-year deadline for states to provide SIP submissions addressing infrastructure requirements under CAA sections 110(a)(1) and 110(a)(2), including the good neighbor provision, by October 1, 2018. If the EPA makes a determination that a state failed to submit a SIP, or if EPA disapproves a SIP submission, then the EPA is obligated under CAA section 110(c) to promulgate a FIP for that state within 2 years. For a more detailed discussion of CAA section 110 authority and timelines, refer to Section III.C of this proposed rule.

The EPA is proposing this FIP action now to address twenty-six states' good neighbor obligations for the 2015 ozone NAAQS, but the EPA will not finalize this FIP action for any state unless and until it has issued a final finding of failure to submit or a final disapproval of that state's SIP submission. The EPA is not required to wait to propose a FIP until after the Agency proposes or finalizes a SIP disapproval or makes a finding of failure to submit.[69] CAA section 110(c) authorizes EPA to *promulgate* a FIP ''at any time within 2 years'' of a SIP disapproval or making a finding of failure to submit. Thus, the EPA may promulgate a FIP contemporaneously with or immediately following predicate final action on a SIP (or finding no SIP was submitted). In order to accomplish this, the EPA must necessarily be able to propose a FIP prior to taking final action to disapprove a SIP or make a finding of failure to submit. The Supreme Court recognized this in *EME Homer City* in holding that the EPA is not obligated to first define a state's good neighbor obligations or give the state an additional opportunity to submit an approvable SIP before promulgating a FIP: ''EPA is not obliged to wait two years or postpone its action even a single day: The Act empowers the Agency to promulgate a FIP 'at any time' within the two-year limit.'' [70] Furthermore, the D.C. Circuit in *Wisconsin* held that states and EPA are obligated to fully address good neighbor obligations for ozone ''as expeditiously as practical'' and in no event later than the next relevant downwind attainment dates found in CAA section 181(a).[71] In *Maryland* v. *EPA,* the D.C. Circuit made clear that *Wisconsin's* and *North Carolina's* holdings are fully applicable to the Marginal area attainment date for the 2015 ozone NAAQS,[72] which fell on August 3, 2021.[73] The *Wisconsin* court emphasized that EPA has the authority under CAA section 110 to structure and time its actions in a manner such that the Agency can ensure necessary reductions are achieved by the downwind attainment dates.[74]

On February 22, 2022, the EPA proposed to disapprove 19 good neighbor SIP submissions (Alabama, Arkansas, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, New Jersey, New York, Ohio, Oklahoma, Tennessee, Texas, West Virginia, Wisconsin).[75] The EPA is proposing to

[68] *National Ambient Air Quality Standards for Ozone,* Final Rule, 80 FR 65292 (October 26, 2015). Although the level of the standard is specified in the units of ppm, ozone concentrations are also described in parts per billion (ppb). For example, 0.070 ppm is equivalent to 70 ppb.

[69] The EPA notes there are three consent decrees to resolve three deadline suits related to EPA's duty to act on good neighbor SIP submissions for the 2015 ozone NAAQS. In *New York et al.* v. *Regan, et al.* (No. 1:21–CV–00252, S.D.N.Y.), the EPA agreed to take final action on the 2015 ozone NAAQS good neighbor SIP submissions from Indiana, Kentucky, Michigan, Ohio, Texas, and West Virginia by April 30, 2022; however, if the EPA proposes to disapprove any SIP submissions and proposes a replacement FIP by February 28, 2022, then EPA's deadline to take final action on that SIP submission is extended to December 30, 2022. In *Downwinders at Risk et al.* v. *Regan* (No. 21–cv–03551, N.D. Cal.), the EPA agreed to take final action on the 2015 ozone NAAQS good neighbor SIP submissions from Alabama, Arkansas, Connecticut, Florida, Georgia, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, New Jersey, New York, North Carolina, Ohio, Oklahoma, South Carolina, Tennessee, Texas, West Virginia, and Wisconsin by April 30, 2022; however, if the EPA proposes to disapprove any of these SIP submissions and proposes a replacement FIP by February 28, 2022, then EPA's deadline to take final action on that SIP submission is December 30, 2022. In this CD, the EPA also agreed to take final action on Hawaii's SIP submission by April 30, 2022, and to take final action on the SIP submissions of Arizona, California, Montana, Nevada, and Wyoming by December 15, 2022. In *Our Children's Earth Foundation* v. *EPA* (No. 20–8232, S.D.N.Y.), the EPA agreed to take final action on the 2015 ozone NAAQS good neighbor SIP submission from New York by April 30, 2022; however, if the EPA proposes to disapprove New York's SIP submission and proposes a replacement FIP by February 28, 2022, then EPA's deadline to take final action on New York's SIP submission is extended to December 30, 2022.

Continued

promulgate 2015 ozone NAAQS good neighbor FIPs for these same states, as well as California, Nevada, and Wyoming, but will not finalize a FIP for any of these states unless and until the EPA formally finalizes disapprovals of their SIP submittals or, in the event that any of these states withdraw their good neighbor SIP submissions after this proposal, makes a finding of failure to submit.[76] *See* CAA section 110(c).

Additionally, the EPA has taken action that has triggered EPA's obligation under CAA section 110(c) to promulgate FIPs addressing the good neighbor provision for some other states. On December 5, 2019, the EPA published a rule finding that seven states (Maine, New Mexico, Pennsylvania, Rhode Island, South Dakota, Utah, and Virginia) failed to submit or otherwise make complete submissions that address the requirements of CAA section 110(a)(2)(D)(i)(I) for the 2015 ozone NAAQS.[77] This finding triggered a 2-year deadline for the EPA to issue FIPs to address the good neighbor provision for these states by January 6, 2022. As the EPA has subsequently received and taken final action to approve good neighbor SIPs from Maine, Rhode Island, and South Dakota,[78] the EPA currently has authority under the December 5, 2019, finding of failure to submit to issue FIPs for New Mexico, Pennsylvania, Utah, and Virginia. In this proposal, EPA is issuing proposed FIP requirements for Pennsylvania, Utah, and Virginia.[79]

C. Other CAA Authorities for This Action

1. Correction of EPA's Determination Regarding Delaware's SIP Submission and Its Impact on EPA's FIP Authority for Delaware

In 2020, the EPA approved an infrastructure SIP submission from Delaware for the 2015 ozone NAAQS, which in part addressed the good neighbor provision at CAA section 110(a)(2)(D)(i)(I).[80] The EPA concluded that, based on the modeling results presented in a 2018 March memorandum and using a 2023 analytic year, Delaware's largest impact on any potential downwind nonattainment or maintenance receptor was less than 1 percent of the NAAQS.[81] As a result, the EPA found that Delaware would not significantly contribute to nonattainment or interfere with maintenance in any other state.[82] Therefore, the EPA approved the portion of Delaware's infrastructure SIP that addressed CAA section 110(a)(2)(D)(i)(I) for the 2015 ozone NAAQS.

Subsequent to the release of the modeling data shared in the March 2018 memorandum and EPA's approval of Delaware's 2015 ozone NAAQS good neighbor SIP submission, the EPA performed updated modeling, as described in Section V of this proposed rule. The data from this updated air quality modeling now show that Delaware is projected to contribute more than 1 percent of the NAAQS to downwind receptors in Bristol, Pennsylvania, in the 2023 analytic year.[83] Therefore, in light of the modeling data, EPA is proposing to find that its approval of Delaware's 2015 ozone NAAQS infrastructure SIP submission, with regard only to the portion addressing the good neighbor provision at CAA section 110(a)(2)(D)(i)(I), was in error. Section 110(k)(6) of the CAA gives the Administrator authority, without any further submission from a state, to revise certain prior actions, including actions to approve SIPs, upon determining that those actions were in error.[84] The modeling data demonstrate that EPA's prior conclusion that Delaware will not significantly contribute to nonattainment or interfere with maintenance in any other state in the 2023 analytic year was incorrect, which means that EPA's approval of Delaware's good neighbor SIP submission was in error.

Therefore, the EPA proposes to correct the error in Delaware's good neighbor SIP approval. This error correction under CAA section 110(k)(6) would revise the approval of the portion of Delaware's 2015 ozone NAAQS infrastructure SIP that addresses CAA section 110(a)(2)(D)(i)(I) to a disapproval and rescind any statements that the portion of Delaware's infrastructure SIP submission that addresses CAA section 110(a)(2)(D)(i)(I) satisfies the requirements of the good neighbor provision. The EPA is not proposing to correct the elements of Delaware's 2015 ozone NAAQS infrastructure SIP that do not address CAA section 110(a)(2)(D)(i)(I).

As discussed in greater detail in the sections that follow, the EPA is proposing to determine that there are additional emissions reductions that are required for Delaware to satisfy its good neighbor obligations for the 2015 ozone NAAQS. The analysis on which the EPA proposes this conclusion for Delaware is the same, regionally consistent analytical framework on which the Agency proposes FIP action for the other states included in this proposal. The Agency recognizes that it is possible, based on updated information for the final rule—as applied within a regionally consistent analytical framework—that Delaware (or other states for which the EPA proposes FIPs in this action) may be found to have no further interstate transport obligation for the 2015 ozone NAAQS. If such a circumstance were to occur, the EPA anticipates that it would not finalize this proposed error correction or may modify the error correction such that the approval of Delaware's portion of the SIP as it relates to its good neighbor obligations may be affirmed.

Ohio, Wisconsin). EPA has not yet proposed action on interstate transport SIPs submitted by California, Nevada, Utah, and Wyoming.

[76] See the document titled ''Status of CAA Section 110(a)(2)(D)(i)(I) SIP Submissions for the 2015 Ozone NAAQS for States Covered by the Proposed Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standards,'' included in the docket for this rulemaking, for additional information on EPA's statutory authorities for this proposed rule.

[82] *Id.* at 17. Based on the 2023 modeling from the 2018 memorandum, Delaware was expected in 2023 to have a 0.40 ppb impact on a potential nonattainment receptor in Fairfield, Connecticut (Site ID 90019003) and a 0.38 ppb impact at a potential maintenance receptor in Queens, New York (Site ID 360810124).

[83] The contribution from Delaware in 2023 to the receptor in Bristol, Pennsylvania, is 1.36 ppb.

[84] *See, e.g.,* 86 FR 23054, 23068 (error correcting prior approval of Kentucky's transport SIP submission for the 2008 ozone NAAQS to a disapproval and simultaneously promulgating FIP on the basis of the *Wisconsin* and *New York* decisions remanding CSAPR Update and vacating CSAPR Close-Out and new information establishing Kentucky was linked to downwind receptors).

2. Application of Rule in Indian Country and Necessary or Appropriate Finding

The EPA proposes that this rule will be applicable in all areas of Indian country (as defined at 18 U.S.C. 1151) within the covered geography of the proposal, as defined below. Currently, certain areas of Indian country within the geography of the proposal are subject to state implementation planning authority. Other areas of Indian country within that geography would be subject to tribal planning authority, although none of the relevant tribes have as yet sought eligibility to administer a tribal plan to implement the good neighbor provision.[85] As described later, the EPA is proposing to include all areas of Indian country within the covered geography, notwithstanding whether those areas are currently subject to a state's implementation planning authority or the potential planning authority of a tribe.

With respect to areas of Indian country not currently subject to a state's implementation planning authority—*i.e.,* Indian reservation lands (with the partial exception of reservation lands located in the State of Oklahoma, as described further below) and other areas of Indian country over which the EPA or a tribe has demonstrated that a tribe has jurisdiction—the EPA here proposes a ''necessary or appropriate'' finding that direct federal implementation of the rule's requirements is warranted under CAA section 301(d)(4) and 40 CFR 49.11(a) (the areas of Indian country subject to this finding are referred to later as the 301(d) FIP areas). Indian Tribes may, but are not required to, submit tribal plans to implement CAA requirements, including the good neighbor provision. Section 301(d) of the CAA and 40 CFR part 49 authorize the Administrator to treat an Indian Tribe in the same manner as a state (*i.e.,* TAS) for purposes of developing and implementing a tribal plan implementing good neighbor obligations. *See* 40 CFR 49.3; *see also* ''Indian Tribes: Air Quality Planning and Management,'' hereafter ''Tribal Authority Rule,'' (63 FR 7254, February 12, 1998). The EPA is authorized to directly implement the good neighbor provision in the 301(d) FIP areas when it finds, consistent with the authority of CAA section 301—which the EPA has exercised in 40 CFR 49.11—that it is necessary or appropriate to do so.[86]

The EPA proposes in this action to find that it is both necessary and appropriate to regulate all new and existing EGU and non-EGU sources meeting the applicability criteria set forth in this proposed rule in all of the 301(d) FIP areas that are located within the geographic scope of coverage of the rule. For purposes of this proposed finding, the geographic scope of coverage of the rule means the areas of the United States encompassed within the borders of the states EPA has determined to be linked at Steps 1 and 2 of the 4-step interstate transport framework.[87] For EGU applicability criteria, *see* Section VII.B of this proposed rule; for non-EGU applicability criteria, *see* Section VII.C of this proposed rule. To EPA's knowledge, only one existing EGU or non-EGU source is located within the 301(d) FIP areas: The Bonanza Power Plant, an EGU source, located on the Uintah and Ouray Reservation, geographically located within the borders of Utah.

This proposed finding is consistent with EPA's prior good neighbor rules. In prior rulemakings under the good neighbor provision, the EPA has included all areas of Indian country within the geographic scope of those FIPs, such that any new or existing sources meeting the rules' applicability criteria would be subject to the rule irrespective of whether subject to state or tribal underlying CAA planning authority. In CSAPR, the CSAPR Update, and the Revised CSAPR Update, the scope of the emissions trading programs established for EGUs extended to cover all areas of Indian country located within the geographic boundaries of the covered states. In these rules, at the time of their promulgation, no existing units were located in the covered areas of Indian country; under the general applicability criteria of the trading programs, however, any new sources locating in such areas would become subject to the programs. Thus, EPA established a separate allowance allocation that would be available for any new units locating in any of the relevant areas of Indian country. *See, e.g.,* 76 FR at 48293 (describing the CSAPR methodology of allowance allocation under the ''Indian country new unit set-aside'' provisions); *see also id.* at 48217 (explaining EPA's source of authority for directly regulating in relevant areas of Indian country as necessary or appropriate). Further, in any action in which the EPA subsequently approved a state's SIP submittal to partially or wholly replace the provisions of a CSAPR FIP, EPA has clearly delineated that it will continue to administer the Indian country new unit set aside for sources in any areas of Indian country geographically located within a state's borders and not subject to that state's CAA planning authority, and the state may not exercise jurisdiction over any such sources. *See, e.g.,* 82 FR 46674, 46677 (October 6. 2017) (approving Alabama's SIP submission establishing a state CSAPR trading program for ozone season NO_X, but providing, ''The SIP is not approved to apply on any Indian reservation land or in any other area where EPA or an Indian tribe has demonstrated that a tribe has jurisdiction.'').

In this proposed rule, the EPA proposes to take an approach similar to the prior CSAPR rulemakings with respect to regulating sources in the 301(d) FIP areas.[88] The EPA believes this approach is necessary and appropriate for several reasons. First, the purpose of this rule is to address the

[85] We note that, consistent with EPA's prior good neighbor actions in California, the regulatory ozone monitor located on the Morongo Band of Mission Indians (''Morongo'') reservation is a projected downwind receptor in 2023. *See* monitoring site 060651016 in Table V.D–1. We also note that the Temecula, California regulatory ozone monitor is a projected downwind receptor in 2023 and in past regulatory actions has been deemed representative of air quality on the Pechanga Band of Luiseño Indians (''Pechanga'') reservation. *See, e.g., Approval of Tribal Implementation Plan and Designation of Air Quality Planning Area; Pechanga Band of Luiseño Mission Indians,* 80 FR 18120, at 18121–18123 (April 3, 2015); *see also* monitoring site 060650016 in Table V.D–1. The presence of receptors on, or representative of, the Morongo and Pechanga reservations does not trigger obligations for the Morongo and Pechanga Tribes. Nevertheless, these receptors are relevant to EPA's assessment of any linked upwind states' good neighbor obligations. *See, e.g., Approval and Promulgation of Air Quality State Implementation Plans; California; Interstate Transport Requirements for Ozone, Fine Particulate Matter, and Sulfur Dioxide,* 83 FR 65093 (December 19, 2018). Under 40 CFR 49.4(a), tribes are not subject to the specific plan submittal and implementation deadlines for NAAQS-related requirements, including deadlines for submittal of plans addressing transport impacts.

[86] *See Arizona Pub. Serv. Co.* v. *U.S. E.P.A.,* 562 F.3d 1116, 1125 (10th Cir. 2009) (stating that 40 CFR 49.11(a) ''provides the EPA discretion to determine what rulemaking is necessary or appropriate to protect air quality and requires the EPA to promulgate such rulemaking''); *Safe Air For Everyone* v. *U.S. Env't Prot. Agency,* No. 05–73383, 2006 WL 3697684, at *1 (9th Cir., Dec. 15, 2006) (''The statutes and regulations that enable EPA to regulate air quality on Indian reservations provide EPA with broad discretion in setting the content of such regulations.'').

[87] With respect to any non-EGU sources located in the 301(d) FIP areas, the geographic scope of coverage of this proposed rule does not include those states for which EPA proposes to find, based on air quality modeling, that no further linkage exists by the 2026 analytic year at Steps 1 and 2. The states no longer projected to be linked in 2026 are Alabama, Delaware, and Tennessee.

[88] *See* Section VII.B.9 of this action for a discussion of revisions that are proposed in this rulemaking regarding the point in the allowance allocation process at which the EPA would establish set-asides of allowances for units in Indian country not subject to a state's CAA implementation planning authority.

interstate transport of ozone on a national scale, and the technical record establishes that the nonattainment and maintenance receptors located throughout the country are impacted by sources of ozone pollution on a broad geographic scale. The upwind regions associated with each receptor typically span at least two, and often far more, states. Within the broad upwind region covered by this proposal, the EPA proposes to apply—consistent with the methodology of allocating upwind responsibility in prior transport rules going back to the NO_X SIP Call—a uniform level of control stringency. (*See* Section VI of this proposed rule for a discussion of EPA's determination of control stringency for this proposal.) Within this approach, consistency in rule requirements across all jurisdictions is vital in ensuring the remedy for ozone transport is, in the words of the Supreme Court, ''efficient and equitable,'' 572 U.S. 489, 519. In particular, as the Supreme Court found in *EME Homer City Generation,* allocating responsibility through uniform levels of control across the entire upwind geography is ''equitable'' because, by imposing uniform cost thresholds on regulated States, EPA's rule subjects to stricter regulation those States that have done relatively less in the past to control their pollution. Upwind States that have not yet implemented pollution controls of the same stringency as their neighbors will be stopped from free riding on their neighbors' efforts to reduce pollution. They will have to bring down their emissions by installing devices of the kind in which neighboring States have already invested. *Id.*

In the context of addressing regional-scale ozone transport in this proposal, a uniform level of stringency that extends to and includes the 301(d) FIP areas geographically located within the boundaries of the linked upwind states carries significant force. Failure to include all such areas within the scope of the rule creates a significant risk that these areas may be targeted for the siting of facilities emitting ozone-precursor pollutants, in order to avoid the regulatory costs that would be imposed under this proposed rule in the surrounding areas of state jurisdiction. Electricity generation or the production of other goods and commodities may become more cost-competitive at any EGUs or non-EGUs not subject to the rule but located in a geography where all surrounding facilities in the same industrial category are subject to the rule. For instance, the affected EGU source located on the Uintah and Ouray Reservation of the Ute Tribe is in an area that is interconnected with the western electricity grid and is owned and operated by an entity that generates and provides electricity to customers in several states. It is both necessary and appropriate, in EPA's view, to avoid creating, via this proposed rule, a structure of incentives that may cause generation or production—and the associated NO_X emissions—to shift into the 301(d) FIP areas to escape regulation needed to eliminate interstate transport under the good neighbor provision.

The EPA believes it is appropriate to propose direct federal implementation of the proposed rule's requirements in the 301(d) FIP areas at this time rather than at a later date. Tribes have the opportunity to seek TAS and to undertake tribal implementation plans under the CAA. To date, the one tribe which could develop and seek approval of a tribal implementation plan to address good neighbor obligations with respect to an existing EGU in the 301(d) FIP areas for the 2015 ozone NAAQS (or for any other NAAQS), the Ute Indian Tribe of the Uintah and Ouray Reservation, has not expressed an intent to do so. Nor has the EPA heard such intentions from any other tribe, and it would not be reasonable to expect tribes to undertake that planning effort, particularly when no existing sources are currently located on their lands. Further, the EPA is mindful that under court precedent, the EPA and states generally bear an obligation to fully implement any required emissions reductions to eliminate significant contribution under the good neighbor provision as expeditiously as practicable and in alignment with downwind areas' attainment schedule under the Act. As discussed in Section VII.A of this proposed rule, the EPA anticipates implementing certain required emissions reductions by the 2023 ozone season, the last full ozone season before the 2024 Moderate area attainment date, and other key additional required emissions reductions by the 2026 ozone season, the last full ozone season before the 2027 Serious area attainment date. Absent this proposed federal implementation plan in the 301(d) FIP areas, NO_X emissions from any existing or new EGU or non-EGU sources located in, or locating in, the 301(d) FIP areas within the covered geography of the rule would remain unregulated and could potentially increase. This would be inconsistent with EPA's overall goal of aligning good neighbor obligations with the downwind areas' attainment schedule and to achieve emissions reductions as expeditiously as practicable.

Further, the EPA recognizes that Indian country, including the 301(d) FIP areas, is often home to communities with environmental justice concerns, and these communities may bear a disproportionate level of pollution burden as compared with other areas of the United States. EPA's draft Strategic Plan for Fiscal Year 2022–2026 [89] includes an objective to promote environmental justice at the Federal, Tribal, state, and local levels and states: ''Integration of environmental justice principles into all EPA activities with Tribal governments and in Indian country is designed to be flexible enough to accommodate EPA's Tribal program activities and goals, while at the same time meeting the Agency's environmental justice goals.'' By including all areas of Indian country within the covered geography of the rule, the EPA is advancing environmental justice, lowering pollution burdens in such areas, and preventing the potential for ''pollution havens'' to form in such areas as a result of facilities seeking to locate there to avoid the requirements that would otherwise apply outside of such areas under this proposed rule.

Therefore, in order to ensure timely alignment of all needed emissions reductions with the larger timetable of this proposed rule, to ensure equitable distribution of the upwind pollution reduction obligation across all upwind jurisdictions, to avoid perverse economic incentives to locate sources of ozone-precursor pollution in the 301(d) FIP areas, and to deliver greater environmental justice to tribal communities in line with Executive Order 13985: Advancing Racial Equity and Support for Underserved Communities Through the Federal Government,[90] EPA proposes to find it both necessary and appropriate that all existing and new EGU and non-EGU sources that are located in the 301(d) FIP areas within the geographic boundaries of the covered states, and which would be subject to this rule if located within areas subject to state CAA planning authority, should be included in this rule. The EPA proposes this finding under section 301(d)(4) of the Act and 40 CFR 49.11. Further, in order to avoid ''unreasonable delay'' in

[89] *https://www.epa.gov/system/files/documents/2021-10/fy-2022-2026-epa-draft-strategic-plan.pdf*

[90] Executive Order 13985 (January 20, 2021): *https://www.whitehouse.gov/briefing-room/presidential-actions/2021/01/20/executiveorder-advancing-racial-equity-and-support-for-underserved-communities-through-the-federal-government/.*

promulgating this FIP, as required under section 49.11, the EPA believes it is appropriate to make this proposed finding now, in order to align emissions reduction obligations for any covered new or existing sources in the 301(d) FIP areas with the larger schedule of reductions under this proposed rule. Because all other covered EGU and non-EGU sources within the geography of this proposed rule would be subject to emissions reductions of uniform stringency beginning in the 2023 ozone season, and as necessary to fully and expeditiously address good neighbor obligations for the 2015 ozone NAAQS, there is little benefit to be had by not proposing to include the 301(d) FIP areas in this rule now and a potentially significant downside to not doing so.

The Agency recognizes that Tribal governments may still choose to seek TAS to develop a Tribal plan with respect to the obligations under this proposed rule, and this proposed determination does not preclude the tribes from taking such actions. The EPA will continue to consult with the government of the Ute Indian Tribe of the Uintah and Ouray Reservation, and any other tribe wishing to continue consultation, during the comment period for this proposal. The EPA invites comment on this proposed finding.

a. Indian Country Subject to State Implementation Planning Authority

Following the U.S. Supreme Court decision in *McGirt* v. *Oklahoma,* 140 S. Ct. 2452 (2020), the Governor of the State of Oklahoma requested approval under Section 10211(a) of the Safe, Accountable, Flexible, Efficient Transportation Equity Act of 2005: A Legacy for Users, Public Law 109–59, 119 Stat. 1144, 1937 (August 10, 2005) (''SAFETEA''), to administer in certain areas of Indian country (as defined at 18 U.S.C. 1151) the State's environmental regulatory programs that were previously approved by the EPA for areas outside of Indian country. The State's request excluded certain areas of Indian country further described later. In addition, the State only sought approval to the extent that such approval is necessary for the State to administer a program in light of *Oklahoma Dept. of Environmental Quality* v. *EPA,* 740 F.3d 185 (D.C. Cir. 2014).[91]

On October 1, 2020, the EPA approved Oklahoma's SAFETEA request to administer all the State's EPA-approved environmental regulatory programs, including the Oklahoma SIP, in the requested areas of Indian country.[92] As requested by Oklahoma, the EPA's approval under SAFETEA does not include Indian country lands, including rights-of-way running through the same, that: (1) Qualify as Indian allotments, the Indian titles to which have not been extinguished, under 18 U.S.C. 1151(c); (2) are held in trust by the United States on behalf of an individual Indian or Tribe; or (3) are owned in fee by a Tribe, if the Tribe (a) acquired that fee title to such land, or an area that included such land, in accordance with a treaty with the United States to which such Tribe was a party, and (b) never allotted the land to a member or citizen of the Tribe (collectively ''excluded Indian country lands'').

EPA's approval under SAFETEA expressly provided that to the extent EPA's prior approvals of Oklahoma's environmental programs excluded Indian country, any such exclusions are superseded for the geographic areas of Indian country covered by EPA's approval of Oklahoma's SAFETEA request.[93] The approval also provided that future revisions or amendments to Oklahoma's approved environmental regulatory programs would extend to the covered areas of Indian country (without any further need for additional requests under SAFETEA).

In a **Federal Register** notice published on February 22, 2022 (87 FR 9798), the EPA proposed to disapprove the portion of an Oklahoma SIP submittal pertaining to the state's interstate transport obligations under CAA section 110(a)(2)(D)(i)(I) for the 2015 ozone NAAQS. Consistent with the D.C. Circuit's decision in *ODEQ* v. *EPA* and with EPA's October 1, 2020 SAFETEA approval, if this disapproval is finalized as proposed, EPA will have authority under CAA section 110(c) to promulgate a FIP as needed to address the disapproved aspects of the State's good neighbor SIP submittal.[94] In accordance with the discussion above, EPA's FIP authority in this circumstance would extend to all Indian country in Oklahoma, other than the excluded Indian country lands, as described previously.[95] Because—per the State's request under SAFETEA—EPA's October 1, 2020 approval does not displace any SIP authority previously exercised by the State under the CAA as interpreted in *ODEQ* v. *EPA,* EPA's FIP authority under CAA section 110(c) would also apply to any Indian allotments or dependent Indian communities located outside of an Indian reservation over which there has been no demonstration of tribal authority. EPA's FIP authority under CAA section 110(c) would similarly apply to Indian allotments or dependent Indian communities located outside of an Indian reservation over which there has been no demonstration of tribal authority located in any other state within the geographic scope of this proposed rule.

In light of the relevant legal authorities discussed above regarding the scope of the State of Oklahoma's regulatory jurisdiction under the CAA, the EPA has FIP authority under CAA section 110(c) with respect to all Indian country in Oklahoma other than excluded Indian country lands. To the extent any change occurs in the scope of Oklahoma's SIP authority in Indian country before the finalization of this proposed rule, such a change may affect the ability of the Agency to exercise the FIP authority provided under section 110(c) of the Act.[96] In that eventuality,

[91] In *ODEQ* v. *EPA,* the D.C. Circuit held that under the CAA, a state has the authority to implement a SIP in non-reservation areas of Indian country in the state, where there has been no demonstration of tribal jurisdiction. Under the D.C. Circuit's decision, the CAA does not provide authority to states to implement SIPs in Indian reservations. *ODEQ* did not, however, substantively address the separate authority in Indian country provided specifically to Oklahoma under SAFETEA. That separate authority was not invoked until the State submitted its request under SAFETEA, and was not approved until EPA's decision, described in this section, on October 1, 2020.

[92] Available in the docket for this rulemaking.

[93] EPA's prior approvals relating to Oklahoma's SIP frequently noted that the SIP was not approved to apply in areas of Indian country (consistent with the D.C. Circuit's decision in *ODEQ* v. *EPA*) located in the state. *See, e.g.,* 85 FR 20178, 20180 (April 10, 2020). Such prior expressed limitations are superseded by EPA's approval of Oklahoma's SAFETEA request.

[94] The antecedent fact that the state had the authority and jurisdiction to implement requirements under the good neighbor provision, in EPA's view, supplies the condition necessary for the Agency to exercise its FIP authority to the extent the EPA has disapproved the state's SIP submission with respect to those requirements. Under CAA section 110(c), the EPA ''stands in the shoes of the defaulting state, and all of the rights and duties that would otherwise fall to the state accrue instead to the EPA.'' *Central Ariz. Water Conservation Dist.* v. *EPA,* 990 F.2d 1531, 1541 (9th Cir. 1993).

[95] With respect to those areas of Indian country constituting ''excluded Indian country lands'' in the State of Oklahoma, as defined above, the EPA proposes to apply the same necessary or appropriate finding as set forth above with respect to all other 301(d) FIP areas within the geographic scope of coverage of the rule.

[96] On December 22, 2021, the EPA proposed to withdraw and reconsider the October 1, 2020, SAFETEA approval. *See https://www.epa.gov/ok/proposed-withdrawal-and-reconsideration-and-supporting-information.* The EPA is engaging in further consultation with tribal governments and expects to have discussions with the State of Oklahoma as part of this reconsideration. The EPA also notes that the October 1, 2020, approval is the

Continued

and to the extent any such areas would then fall more appropriately within the 301(d) FIP areas as described earlier in this section, EPA's proposed necessary or appropriate finding as set forth above with respect to all other 301(d) FIP areas within the geographic scope of coverage of the rule would then apply.

V. Analyzing Downwind Air Quality Problems and Contributions From Upwind States

A. Selection of Analytic Years for Evaluating Ozone Transport Contributions to Downwind Air Quality Problems

In this section, the EPA describes its process for selecting analytic years for air quality modeling and analyses performed to identify nonattainment and maintenance receptors and identify upwind state linkages. For this proposed rule, the EPA evaluated air quality to identify receptors at Step 1 for three analytic years: 2023, 2026, and 2032. The EPA evaluated interstate contributions to these receptors from individual upwind states at Step 2 for two of these analytic years: 2023 and 2026. In selecting these years, the EPA views 2023 and 2026, in particular, to constitute years by which key emissions reductions from EGUs and non-EGUS can be implemented ''as expeditiously as practicable.'' (The EPA explains in detail in Section VII of this proposed rule its proposed determination that the necessary emissions reductions cannot be achieved any more quickly.) In addition, these years are the last full ozone seasons before the Moderate and Serious area attainment dates for the 2015 ozone NAAQS (ozone seasons run each year from May 1–September 30). In order to demonstrate attainment by these deadlines, downwind states would be required to rely on design values calculated using ozone design values from 2021 through 2023 and 2024 through 2026, respectively. By focusing its analysis, and, potentially, achieving emissions reductions by, the last full ozone seasons before the attainment dates (*i.e.,* in 2023 or 2026), this proposed rule, if finalized, can assist the downwind areas with demonstrating attainment or receiving extensions of attainment dates under CAA section 181(a)(5).

It would not make sense for the EPA to analyze any earlier year than 2023. EPA continues to interpret the good neighbor provision as forward-looking, based on Congress's use of the future-tense ''will'' in section 110(a)(2)(D)(i), an interpretation upheld in *Wisconsin,* 938 F.3d at 322. It would be ''anomalous,'' *id.,* for the EPA to impose good neighbor obligations in 2023 and future years based solely on finding that ''significant contribution'' had existed at some time in the past. *Id.*

Applying this framework in this proposal, the EPA recognizes that the 2021 Marginal area attainment date has already passed. Further, based on the timing of this proposal, it will not be possible to finalize this rulemaking before the 2022 ozone season has also passed. Thus, EPA has selected 2023 as the first appropriate future analytic year for this proposed rule because it reflects implementation of good neighbor obligations as expeditiously as practicable and coincides with the August 3, 2024, Moderate area attainment date established for the 2015 ozone NAAQS.

The EPA conducted additional analysis for the 2026 and 2032 analytic years in order to ensure a complete Step 3 analysis for future ozone transport contributions to downwind areas. These years also coincide with the last full ozone seasons before future attainment dates for the 2015 ozone NAAQS, and 2026 coincides with the ozone season by which key additional emissions reductions from EGUs and non-EGUs become available. Thus, the EPA analyzed additional years beyond 2023 to determine whether any additional emissions reductions that are impossible to obtain by the 2024 attainment date could still be necessary in order to fully address significant contribution, taking into account the 2027 Serious area attainment date and the 2033 Severe area attainment date for the 2015 ozone NAAQS. In all cases, the proposed implementation of necessary emissions reductions is as expeditiously as practicable, with all possible emissions reductions implemented by the next applicable attainment date.

The timing framework and selection of analytic years set forth above comports with the D.C. Circuit's direction in *Wisconsin* that implementing good neighbor obligations beyond the dates established for attainment may be justified on a proper showing of impossibility or necessity. *See* 938 F.3d at 320.

The remainder of this section includes information on (1) the air quality modeling platform used in support of the proposed rule with a focus on the base year and future year base case emissions inventories, (2) the method for projecting design values in 2023, 2026, and 2032, and (3) the approach for calculating ozone contributions from upwind states. The Agency also provides the design values for nonattainment and maintenance receptors and the predicted interstate contributions that are at or above the 1 percent of the NAAQS screening threshold. The 2016 base period and 2023, 2026, and 2032 future design values and contributions for all ozone monitoring sites are provided in the docket for this proposed rule. The Air Quality Modeling Technical Support Document (AQM TSD) in the docket for this proposed rule contains more detailed information on the air quality modeling aspects of this rule.

B. Overview of Air Quality Modeling Platform

The EPA used version 2 of the 2016-based modeling platform for the air quality modeling for this proposed rule. This modeling platform includes 2016 base year emissions from anthropogenic and natural sources and 2016 meteorology. The platform also includes anthropogenic emissions projections for 2023, 2026, and 2032. The emissions data contained in this platform represent an update to the 2016 version 1 inventories that were developed by the EPA, the Multi-Jurisdictional Organizations (MJOs), and state and local air agencies as part of the Emissions Inventory Collaborative Process.

The air quality modeling for this proposal was performed for a modeling region (*i.e.,* modeling domain) that covers the contiguous 48 states using a horizontal resolution of 12 x 12 km. The EPA used the CAMx version 7.10 for air quality modeling since this was the most recent version of CAMx available at the time the air quality modeling was performed.[97] Additional information on the 2016-based air quality modeling platform can be found in the AQM TSD.

C. Emissions Inventories

The EPA developed emissions inventories for this proposal, including emissions estimates for EGUs, non-EGU point sources, stationary nonpoint sources, onroad mobile sources, nonroad mobile sources, other mobile sources, wildfires, prescribed fires, and biogenic emissions that are not the direct result of human activities. EPA's air quality modeling relies on this comprehensive set of emissions inventories because emissions from multiple source categories are needed to model ambient air quality and to facilitate comparison of model outputs with ambient measurements.

subject of a pending challenge in federal court. *Pawnee Nation of Oklahoma* v. *Regan,* No. 20–9635 (10th Cir.).

[97] Ramboll Environment and Health, January 2021, *http://www.camx.com.*

To prepare the emissions inventories for air quality modeling, the EPA processed the emissions inventories using the Sparse Matrix Operator Kernel Emissions (SMOKE) Modeling System version 4.8.1 to produce the gridded, hourly, speciated, model-ready emissions for input to the air quality model. Additional information on the development of the emissions inventories and on data sets used during the emissions modeling process are provided in the TSD titled, ''Preparation of Emissions Inventories for the 2016v2 North American Emissions Modeling Platform,'' hereafter known as the ''Emissions Modeling TSD.'' This TSD is available in the docket for this rule.

1. Foundation Emissions Inventory Data Sets

The 2016v2 emissions platform is comprised of data from various sources including data developed using models, methods, and source datasets that became available in calendar years 2020 and 2021, in addition to data from the Inventory Collaborative 2016 version 1 (2016v1) Emissions Modeling Platform, released in October 2019. The 2016v1 platform was developed through a national collaborative effort between the EPA and state and local agencies along with MJOs and included emissions inventories for the years 2016, 2023, and 2028. For this proposed rule, emissions inventories were developed for the years 2016, 2023, 2026, and 2032 that represent changes in activity data and of predicted emissions reductions from on-the-books actions, planned emissions control installations, and promulgated federal measures that affect anthropogenic emissions.[98] The 2016 emissions inventories for the U.S. include data derived from the 2017 National Emissions Inventory (2017NEI) and some data derived from the 2014 National Emissions Inventory (NEI), version 2 (2014NEIv2). All of the inventory sectors were updated to better represent the year 2016 through the incorporation of 2016-specific state and local data along with nationally applied adjustment methods. The following sections provide an overview of the construct of the 2016v2 emissions and projections.

2. Development of Emissions Inventories for EGUs

Annual NO_X and SO_2 emissions for EGUs in the 2016 base year inventory are based primarily on data from continuous emissions monitoring systems (CEMS) and other monitoring systems allowed for use by qualifying units under 40 CFR part 75, with other EGU pollutants estimated using emissions factors and annual heat input data reported to the EPA. For EGUs not reporting under part 75, the EPA used data submitted to the NEI and the 2016v1 platform by the states. Emissions data for EGUs that did not have data provided for the year 2016 were pulled forward from data submitted for the 2014 NEI. The Air Emissions Reporting Rule, (80 FR 8787; February 19, 2015), requires that Type A point sources large enough to meet or exceed specific thresholds for emissions be reported to the EPA every year, while the smaller Type B point sources must only be reported to EPA every 3 years.

The EPA projected future 2023, 2026, and 2032 baseline EGU emissions using the version 6—Summer 2021 Reference Case of the Integrated Planning Model (IPM). IPM, developed by ICF Consulting, is a state-of-the-art, peer-reviewed, multi-regional, dynamic, deterministic linear programming model of the contiguous U.S. electric power sector. It provides forecasts of least cost capacity expansion, electricity dispatch, and emissions control strategies while meeting energy demand and environmental, transmission, dispatch, and reliability constraints. The EPA has used IPM for over two decades, including all prior implemented CSAPR rulemakings, to better understand power sector behavior under future business-as-usual conditions and to evaluate the economic and emissions impacts of prospective environmental policies. The model is designed to reflect electricity markets as accurately as possible. The EPA uses the best available information from utilities, industry experts, gas and coal market experts, financial institutions, and government statistics as the basis for the detailed power sector modeling in IPM. The model documentation provides additional information on the assumptions discussed here as well as all other model assumptions and inputs.[99]

The IPM version 6—Summer 2021 Reference Case incorporated recent updates through the Summer of 2021 to account for updated federal and state environmental regulations (including Renewable Portfolio Standards (RPS), Clean Energy Standards (CES) and other state mandates), fleet changes (committed EGU retirements and new builds), electricity demand, technology cost and performance assumptions from recent data (for renewables adopting from National Renewable Energy Lab (NREL's) Annual Technology Baseline 2020 and for fossil sources from U.S. Energy Information Agency's (EIA) Annual Energy Outlook (AEO) 2020. Natural gas and coal price projections reflect data developed in Fall 2020. The inventory of EGUs provided as an input to the model was the National Electric Energy Data System (NEEDS) Summer 2021 version and is available on EPA's website.[100] This version of NEEDS reflects announced retirements and under construction new builds known as of early summer 2021. This projected base case accounts for the effects of the finalized Mercury and Air Toxics Standards rule, CSAPR, the CSAPR Update, the Revised CSAPR Update, New Source Review settlements, the final Effluent Limitation Guidelines (ELG) Rule, the Coal Combustion Residual (CCR) Rule, and other on-the-books federal and state rules (including renewable energy tax credit extensions from the Consolidated Appropriations Act of 2021) through early 2021 impacting SO_2, NO_X, directly emitted particulate matter, CO_2, and power plant operations. It also includes final actions the EPA has taken to implement the Regional Haze Rule and BART requirements. IPM has projected output years for 2023 and 2025. IPM year 2025 outputs were adjusted for known retirements to be reflective of year 2026, and IPM year 2030 outputs were used for the year 2032 as is specified by the mapping of IPM output years to specific years.

Additional 2023 through 2026 EGU emissions baseline levels were developed through engineering analytics as an alternative approach that did not involve IPM. The EPA developed this inventory for use in Step 3 of this final rule, where it determines emissions reduction potential and corresponding state-level emissions budgets. IPM includes optimization and perfect foresight in solving for least cost dispatch. Given that this final rule will likely become effective immediately prior to the start of the 2023 ozone season, the EPA is adopting a similar approach to the CSAPR Update and the

[98] Biogenic emissions and emissions from wildfires and prescribed fires were held constant between 2016 and the future years because (1) these emissions are tied to the 2016 meteorological conditions and (2) the focus of this rule is on the contribution from anthropogenic emissions to projected ozone nonattainment and maintenance.

[99] Detailed information and documentation of EPA's Base Case, including all underlying assumptions, data sources, and architecture parameters can be found on EPA's website at: *https://www.epa.gov/airmarkets/epas-power-sector-modeling-platform-v6-using-ipm-summer-2021-reference-case.*

[100] *Available at https://www.epa.gov/airmarkets/national-electric-energy-data-system-needs-v6.*

Revised CSAPR Update where it relied on IPM in a relative way in Step 3 to avoid overstating optimization and dispatch decisions in state-emissions budget quantification that may not be possible in a short time frame. The EPA does this by using the difference in emissions rate observed between IPM runs with and without the cost threshold applied, rather than using absolute values. In both the CSAPR Update and in this rule at Step 3, EPA complemented that projected IPM EGU outlook with historical (*e.g.,* engineering analytics) perspective based on historical data that only factors in known changes to the fleet. This 2023 engineering analytics data set is described in more detail in the Ozone Transport Policy Analysis Proposed Rule TSD and corresponding Appendix A: State Emissions Budgets Calculations and Underlying Data. The Engineering Analysis used in Step 3 is also discussed further in Section VII.B of this proposed rule.

Both IPM and the Engineering Analytics tools are valuable for estimating future EGU emissions and examining the cone of uncertainty around any future sector-level inventory estimate. A key difference between the two tools is that IPM reflects both announced and projected changes in fleet operation, whereas the Engineering Analytics tool only reflects announced changes. By not including projected changes that are anticipated in response to market forces and fleet trends, the Engineering Analysis is deliberately conservative in its estimate of change in the power sector. Throughout all of the CSAPR rules to date, and prior interstate transport actions, the EPA has used IPM at Steps 1 and 2 as it is best suited for projecting emissions in an airshed, at projecting emissions for time horizons more than a few years out (for which changes would not yet be announced and thus projecting changes is critical), and for scenarios where the assumed change in emissions is not being codified into a state emissions reduction requirement. Using IPM at Steps 1 and 2 helps the EPA avoid overstating future year receptor values (Step 1) and future year linkages (Step 2) by reflecting reductions anticipated to occur within the airshed in the relevant timeframe.

Engineering analytics has been a useful tool for Step 3 state-level emissions reduction estimates in CSAPR rulemaking, because at that step EPA is dealing with more geographic granularity (state-level as opposed to regional air shed), more near-term (as opposed to medium-term) assessments, and scenarios where reduction estimates are codified into regulatory requirements. Using the Engineering Analytics tool at this step ensures that the EPA is not codifying into the base case, and consequently into state emissions budgets, changes in the power sector that are merely modeled to occur rather than announced by real-world actors.

Finally, both in the Revised CSAPR Update and in this rule, the EPA was able to use the Air Quality Assessment Tool to verify that regardless of which EGU inventory is used, the 2023 starting geography of the program is not impacted. In other words, regardless of whether a stakeholder takes a more comprehensive view of the EGU future (IPM) or a more conservative view of change in the EGU fleet (Engineering Analysis) the starting geography would be the same. This finding is consistent with the observation that EGUs are now less than 10% of the total ozone-season NO_X inventory and the degree of near-term difference between the IPM and Engineering Analytic regional projections is relatively small on the regional level. While the EPA continues to believe that IPM is best suited for Step 1 and Step 2, and engineering analytics is best suited for Step 3 efforts in this rulemaking, the Agency is requesting comment on the EGU emissions inventory most reasonable for Step 1 and Step 2 in the analysis. The Ozone Transport Policy Analysis Proposed Rule TSD contains data on 2023 and 2026 AQ impacts of each dataset.

3. Development of Emissions Inventories for Non-EGU Point Sources

The updates to the non-EGU point source emissions include a few sources being moved to the EGU inventory and additional control efficiency information for the year 2016. In the 2016v2 platform, some non-EGU point source emissions were based on data submitted for 2016, others were projected from 2014 to 2016, and the emissions for any remaining small sources were kept at 2014 levels. Prior to air quality modeling, the emissions inventories were processed into a format that is appropriate for the air quality model to use. The future year non-EGU point inventories were grown from 2016 to the future years using factors based on the AEO 2021 except for limited cases where errors were identified with the AEO 2021 data in which case data from AEO 2020 were used. The future year inventories reflect emissions reductions due to national and local rules, control programs, plant closures, consent decrees, and settlements. Reductions from several Maximum Achievable Control Technology and National Emissions Standards for Hazardous Air Pollutants (NESHAP) standards are included. Projection approaches for corn ethanol and biodiesel plants, refineries and upstream impacts represent requirements pursuant to the Energy Independence and Security Act of 2007 (EISA).

Aircraft emissions and ground support equipment at airports are represented as point sources and are based on adjustments to emissions in the January 2021 version of the 2017 NEI (see *https://www.epa.gov/air-emissions-inventories/2017-national-emissions-inventory-nei-data* for data and a TSD). A notable update in the January 2021 version of the 2017 NEI as compared to the April 2020 version was a correction to some double counting of some airport emissions. This correction is incorporated into the inventories for this proposed rule. The EPA developed and applied factors to adjust the 2017 airport emissions to 2016, 2023, 2026, and 2032 based on activity growth projected by the Federal Aviation Administration 2019 Terminal Area Forecast [101] system, the latest available version at the time the factors were developed.

Emissions at rail yards were represented as point sources. The 2016 rail yard emissions are largely consistent with the 2017 NEI rail yard emissions. The 2016 and 2023 rail yard emissions were developed through the 2016v1 Inventory Collaborative process, with the 2026 emissions interpolated between the 2023 and 2028 emissions from 2016v1 rail yard emissions were interpolated from the 2016 and 2023 emissions. Class I rail yard emissions were projected based on the AEO freight rail energy use growth rate projections for 2016, 2023, and 2032 with the fleet mix assumed to be constant throughout the period.

Point source oil and gas emissions for 2016 were based on the 2016v1 point inventory except that an inventory generated by the Western Regional Air Partnership (WRAP) [102] was used for the states of Colorado, Montana, New Mexico, North Dakota, South Dakota, Utah, and Wyoming. The 2016 oil and gas inventories were first projected to 2019 values based on actual production data, and those 2019 emissions were projected to 2023, 2026, and 2032 using regional projection factors by product type based on AEO 2021 projections. NO_X and VOC reductions that are co-

[101] *https://www.faa.gov/data_research/aviation/taf/.*

[102] *http://www.wrapair2.org/pdf/WRAP_OGWG_Report_Baseline_17Sep2019.pdf.*

benefits to the NESHAP and New Source Performance Standards (NSPS) for Stationary Reciprocating Internal Combustion Engines (RICE) are reflected for select source categories. In addition, Natural Gas Turbines and Process Heaters NSPS NO_X controls and NSPS Oil and Gas VOC controls [103] are reflected for select source categories. The WRAP future year inventory was used in WRAP states in all future years.[104]

4. Development of Emissions Inventories for Onroad Mobile Sources

Onroad mobile sources include exhaust, evaporative, and brake and tire wear emissions from vehicles that drive on roads, parked vehicles, and vehicle refueling. Emissions from vehicles using regular gasoline, high ethanol gasoline, diesel fuel, and electric vehicles were represented, along with buses that used compressed natural gas. The EPA developed the onroad mobile source emissions for states other than California using EPA's Motor Vehicle Emissions Simulator (MOVES). MOVES3 was released in November 2020 and has been followed by some minor releases that improved the usage of the model but that do not have substantive impacts on the emissions estimates. For this proposal, MOVES3 was run using inputs provided by state and local agencies through the 2017 NEI where available, in combination with nationally available data sets to develop a complete inventory. Onroad emissions for 2016v2 were developed based on emissions factors output from MOVES3 run for the year 2016, coupled with activity data (*e.g.,* vehicle miles traveled and vehicle populations) representing the year 2016. The 2016 activity data were provided by some state and local agencies through the 2016v1 process, and the remaining activity data were derived from the 2017 NEI. The onroad emissions were computed within SMOKE by multiplying emissions factors developed using MOVES with the appropriate activity data. Onroad mobile source emissions for California were consistent with the emissions data provided by the state.

The future-year emissions estimates for onroad mobile sources represent all national control programs known at the time of modeling including rules newly added in MOVES3: The Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles (HDGHG)—Phase 2 [105] and the Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule.[106] Other finalized rules incorporated into the onroad mobile source emissions estimates include: Tier 3 Standards (March 2014), the Light-Duty Greenhouse Gas Rule (March 2013), Heavy (and Medium)-Duty Greenhouse Gas Rule (August 2011), the Renewable Fuel Standard (February 2010), the Light Duty Greenhouse Gas Rule (April 2010), the Corporate-Average Fuel Economy standards for 2008–2011 (April 2010), the 2007 Onroad Heavy-Duty Rule (February 2009), and the Final Mobile Source Air Toxics Rule (MSAT2) (February 2007). Estimates of the impacts of rules that were in effect in 2016 are included in the 2016 base year emissions at a level that corresponds to the extent to which each rule had penetrated into the fleet and fuel supply by the year 2016. Local control programs such as the California LEV III program for criteria pollutants are included in the onroad mobile source emissions.

The future year onroad emissions reflect projected changes to fuel properties and usage, along with the impact of the rules included in MOVES3 for each of the future years. MOVES was run for the years 2023, 2026, and 2032 to generate the emissions factors relevant to those years. Future year activity data for onroad mobile sources were provided by some state and local agencies, and otherwise were projected to 2023, 2026, and 2032 by first projecting the 2016 activity to year 2019 based on county level vehicle miles traveled (VMT) from the Federal Highway Administration, and then from 2019 to the future years using AEO 2021-based factors. The future year emissions were computed within SMOKE by multiplying the future year emissions factors developed using MOVES with the year-specific activity data.

5. Development of Emissions Inventories for Commercial Marine Vessels

The commercial marine vessel (CMV) emissions in the 2016 base case emissions inventory for this rule were based on those in the 2017 NEI. Factors were then applied to adjust the 2017 NEI emissions backward to represent emissions for the year 2016. The CMV emissions reflect reductions associated with the Emissions Control Area proposal to the International Maritime Organization control strategy (EPA–420–F–10–041, August 2010); reductions of NO_X, VOC, and CO emissions for new C3 engines that went into effect in 2011; and fuel sulfur limits that went into effect prior to 2016. The cumulative impacts of these rules through 2023, 2026 and 2030 [107] were incorporated into the projected emissions for CMV sources. The CMV emissions were split into emissions inventories from the larger category 3 (C3) engines, and those from the smaller category 1 and 2 (C1C2) engines. CMV emissions in California are based on emissions provided by the state. The CMV emissions are consistent with the emissions for the 2016v1 platform updated CMV emissions released by February 2020 although they include future years of 2026 and 2030 instead of 2028.

6. Development of Emissions Inventories for Other Nonroad Mobile Sources

Nonroad mobile source emissions inventories (other than CMV, locomotive, and aircraft emissions) were developed from monthly, county, and process level emissions output from MOVES3. Types of nonroad equipment include recreational vehicles, pleasure craft, and construction, agricultural, mining, and lawn and garden equipment. State-submitted emissions data for nonroad sources were used for California.

The EPA also ran MOVES3 for 2023, 2026, and 2032 to prepare nonroad mobile emissions inventories for future years. The nonroad mobile emissions control programs include reductions to locomotives, diesel engines, and recreational marine engines, along with standards for fuel sulfur content and evaporative emissions. A comprehensive list of control programs included for mobile sources is available in the Emissions Modeling TSD.

[103] On November 15, 2021, the EPA published proposed revisions to standards of performance for new, reconstructed, and modified sources and proposed revisions to emissions guidelines for existing sources in the oil and natural gas sector at 86 FR 63110. Emissions reductions from proposed federal regulatory programs are not included in EPA's baseline analyses until they have been finalized.

[104] *http://www.wrapair2.org/pdf/WRAP_OGWG_2028_OTB_RevFinalReport_05March2020.pdf.*

[105] The effect of the HDGHG Phase 2 rule on criteria pollutants is estimated in Table 5–48 of the Regulatory Impact Analysis, available from *https://nepis.epa.gov/Exe/ZyPDF.cgi/P100P7NS.PDF?Dockey=P100P7NS.PDF.*

[106] Information on the SAFE vehicles rule is available from *https://www.epa.gov/regulations-emissions-vehicles-and-engines/safer-affordable-fuel-efficient-safe-vehicles-final-rule.* Preliminary analysis by the Office of Transportation and Air Quality of the impact of this rule on criteria pollutants show impacts of less than 1 percent for VOC and no impact for NO_X.

[107] CMV emissions were projected out to 2030 instead of 2032 because that was the last year of data available in a dataset used in the projections process. The year 2030 inventories were used in the 2032 emissions case.

Line haul locomotives are also considered a type of nonroad mobile source but the emissions inventories for locomotives were not developed using MOVES3. Year 2016 and 2023 locomotive emissions were developed through the 2016v1 process and the year 2016 emissions are mostly consistent with those in the 2017 NEI. The projected locomotive emissions for 2023, 2026, and 2030[108] were developed by applying factors to the base year emissions using activity data based on AEO freight rail energy use growth rate projections along with emissions rates adjusted to account for recent historical trends.

7. Development of Emissions Inventories for Nonpoint Sources

Some emissions for stationary nonpoint sources in the 2016 base case emissions inventory come from the 2017 NEI adjusted to 2016 levels, while others are based on data from the 2014NEIv2 adjusted to reflect year 2016 more closely using factors based on changes to human population from 2014 to 2016. Stationary nonpoint sources include evaporative sources, consumer products, fuel combustion that is not captured by point sources, agricultural livestock, agricultural fertilizer, residential wood combustion, fugitive dust, and oil and gas sources. The emissions sources based on the 2017 NEI include agricultural livestock, fugitive dust, residential wood combustion, waste disposal (including composting), bulk gasoline terminals, and miscellaneous non-industrial sources such as cremation, hospitals, lamp breakage, and automotive repair shops. A new method for solvent VOC emissions was used.[109]

Where states provided the Inventory Collaborative information about projected control measures or changes in nonpoint source emissions for 2016v1 or 2016v2, those inputs were incorporated into the projected inventories for 2023, 2026, and 2032 to the extent possible. Where possible, projection factors based on the AEO were based on AEO 2021. Adjustments for state fuel sulfur content rules for fuel oil in the Northeast were included. Projected emissions for portable fuel containers reflect the impact of projection factors required by the final MSAT2 rule and the EISA, including updates to cellulosic ethanol plants, ethanol transport working losses, and ethanol distribution vapor losses.

For 2016, nonpoint oil and gas emissions inventories were developed based on a run of the 2017 NEI version of the EPA Oil and Gas Tool with data for year 2016 coupled with the WRAP inventory for production-related nonpoint oil and gas emissions in the states of Colorado, Montana, New Mexico, North Dakota, South Dakota, Utah, and Wyoming, and a California Air Resources Board-provided inventory was used for emissions in California. Nonpoint oil and gas emissions in other states and exploration-related emissions in the WRAP states were based on a run of the 2017 NEI version of the EPA Oil and Gas Tool with input data for the year 2016. The 2016 oil and gas inventories were first projected to 2019 values based on actual production data, and those 2019 emissions were projected to 2023, 2026, and 2032 using regional projection factors by product type based on AEO 2021 projections. NO_X and VOC reductions that are co-benefits to the NESHAP and NSPS for RICE are reflected for select source categories. In addition, Natural Gas Turbines and Process Heaters NSPS NO_X controls and NSPS Oil and Gas VOC controls are reflected for select source categories. The WRAP future year inventory was used in WRAP states in all future years.[110]

D. Air Quality Modeling To Identify Nonattainment and Maintenance Receptors

In this section, the Agency describes the air quality modeling and analyses performed in Step 1 to identify locations where the Agency expects there to be nonattainment or maintenance receptors for the 2015 ozone NAAQS in the 2023, 2026, and 2032 analytic future years. Where EPA's analysis shows that an area or site does not fall under the definition of a nonattainment or maintenance receptor in 2023, that site is excluded from further analysis under EPA's good neighbor framework.

In this proposed rule, the EPA is applying the same approach used in the CSAPR Update and the Revised CSAPR Update to identify nonattainment and maintenance receptors for the 2008 ozone NAAQS. *See* 86 FR 23078–79.

EPA's approach gives independent effect to both the ''contribute significantly to nonattainment'' and the ''interfere with maintenance'' prongs of section 110(a)(2)(D)(i)(I), consistent with the D.C. Circuit's direction in *North Carolina.*[111] Further, in its decision on the remand of the CSAPR from the Supreme Court in the *EME Homer City* case, the D.C. Circuit confirmed that EPA's approach to identifying maintenance receptors in the CSAPR comported with the court's prior instruction to give independent meaning to the ''interfere with maintenance'' prong in the good neighbor provision. *EME Homer City II,* 795 F.3d at 136.

In the CSAPR Update and the Revised CSAPR Update, the EPA identified nonattainment receptors as those monitoring sites that are projected to have average design values that exceed the NAAQS and that are also measuring nonattainment based on the most recent monitored design values. This approach is consistent with prior transport rulemakings, such as the NO_X SIP Call and CAIR, where the EPA defined nonattainment receptors as those areas that both currently monitor nonattainment and that the EPA projects will be in nonattainment in the future compliance year.[112]

The Agency explained in the NO_X SIP Call and CAIR and then reaffirmed in the CSAPR Update that the EPA has the most confidence in our projections of nonattainment for those counties that also measure nonattainment for the most recent period of available ambient data. The EPA separately identified maintenance receptors as those receptors that would have difficulty maintaining the relevant NAAQS in a scenario that accounts for historical variability in air quality at that receptor. The variability in air quality was determined by evaluating the ''maximum'' future design value at each receptor based on a projection of the maximum measured design value over the relevant period. The EPA interprets the projected maximum future design value to be a potential future air quality outcome consistent with the meteorology that yielded maximum measured concentrations in the ambient data set analyzed for that receptor (*i.e.,* ozone conducive meteorology). The EPA also recognizes that previously experienced meteorological conditions (*e.g.,* dominant wind direction, temperatures, and air mass patterns) promoting ozone formation that led to maximum concentrations in the measured data may reoccur in the

[108] The farthest out year for which locomotive emissions were projected was 2030 and those were used in the 2032 case.

[111] 531 F.3d at 910–911 (holding that the EPA must give ''independent significance'' to each prong of CAA section 110(a)(2)(D)(i)(I)).

[112] *See* 63 FR 57375, 57377 (October 27, 1998); 70 FR 25241(January 14, 2005). *See also North Carolina,* 531 F.3d at 913–914 (affirming as reasonable EPA's approach to defining nonattainment in CAIR).

future. The maximum design value gives a reasonable projection of future air quality at the receptor under a scenario in which such conditions do, in fact, reoccur.[113] The projected maximum design value is used to identify upwind emissions that, under those circumstances, could interfere with the downwind area's ability to maintain the NAAQS.

Therefore, applying this methodology in this proposed rule, EPA assessed the magnitude of the maximum projected design values for 2023, 2026, and 2032 at each receptor in relation to the 2015 ozone NAAQS and, where such a value exceeds the NAAQS, the EPA determined that receptor to be a ''maintenance'' receptor for purposes of defining interference with maintenance, consistent with the method used in CSAPR and upheld by the D.C. Circuit in *EME Homer City II.*[114] That is, monitoring sites with a maximum design value that exceeds the NAAQS are projected to have maintenance problems in the future analytic years.[115]

Recognizing that nonattainment receptors are also, by definition, maintenance receptors, the EPA often uses the term ''maintenance-only'' to refer to receptors that are not also nonattainment receptors. Consistent with the concepts for maintenance receptors, as described above, the EPA identifies ''maintenance-only'' receptors as those monitoring sites that have projected average design values above the level of the applicable NAAQS, but that are not currently measuring nonattainment based on the most recent official design values. In addition, those monitoring sites with projected average design values below the NAAQS, but with projected maximum design values above the NAAQS are also identified as ''maintenance only'' receptors, even if they are currently measuring nonattainment based on the most recent official design values.

Consistent with EPA's modeling guidance, the 2016 base year and future year air quality modeling results were used in a relative sense to project design values for 2023, 2026, and 2032. That is, the ratios of future year model predictions to base year model predictions are used to adjust ambient ozone design values[116] up or down depending on the relative (percent) change in model predictions for each location. The modeling guidance recommends using measured ozone concentrations for the 5-year period centered on the base year as the air quality data starting point for future year projections. This average design value is used to dampen the effects of inter-annual variability in meteorology on ozone concentrations and to provide a reasonable projection of future air quality at the receptor under average conditions. In addition, the Agency calculated maximum design values from within the 5-year base period to represent conditions when meteorology is more favorable than average for ozone formation. Because the base year for the air quality modeling used in this proposed rule is 2016, measured data for 2014–2018 (*i.e.,* design values for 2016, 2017, and 2018) were used in order to project average and maximum design values in 2023, 2026, and 2032.

The ozone predictions from the 2016 and future year air quality model simulations were used to project 2016–2018 average and maximum ozone design values to 2023, 2026, and 2032 using an approach similar to the approach in EPA's guidance for attainment demonstration modeling. This guidance recommends using model predictions from the 3 x 3 array of grid cells[117] surrounding the location of the monitoring site to calculate a Relative Response Factor (RRF) for that site.[118] The 2016–2018 base period average and maximum design values were multiplied by the RRF to project each of these design values to each of the three future years. In this manner, the projected design values are grounded in monitored data, and not the absolute model-predicted future year concentrations. Following the approach in the CSAPR Update and the Revised CSAPR Update, the EPA also projected future year design values based on a modified version of the ''3 x 3'' approach for those monitoring sites located in coastal areas. In this alternative approach, EPA eliminated from the RRF calculations the modeling data in those grid cells that are dominated by water (*i.e.,* more than 50 percent of the area in the grid cell is water) and that do not contain a monitoring site (*i.e.,* if a grid cell is more than 50 percent water but contains an air quality monitor, that cell would remain in the calculation). The choice of more than 50 percent of the grid cell area as water as the criteria for identifying overwater grid cells is based on the treatment of land use in the Weather Research and Forecasting model (WRF).[119] Specifically, in the WRF meteorological model those grid cells that are greater than 50% overwater are treated as being 100 percent overwater. In such cases the meteorological conditions in the entire grid cell reflect the vertical mixing and winds over water, even if part of the grid cell also happens to be over land with land-based emissions, as can often be the case for coastal areas. Overlaying land-based emissions with overwater meteorology may be representative of conditions at coastal monitors during times of on-shore flow associated with synoptic conditions or sea-breeze or lake-breeze wind flows. But there may be other times, particularly with off-shore wind flow, when vertical mixing of land-based emissions may be too

[113] The EPA's air quality modeling guidance identifies the use of the highest of the relevant base period design values as a means to evaluate future year attainment under meteorological conditions that are especially conducive to ozone formation. *See* U.S. Environmental Protection Agency, 2018. Modeling Guidance for Demonstrating Attainment of Air Quality Goals for Ozone, $PM_{2.5,}$ and Regional Haze, Research Triangle Park, NC.

[114] *See* 795 F.3d at 136.

[115] The EPA issued a memorandum in October 2018, providing additional information to states developing interstate transport SIP submissions for the 2015 8-hour ozone NAAQS concerning considerations for identifying downwind areas that may have problems maintaining the standard at Step 1 of the 4-step interstate transport framework. *See* Considerations for Identifying Maintenance Receptors for Use in Clean Air Act Section 110(a)(2)(D)(i)(I) Interstate Transport State Implementation Plan Submissions for the 2015 Ozone National Ambient Air Quality Standards, October 19, 2018 (''October 2018 memorandum''), available in Docket No. EPA–HQ–OAR–2021–0663 or at *https://www.epa.gov/airmarkets/memo-and-supplemental-information-regarding-interstate-transport-sips-2015-ozone-naaqs.* The EPA does not propose to adopt the information or suggested analytical approaches in that memorandum in this proposed rule proposing FIPs. Potential alternative approaches would introduce unnecessary and substantial additional analytical burdens that could frustrate timely and efficient implementation of good neighbor obligations. In addition, the information supplied in that memorandum is now outdated due to several additional years of air quality monitoring data and updated modeling results. EPA's current approach to defining ''maintenance'' receptors has been upheld and continues to provide an appropriate approach to addressing the ''interference with maintenance'' prong of the Good Neighbor provision. *See EME Homer City,* 795 F.3d 118, 136–37; *Wisconsin,* 938 F.3d at 325–26.

[116] The ozone design value at a particular monitoring site is the 3-year average of the annual 4th highest daily maximum 8-hour ozone concentration at that site.

[117] As noted above, each model grid cell is 12 x 12 km.

[118] The relative response factor represents the change in ozone at a given site. In order to calculate the RRF, EPA's modeling guidance recommends selecting the 10 highest ozone days in an ozone season at a given monitor in the base year, noting which of the grid cells surrounding the monitor experienced the highest ozone concentrations in the base year, and averaging those ten highest concentrations. The model is then run using the projected year emissions, in this case 2023, with all other model variables held constant. Ozone concentrations from the same ten days, in the same grid cells, are then averaged. The fractional change between the base year (2016 model run) averaged ozone concentrations and the future year (*e.g.,* 2023 model run) averaged ozone concentrations represents the relative response factor.

[119] *https://www.mmm.ucar.edu/weather-research-and-forecasting-model.*

limited due to the presence of overwater meteorology. Thus, for our modeling EPA projected average and maximum design values at individual monitoring sites based on both the ''3 x 3'' approach as well as the alternative approach that eliminates overwater cells in the RRF calculation for near-coastal areas (*i.e.,* ''no water'' approach). The projected 2023, 2026, and 2032 design values using both the ''3 x 3'' and ''no-water'' approaches are provided in the docket for this proposed rule. For this proposed rule, the EPA is relying upon design values based on the ''no water'' approach for identifying nonattainment and maintenance receptors.[120]

Consistent with the truncation and rounding procedures for the 8-hour ozone NAAQS, the projected design values are truncated to integers in units of ppb.[121] Therefore, projected design values that are greater than or equal to 71 ppb are considered to be violating the 2015 ozone NAAQS. For those sites that are projected to be violating the NAAQS based on the average design values in the future analytic years, the Agency examined the measured design values for 2020, which are the most recent official measured design values at the time of this proposal. As noted earlier, the Agency proposes to identify nonattainment receptors in this rulemaking as those sites that are violating the NAAQS based on current measured air quality and also have projected average design values of 71 ppb or greater. Maintenance-only receptors include both (1) those sites with projected average design values above the NAAQS that are currently measuring clean data and (2) those sites with projected average design values below the level of the NAAQS, but with projected maximum design values of 71 ppb or greater. In addition to the maintenance-only receptors, the 2021 ozone nonattainment receptors are also maintenance receptors because the maximum design values for each of these sites is always greater than or equal to the average design value. The monitoring sites that the Agency projects to be nonattainment and maintenance receptors for the ozone NAAQS in the 2023 and 2026 base case are used for assessing the contribution of emissions in upwind states to downwind nonattainment and maintenance of ozone NAAQS as part of this proposal.

Table V.D–1 contains the 2016-centered[122] base period average and maximum 8-hour ozone design values, the 2023 base case average and maximum design values and the 2020 design values for the sites that are projected to be nonattainment receptors in 2023. Table V.D–2 contains this same information for monitoring sites that are projected to be maintenance-only receptors in 2023. The design values for all monitoring sites in the U.S. are provided in the docket for this rule. Additional details on the approach for projecting average and maximum design values are provided in the AQM TSD.

[120] Using design values from the ''3 x 3'' approach, the maintenance-only receptor at site 170317002 in Cook County, IL would become a nonattainment receptor because the average design value with the ''3 x 3'' approach is 71.1 ppb versus 70.1 ppb with the ''no water'' approach. In addition, the monitor at site 170971007 in Lake County, IL which was not projected to be a receptor using the ''no water'' approach would be a maintenance-only receptor with the ''3 x 3'' approach because the maximum design value with the ''no water'' approach was 69.9 ppb versus a maximum design value of 71.2 ppb with the ''3 x 3'' approach. However, including this Lake County, Illinois site as a receptor would not affect which states are covered by this proposed rule.

[121] 40 CFR part 50, Appendix P to Part 50—Interpretation of the Primary and Secondary National Ambient Air Quality Standards for Ozone.

[122] 2016-centered averaged design values represent the average of the design values for 2016, 2017, and 2018. Similarly, the maximum 2016-centered design value is the highest measured design value from these three design value periods.

In total, in the 2023 base case there are a total of 111 receptors nationwide including 85 nonattainment receptors and 26 maintenance-only receptors.[123] Of the 85 nonattainment receptors in 2023, 75 remain nonattainment receptors while 8 are projected to become maintenance-only receptors and 2 are projected to be in attainment in 2026. Of the 26 maintenance-only receptors in 2023, 13 are projected to remain maintenance-only receptors and 13 are projected to be in attainment in 2026. The projected average and maximum design values in 2026 for all receptors are included in the AQM TSD.

E. Pollutant Transport From Upwind States

1. Air Quality Modeling To Quantify Upwind State Contributions

This section documents the procedures the EPA used to quantify the impact of emissions from specific upwind states on ozone design values in 2023 and 2026 for the identified downwind nonattainment and maintenance receptors. The EPA used CAMx photochemical source apportionment modeling to quantify the impact of emissions in specific upwind states on downwind nonattainment and maintenance receptors for 8-hour ozone. CAMx employs enhanced source apportionment techniques that track the formation and transport of ozone from specific emissions sources and calculates the contribution of sources and precursors to ozone for individual receptor locations. The benefit of the photochemical model source apportionment technique is that all modeled ozone at a given receptor location in the modeling domain is tracked back to specific sources of emissions and boundary conditions to fully characterize culpable sources.

The EPA performed nationwide, state-level ozone source apportionment modeling using the CAMx Ozone Source Apportionment Technology/Anthropogenic Precursor Culpability Analysis (OSAT/APCA) technique[124] to quantify the contribution of 2023 and 2026 base case NO_X and VOC emissions from all sources in each state to the corresponding projected ozone design values in 2023 and 2026 at air quality monitoring sites. The CAMx OSAT/APCA model run was performed for the period May 1 through September 30 using the projected future base case emissions and 2016 meteorology for this time period. As described earlier, in the source apportionment modeling the Agency tracked (*i.e.,* tagged) the amount of ozone formed from anthropogenic emissions in each state individually as well as the contributions from other sources (*e.g.,* natural emissions).

In the state-by-state source apportionment model run, the EPA tracked the ozone formed from each of the following tags:

• States—anthropogenic NO_X and VOC emissions from each state tracked individually (emissions from all anthropogenic sectors in a given state were combined);

• Biogenics—biogenic NO_X and VOC emissions domain-wide (*i.e.,* not by state);

• Boundary Concentrations—concentrations transported into the air quality modeling domain;

• Tribes—the emissions from those tribal lands for which the Agency has point source inventory data in the 2016v1 emissions modeling platform (EPA did not model the contributions from individual tribes);

[123] The EPA's modeling also projects that three monitoring sites in the Uintah Basin (*i.e.,* monitor 490472003 in Uintah County, Utah and monitors 490130002 and 490137011 in Duchesne County, Utah) will have average design values above the NAAQS in 2023. However, as described in the AQM TSD, the Uinta Basin nonattainment area was designated as nonattainment for the 2015 ozone NAAQS not because of an ongoing problem with summertime ozone (as is usually the case in other parts of the country), but instead because it violates the ozone NAAQS in winter. The main causes of the Uinta Basin's wintertime ozone are sources located at low elevations within the Basin, the Basin's unique topography, and the influence of the wintertime meteorologic inversions that keep ozone and ozone precursors near the Basin floor and restrict air flow in the Basin. Because of the localized nature of the ozone problem at these sites the EPA has not identified these three monitors as receptors in Step 1 of this proposed rule.

[124] As part of this technique, ozone formed from reactions between biogenic VOC and NO_X with anthropogenic NO_X and VOC are assigned to the anthropogenic emissions.

• Canada and Mexico—anthropogenic emissions from sources in the portions of Canada and Mexico included in the modeling domain (the EPA did not model the contributions from Canada and Mexico separately);

• Fires—combined emissions from wild and prescribed fires domain-wide (*i.e.,* not by state); and

• Offshore—combined emissions from offshore marine vessels and offshore drilling platforms.

The contribution modeling provided contributions to ozone from anthropogenic NO_X and VOC emissions in each state, individually. The contributions to ozone from chemical reactions between biogenic NO_X and VOC emissions were modeled and assigned to the ''biogenic'' category. The contributions from wildfire and prescribed fire NO_X and VOC emissions were modeled and assigned to the ''fires'' category. That is, the contributions from the ''biogenic'' and ''fires'' categories are not assigned to individual states nor are they included in the state contributions.

For the Step 2 analysis, the EPA calculated a contribution metric that considers the average contribution on the 10 highest ozone concentration days (*i.e.,* top 10 days) in 2023. This average contribution metric is intended to provide a reasonable representation of the contribution from individual states to projected future year design values, based on modeled transport patterns and other meteorological conditions generally associated with modeled high ozone concentrations at the receptor. An average contribution metric constructed in this manner is beneficial since the magnitude of the contributions is directly related to the magnitude of the design value at each site.

The analytic steps for calculating the contribution metric for the 2023 analytic year are as follows:

(1) Calculate the 8-hour average contribution from each source tag to each monitoring site for the time period of the 8-hour daily maximum modeled concentrations in 2023;

(2) Average the contributions and average the concentrations for the top 10 modeled ozone concentration days in 2023;

(3) Divide the average contribution by the corresponding average concentration to obtain a Relative Contribution Factor (RCF) for each monitoring site;

(4) Multiply the 2023 average design values by the 2023 RCF at each site to produce the average contribution metric values in 2023.[125]

This same approach was applied to calculate contribution metric values at individual monitoring sites for 2026.[126]

The resulting contributions from each tag to each monitoring site in the U.S. for 2023 and 2026 can be found in the docket for this proposed rule. Additional details on the source apportionment modeling and the procedures for calculating contributions can be found in the AQM TSD.

The largest contribution from each state that is the subject of this rule to 8-hour ozone nonattainment and maintenance receptors in downwind states in 2023 and 2026 are provided in Table V.E.1–1 and Table V.E.1–2, respectively.

TABLE V.E.1–1—LARGEST CONTRIBUTION TO DOWNWIND 8-HOUR OZONE NONATTAINMENT AND MAINTENANCE RECEPTORS IN 2023 (ppb)

Upwind state	Largest contribution to downwind nonattainment receptors	Largest contribution to downwind maintenance-only receptors
Alabama	0.88	0.71
Arizona	0.40	0.21
Arkansas	1.00	1.39
California	34.24	7.44
Colorado	0.07	0.20
Connecticut	0.01	0.21
Delaware	0.53	1.36
District of Columbia	0.04	0.07
Florida	0.16	0.15
Georgia	0.16	0.17

2. Application of Contribution Screening Threshold

The EPA evaluated the magnitude of the contributions from each upwind state to downwind nonattainment and maintenance receptors. In Step 2 of the interstate transport framework, the EPA uses an air quality screening threshold to identify upwind states that contribute to downwind ozone concentrations in amounts sufficient to ''link'' them to these to downwind nonattainment and maintenance receptors. The contributions from each state to each downwind nonattainment or maintenance receptor that were used for the Step 2 evaluation can be found in the AQM TSD.

The EPA proposes to apply an air quality screening threshold of 1 percent of the NAAQS, as it has used since the CSAPR rulemaking, including in the CSAPR Update, the Revised CSAPR Update, and numerous actions evaluating states' transport SIP submittals. EPA continues to observe that the majority of nonattainment and maintenance receptors identified at Step 1 are impacted collectively by contributions of ozone transport from numerous upwind states. Therefore, application of a uniform screening threshold allows EPA to identify upwind states that share a responsibility under the interstate transport provision to eliminate their significant contribution.

The EPA recognizes that in 2018 it issued a memorandum indicating the potential for states to use a higher threshold at Step 2 in the development of their good neighbor SIP submissions where it could be technically justified. The August 2018 memorandum stated that ''it may be reasonable and appropriate'' for states to rely on an alternative 1 ppb threshold at Step 2.[127] (The memorandum also indicated that any higher alternative threshold, such as 2 ppb, would likely not be appropriate.) Here, the EPA proposes to fulfill its role under CAA section 110(c) in promulgating FIPs to directly implement good neighbor requirements, and in this role, the EPA notes that it is authorized to exercise discretion in making policy determinations such as the appropriateness of a particular contribution threshold that would otherwise have been exercised by states. Further, as the EPA has explained in several notices proposing transport SIP disapprovals, *see, e.g.,* 87 FR 9498 and 87 FR 9510 (Feb. 22, 2022), its experience since the issuance of the August 2018 memorandum regarding use of alternative thresholds leads the Agency to now believe it may not be appropriate to continue to attempt to recognize alternative contribution thresholds at Step 2, either in the context of SIPs or FIPs.

EPA's experience since 2018 is that allowing for alternative Step 2 thresholds may be impractical or otherwise inadvisable for a number of additional policy reasons. For a regional air pollutant such as ozone, consistency in requirements and expectations across all states is essential. In the context of a FIP proposal (as much as in the context of SIP actions), the Agency now believes using different thresholds at Step 2 with respect to the 2015 ozone NAAQS raises substantial policy consistency and practical implementation concerns.[128] The availability of different thresholds at Step 2 has the potential to result in inconsistent application of good neighbor obligations. From the perspective of ensuring effective regional implementation of good neighbor obligations, the more important analysis is the evaluation of the emissions reductions needed, if any, to address a state's significant contribution after consideration of a multifactor analysis at Step 3, including a detailed evaluation that considers air quality factors and cost. Where alternative thresholds for purposes of Step 2 may be ''similar'' in terms of capturing the relative amount of upwind contribution (as described in the August 2018 memorandum), nonetheless, use of an alternative threshold would allow certain states to avoid further evaluation of potential emissions controls while other states must proceed to a Step 3 analysis. This can create significant equity and consistency problems among states.

More importantly, in promulgating FIPs to address these obligations on a nationwide scale, national ozone transport policy is not well-served by allowing for less stringent thresholds at Step 2. The EPA recognized in the August 2018 memo that there was some similarity in the amount of total upwind contribution captured (on a nationwide basis) between 1 percent and 1 ppb. However, the EPA notes that while this

[127] August 2018 memo at 4.

[128] We note that Congress has placed on the EPA a general obligation to ensure the requirements of the CAA are implemented consistently across states and regions. *See* CAA section 301(a)(2). Where the management and regulation of interstate pollution levels spanning many states is at stake, consistency in application of CAA requirements is paramount.

may be true in some sense, that is hardly a compelling basis to move to a 1 ppb threshold. Indeed, the 1 ppb threshold has the disadvantage of losing a certain amount of total upwind contribution for further evaluation at Step 3 (*e.g.,* roughly 7 percent of total upwind state contribution was lost according to the modeling underlying the August 2018 memo;[129] in EPA's updated modeling, the amount lost is roughly 5 percent). Considering the core statutory objective of ensuring elimination of *all* significant contribution to nonattainment or interference of the NAAQS in other states and the broad, regional nature of the collective contribution problem with respect to ozone, there does not appear to be a compelling policy imperative in moving to a 1 ppb threshold.

Consistency with past interstate transport actions such as CSAPR, and the CSAPR Update and Revised CSAPR Update rulemakings (which used a Step 2 threshold of 1 percent of the NAAQS for two less stringent ozone NAAQS) is also important. Continuing to use a 1 percent of NAAQS approach ensures that as the NAAQS are revised and made more stringent, an appropriate increase in stringency at Step 2 occurs, so as to ensure an appropriately larger amount of total upwind-state contribution is captured for purposes of fully addressing interstate transport for the more stringent NAAQS. EPA made this point when it originally promulgated CSAPR to address the 1997 ozone NAAQS. The Agency continues to consider this an important consideration for the more stringent 2015 ozone NAAQS. *See* 76 FR 48237–38.

Lastly, the Agency does not find it to be a good use of limited resources to attempt to further justify the use of alternative thresholds for certain states at Step 2 for purposes of the 2015 ozone NAAQS. Therefore, while EPA articulated a potential basis for recognizing the usefulness of alternative Step 2 thresholds (particularly a 1 ppb threshold) in the August 2018 memorandum, EPA's experience and further evaluation since the issuance of that memo has revealed substantial programmatic and policy difficulties in attempting to implement this approach. Depending on comment and further evaluation of this issue, the EPA may determine to rescind the 2018 memorandum in the future.

In light of the considerations above, EPA proposes using a contribution threshold of 0.70 ppb as the quantification of 1 percent of the 2015 ozone NAAQS for purposes of Step 2.

a. States That Contribute Below the Screening Threshold

Based on EPA's modeling, the contributions from each of the following states to nonattainment or maintenance-only receptors in the 2023 analytic year are below the 1% of the NAAQS threshold: Arizona, Colorado, Connecticut, the District of Columbia, Florida, Georgia, Idaho, Iowa, Kansas, Maine, Massachusetts, Montana, Nebraska, New Hampshire, New Mexico, North Carolina, North Dakota, Rhode Island, South Carolina, South Dakota, Vermont, and Washington. The EPA has already approved many of these states' SIP submittals or is in the process of taking action to approve them. Because the contributions from these states to projected downwind air quality problems are below the screening threshold in the current modeling, these states are not within the scope of this proposed rule. Additionally, the EPA has made proposed or final determinations that two states outside the modeling domain for the air quality modeling analyzed in this proposed rulemaking—Hawaii[130] and Alaska[131]—do not significantly contribute to nonattainment or interfere with maintenance of the NAAQS in any other state.

a. States That Contribute at or Above the Screening Threshold

Based on the maximum downwind contributions in Table V.E.1–1, the Step 2 analysis identifies that the following 22 states contribute at or above the 0.70 ppb threshold to downwind nonattainment receptors in 2023: Alabama, Arkansas, California, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oregon, Pennsylvania, Texas, Utah, Virginia, West Virginia, and Wyoming. Based on the maximum downwind contributions in Table V.E.1–1, the following 23 states contribute at or above the 0.70 ppb threshold to downwind maintenance-only receptors in 2023: Alabama, Arkansas, California, Delaware, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, New Jersey, New York, Ohio, Oklahoma, Oregon, Tennessee, Texas, Virginia, West Virginia, and Wisconsin. The levels of contribution between each of these linked upwind states and downwind nonattainment receptors and maintenance-only receptors are provided in the AQM TSD.

Among the linked states are several western states—California, Nevada, Oregon, Utah, and Wyoming. While the EPA has not previously included action on linked western states in its prior CSAPR rulemakings, the EPA has consistently applied the 4-step framework in evaluating good neighbor obligations from these states. On a case-by-case basis, the EPA has found in some instances with respect to the 2008 ozone NAAQS that a unique consideration has warranted approval of a linked western state's good neighbor SIP submittal without concluding that additional emissions reductions are required at Step 3 of the framework.[132] The EPA has also explained in prior actions that its air quality modeling is reliable for assessing downwind air quality problems and ozone transport contributions from upwind states throughout the nationwide modeling domain.[133]

In EPA's current analysis, the EPA finds that for one linked state—Oregon—the same considerations that led it to approve another state's SIP submission, Arizona's, for the 2008 ozone NAAQS apply to Oregon's circumstances for the 2015 ozone NAAQS. As explained in the following section, the EPA therefore proposes to affirm its prior approval of Oregon's good neighbor SIP submission for the 2015 ozone NAAQS. For the remaining western states included in this proposed rule, EPA's modeling supports a conclusion that these states are linked above the contribution threshold to identified ozone transport receptors in other states, and therefore, consistent with the treatment of all other states within the modeling domain, the EPA proposes to proceed to evaluate these states for a determination of ''significant contribution'' at Step 3.

In conclusion, as described above, states with contributions that equal or exceed 1 percent of the NAAQS to either nonattainment or maintenance receptors are identified as ''linked'' at Step 2 of the good neighbor framework and warrant further analysis for significant contribution to nonattainment or interference with

[129] *See* August 2018 memo, at 4.

[130] The EPA proposed to approve Hawaii's 2015 ozone transport SIP on September 28, 2021. *See* 86 FR 53571.

[131] The EPA approved Alaska's 2015 ozone transport SIP on December 18, 2019. *See* 84 FR 69331.

[132] *See* interstate transport approval actions under the 2008 ozone NAAQS for Arizona, California, and Wyoming at 81 FR 36179 (June 6, 2016), 83 FR 65093 (December 19, 2018), and 84 FR 14270 (April 10, 2019), respectively.

[133] *See* 81 FR 71991 (October 19, 2016), 82 FR 9155 (February 3, 2017).

maintenance under Step 3. The EPA proposes that the following 27 States are linked at Step 2 in 2023: Alabama, Arkansas, California, Delaware, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Oregon, Pennsylvania, Tennessee, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming. In addition, the EPA proposes that the following 24 States are linked at Step 2 in 2026: Arkansas, California, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Oregon, Pennsylvania, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming. Three states, Alabama, Delaware, and Tennessee, that were linked in 2023 are not linked in 2026 because the receptor(s) to which each state was linked in 2023 are projected to attain by 2026.

F. Treatment of Certain Receptors in California and Implications for Oregon's Good Neighbor Obligations for the 2015 Ozone NAAQS

The EPA previously approved Oregon's September 25, 2018 transport SIP submittal for the 2015 ozone NAAQS on May 17, 2019 (84 FR 22376), because in an earlier round of modeling Oregon was not projected to contribute above 1 percent of the NAAQS to any downwind receptors. In EPA's updated modeling, Oregon is linked above the 1 percent of NAAQS threshold to several monitoring sites in California that would generally meet EPA's definition of nonattainment or maintenance ''receptors'' at Step 1.[134] However, EPA's analysis of the nature of the air quality problem at these monitoring sites leads EPA to propose a determination that these monitoring sites should not be treated as receptors for purposes of determining interstate transport obligations of upwind states under CAA section 110(a)(2)(D)(i)(I). EPA reaches this conclusion at Step 1 of its four-step framework.

The EPA previously made a similar assessment of the nature of certain other monitoring sites in California in approving Arizona's 2008 ozone NAAQS transport SIP submittal.[135] There, the EPA noted that a ''factor [. . .] relevant to determining the nature of a projected receptor's interstate transport problem is the magnitude of ozone attributable to transport from all upwind states collectively contributing to the air quality problem.'' [136] The EPA observed that only one upwind state (Arizona) was linked above 1 percent of the 2008 ozone NAAQS to the two relevant monitoring sites in California, and the cumulative ozone contribution from all upwind states to those sites was 2.5 percent and 4.4 percent of the total ozone, respectively. The EPA determined the size of those cumulative upwind contributions was ''negligible, particularly when compared to the relatively large contributions from upwind states in the East or in certain other areas of the West.'' [137] In that action, the EPA concluded the two California sites to which Arizona was linked should not be treated as receptors for the purposes of determining Good Neighbor obligations for the 2008 ozone NAAQS.[138]

The EPA proposes to make a similar finding for the monitoring sites in California otherwise projected in its current modeling to be ''receptors'' for the 2015 ozone NAAQS and to which Oregon is linked. The highest percent of the total cumulative upwind ozone contribution to any of these sites is 2.8 percent.[139] This is lower than the largest transport contribution relative to total ozone at the California sites identified in EPA's approval of Arizona's 2008 ozone transport SIP (4.4 percent).[140] Further, as was the case for the sites in California analyzed in EPA's Arizona action, the identified sites in California each have only one upwind state contributing above 1 percent of the NAAQS to them (Oregon). These monitoring sites in California are overwhelmingly impacted by in-state emissions to a degree not comparable with any other identified nonattainment or maintenance-only receptors in the country.

The EPA proposes to find that these monitoring sites should not be considered receptors for the purpose of assessing 2015 ozone NAAQS interstate transport obligations. The EPA is not proposing a different contribution threshold at Step 2 for Western states or receptors, nor does the EPA reach its conclusion based on any evaluation at Step 3 of emissions reduction opportunities in Oregon.

As a consequence of this proposed finding, the EPA continues to find that ozone-precursor emissions from Oregon do not significantly contribute to nonattainment or interfere with maintenance of the NAAQS in any downwind state, because the total collective upwind state ozone contribution to the California monitoring sites is extremely low compared to the air quality problems typically addressed under the good neighbor provision. Therefore, the EPA is not proposing any change in this action to its prior approval of Oregon's SIP. The EPA is not proposing any new FIP requirements and is not proposing to require reductions from new or existing EGU or non-EGU sources in Oregon in this action. If, however, EPA were not to finalize this proposed approach, then EPA anticipates that it would apply the same control strategies in Oregon as applied in all other linked upwind states, as discussed in Sections VI and VII of this proposed rule. EPA requests public comment on its approach to characterizing the nature of the interstate transport problem at the California monitoring sites at issue and the consequent approach to assessing Oregon's good neighbor obligations.

VI. Quantifying Upwind-State NO_X Emissions Reduction Potential To Reduce Interstate Ozone Transport for the 2015 Ozone NAAQS

A. The Multi-Factor Test for Determining Significant Contribution

This section describes EPA's methodology at Step 3 of the 4-step framework for identifying upwind emissions that constitute ''significant'' contribution for the states subject to this proposed rule and focuses on the 26 states with FIP requirements identified in the sections above. Following the existing framework as applied in all of the prior CSAPR rulemakings, EPA's assessment of linked upwind state emissions is based primarily on analysis of several alternative levels of NO_X emissions control stringency applied uniformly across all of the linked states. The analysis includes assessment of non-EGU stationary sources in addition to EGU sources in the linked upwind states.

The EPA applies a multi-factor test—the same multi-factor test that was used in CSAPR, the CSAPR Update, and the Revised CSAPR Update [141]—to evaluate increasing levels of uniform NO_X control stringency. The multi-factor test, which is central to EPA's Step 3

[134] Monitors are listed in the AQM TSD included in the docket for this rulemaking. While EPA is providing information about cumulative upwind contribution to the California monitors, the Agency does not consider these monitors as ozone transport receptors in this proposal.

[135] 81 FR 15200 (March 22, 2016) (proposal); 81 FR 31513 (May 19, 2016) (final rule).

[136] 81 FR at 15203.

quantification of significant contribution, considers cost, available emissions reductions, downwind air quality impacts, and other factors to determine the appropriate level of uniform NO_X control stringency that would eliminate significant contribution to downwind nonattainment or maintenance receptors. The selection of a uniform level of NO_X emissions control stringency across all of the linked states, reflected as a representative cost per ton of emissions reduction (or a weighted average cost per ton in the case of EPA's non-EGU and EGU analysis for 2026 mitigation measures), also serves to apportion the reduction responsibility among collectively contributing upwind states. This approach to quantifying upwind state emission-reduction obligations using uniform cost was reviewed by the Supreme Court in *EME Homer City Generation,* which held that using such an approach to apportion emissions reduction responsibilities among upwind states that are collectively responsible for downwind air quality impacts ''is an efficient and equitable solution to the allocation problem the Good Neighbor Provision requires the Agency to address.'' 572 U.S. at 519.

There are four stages in developing the multi-factor test: (1) Identify levels of uniform NO_X control stringency; (2) evaluate potential NO_X emissions reductions associated with each identified level of uniform control stringency; (3) assess air quality improvements at downwind receptors for each level of uniform control stringency; and (4) select a level of control stringency considering the identified cost, available NO_X emissions reductions, and downwind air quality impacts, while also ensuring that emissions reductions do not unnecessarily over-control relative to the contribution threshold or downwind air quality.

As mentioned in Section IV.A.2 of this proposed rule, commenters on previous ozone transport rules have suggested that the EPA should regulate VOCs as an ozone precursor. For this proposed rule, the EPA examined the results of the contribution modeling performed for this rule to identify the portion of the ozone contribution attributable to anthropogenic NO_X emissions versus VOC emissions from each linked upwind state to each downwind receptor. Of the total upwind-downwind linkages in 2023, the contributions from NO_X emissions comprise 80 percent or more of the total anthropogenic contribution at the vast majority of linkages (136 out of 140 total). Across all receptors, the contribution from NO_X emissions ranges from 77 percent to 99 percent of the total anthropogenic contribution. This review of the portion of the ozone contribution attributable to anthropogenic NO_X emissions versus VOC emissions from each linked upwind state leads the Agency to conclude that the vast majority of the downwind air quality areas addressed by the proposed rule under are primarily NO_X-limited, rather than VOC-limited. Therefore, the EPA is proposing to determine that the regulation of VOCs as an ozone precursor is not necessary to eliminate significant contribution of ozone transport to downwind areas in this proposed rule. The remainder of this section focuses on EPA's strategy for reducing regional-scale transport of ozone by targeting NO_X emissions from stationary sources to achieve the most effective reductions of ozone transport over the geography of the affected downwind areas.

For both EGUs and non-EGUs, Section VI.B of this proposed rule describes the available NO_X emissions controls that the EPA evaluated for this proposed rule and their representative cost levels (in 2016$). Section VI.C of this proposed rule discusses EPA's application of that information to assess emissions reduction potential of the identified control stringencies. Finally, Section VI.D of this proposed rule describes EPA's assessment of associated air quality impacts and EPA's subsequent identification of appropriate control stringencies considering the key relevant factors (cost, available emissions reductions, and downwind air quality impacts).

This multi-factor approach is consistent with EPA's approach in prior transport actions, such as CSAPR. In addition, as was evaluated in the CSAPR Update and Revised CSAPR Update, the EPA evaluated possible over-control by examining whether an upwind state is linked solely to downwind air quality problems that could have been resolved at a lesser threshold of control stringency and whether an upwind state could reduce its emissions below the 1 percent air quality contribution threshold at a lesser threshold of control stringency. This analysis is described in Section VI.D of this proposed rule.

Finally, while the EPA has evaluated potential emissions reductions from non-EGU sources in prior rules, this is the first action for which the EPA is proposing non-EGU emissions reductions within the context of its 4-step interstate transport framework. The EPA applies its multi-factor test to non-EGUs and independently evaluates non-EGU industries in a consistent but parallel track to its Step 3 assessment for EGUs. This is consistent with the parallel assessment approach taken for EGUs and non-EGUs in the Revised CSAPR Update. Following the conclusions of the EGU and non-EGU multi-factor tests, the identified reductions for EGUs and non-EGUs are combined and collectively analyzed to assess their effects on downwind air quality and whether the rule achieves a full remedy to ''significant contribution'' while avoiding over-control.

In order to ensure that this rule implements a full remedy for the elimination of significant contribution from upwind states, the EPA has reviewed available information on all major industrial source sectors in the upwind states. This analysis leads the EPA to propose that both EGUs and certain large sources in several specific industrial categories should be evaluated for emissions control opportunities. As discussed in the sections that follow, the EPA proposes that for both EGUs and the selected non-EGU source categories, there are impactful emissions reduction opportunities available at reasonable cost-effectiveness thresholds. As in the Revised CSAPR Update, the EPA examines EGUs and non-EGUs in this section on consistent but distinct, parallel tracks due to differences stemming from the unique characteristics of the power sector compared to other industrial source categories. Since the NO_X SIP Call, EGUs have consistently been regulated under ozone transport rules. These units operate in a coordinated manner across a highly interconnected electrical grid. Their configuration and emissions control strategies are relatively homogenous, and their emissions levels and emissions control opportunities are generally very well understood due to longstanding monitoring and data-reporting requirements. Non-EGU sources, by contrast, are relatively heterogeneous, even within a single industrial category, and have far greater variation in existing emissions control requirements, emissions levels, and technologies to reduce emissions. In general, despite these differences, the information available for this proposal indicates that both EGUs and certain non-EGU categories have available cost-effective NO_X emissions reduction opportunities at relatively commensurate cost per ton levels, and these emissions reductions will make a meaningful improvement in air quality at the downwind receptors. Section VI.B.2 of this proposed rule describes EPA's process for selecting specific Tier I and Tier II non-EGU source categories included in this proposed rulemaking.

The EPA notes that its Step 3 analysis does not assess emissions reduction opportunities from mobile sources. The EPA continues to believe that title II of the CAA provides the primary authority and process for reducing ozone-precursor pollutants from mobile sources. EPA's federal mobile source programs have delivered and are projected to continue to deliver substantial nationwide reductions in both VOCs and NO_X emissions; these reductions are factored into the Agency's assessment of air quality and contributions at Steps 1 and 2. Further, states are generally preempted from regulating new vehicles and engines with certain exceptions, and therefore a question exists regarding EPA's authority to address such emissions when regulating in place of the states under CAA section 110(c). *See generally* CAA sections 209, 177. *See also* 86 FR 23099. As noted earlier, the EPA accounted for mobile source emissions reductions resulting from other federally enforceable regulatory programs in the development of emissions inventories used to support analysis for this proposed rulemaking, and the EPA does not evaluate any mobile source control measures in its Step 3 evaluation in this proposal.[142] For further discussion of EPA's existing and ongoing mobile source measures, *see* Section VI.B.4 of this proposed rule.

B. Identifying Control Stringency Levels

1. EGU NO_X Mitigation Strategies

In identifying levels of uniform control stringency for EGUs, the EPA assessed the same NO_X emissions controls that the Agency analyzed in the CSAPR Update and the Revised CSAPR Update, all of which are considered to be widely available in this sector: (1) Fully operating existing SCR, including both optimizing NO_X removal by existing operational SCRs and turning on and optimizing existing idled SCRs; (2) installing state-of-the-art NO_X combustion controls; (3) fully operating existing SNCRs, including both optimizing NO_X removal by existing operational SNCRs and turning on and optimizing existing idled SNCRs; (4) installing new SNCRs; (5) installing new SCRs; and (6) generation shifting (*i.e.,* emission reductions anticipated to occur from generation shifting from higher to lower emitting units at each of these stringency levels). For the reasons explained in the EGU NO_X Mitigation Strategies Proposed Rule TSD included in the docket for this proposed rule, the EPA determined that for the regional, multi-state scale of this rulemaking, only EGU NO_X emissions controls 1, 3, and 6 are possible for the 2023 ozone season (fully operating existing SCRs and SNCRs, and associated generation shifting). The EPA finds that it is not possible to install state-of-the-art NO_X combustion controls by the 2023 ozone season on a regional scale for Group 3 states not covered under the Revised CSAPR Rule. The EPA also determined that state-of-the-art NO_X combustion controls at EGUs are available by the beginning of the 2024 ozone season. All cost values discussed below for EGUs are in 2016 dollars.

a. Optimizing Existing SCRs

Optimizing (*i.e.,* turning on idled or improving operation of partially operating) existing SCRs can substantially reduce EGU NO_X emissions quickly, using investments that have already been made in pollution control technologies. With the promulgation of the CSAPR Update and the Revised CSAPR Update, most operators in the covered states improved their SCR performance and have continued to maintain that level of improved operation. However, this optimized SCR performance was not universal and not always sustained. Between 2017 and 2020, as the CSAPR Update ozone-season NO_X allowance price declined, NO_X emissions rates at some SCR-controlled EGUs increased. For example, power sector data from 2019 revealed that, in some cases, operating units had SCR controls that had been idled or were operating partially, and therefore suggested that there remained emissions reduction potential through optimization.[143] The EPA determined that optimizing all of these remaining SCRs in the 12 linked states for the Revised CSAPR Update was a readily available approach for EGUs to reduce NO_X emissions. This emissions reduction measure is currently available at EGUs across the broader geography affected in this proposed rulemaking (including in states not previously affected by the Revised CSAPR Update). The EPA thus proposes that SCR optimization, of both idled and partially operating controls, is a viable mitigation strategy for the 2023 ozone season.

The EPA estimates a representative marginal cost of optimizing SCR controls to be approximately $1,600 per ton, consistent with its estimation in the Revised CSAPR Update for this technology. EPA's EGU NO_X Mitigation Strategies Proposed Rule TSD for this rule describes a range of cost estimates for this technology noting that the costs are frequently lower than—and for the majority of EGUs, significantly lower than—this representative marginal cost. While the costs of optimizing existing, operational SCRs include only variable costs, the cost of optimizing SCR units that are currently idled considers both variable and fixed costs of returning the control into service. Variable and fixed costs include labor, maintenance and repair, parasitic load, and ammonia or urea for use as a NO_X reduction reagent in SCR systems. Depending on a unit's control operating status, the representative cost at the 90th percentile unit (among the relevant fleet of coal units with SCR covered in this rulemaking) ranges between $900 and $1,700 per ton. The EPA performed an in-depth cost assessment for all coal-fired units with SCRs and found that for the subset of SCRs that are already partially operating, the cost of optimizing is often much lower than $1,600 per ton and is often under $900 per ton. The EPA anticipates the vast majority of realized cost for compliance with this strategy to be better reflected by the $900 per ton end of that range (reflecting the 90th percentile of EGUs optimizing SCRs that are already partially operating) because this circumstance is considerably more common than EGUs that have ceased operating their SCR. EPA's analysis of this emissions control is informed by the latest engineering modeling equations used in EPA's IPM platform. These cost and performance equations were recently updated in the summer of 2021. The description and development of the equations are documented in EGU NO_X Mitigation Strategies Proposed Rule TSD and accompanying documents.[144] They are also

[142] The EPA recognizes that mechanisms exist under title I of the CAA that allow for the regulation of the use and operation of mobile sources to reduce ozone-precursor emissions. These include motor vehicle inspection and maintenance (I/M) programs, gasoline vapor recovery, clean-fuel vehicle programs, transportation control programs, and vehicle miles traveled programs. *See, e.g.,* CAA sections 182(b)(3), 182(b)(4), 182(c)(3), 182(c)(4), 182(c)(5), 182(d)(1), 182(e)(3), and 182(e)(4). The EPA views these programs as most effective and appropriate in the context of the planning requirements applicable to designated nonattainment areas.

[143] *See* ''Ozone Season Data 2018 vs. 2019'' and ''Coal-fired Characteristics and Controls'' at *https://www.epa.gov/airmarkets/power-plant-data-highlights#OzoneSeason.*

[144] The CSAPR Update estimated $1,400 per ton as a representative cost of turning on idled SCR controls. EPA used the same costing methodology

Continued

implemented in an interactive spreadsheet tool called the Retrofit Cost Analyzer and applied to all units in the fleet. These materials are available in the docket for this proposal.

The EPA is using the same methodology to identify SCR performance as it did in the Revised CSAPR Update. To estimate EGU NO_X reduction potential from optimizing, the EPA considers the difference between the non-optimized NO_X emissions rates and an achievable operating and optimized SCR NO_X emissions rate. To determine this rate, EPA evaluated nationwide coal-fired EGU NO_X ozone season emissions data from 2009 through 2019 and calculated an average NO_X ozone season emissions rate across the fleet of coal-fired EGUs with SCR for each of these eleven years. The EPA found it prudent to not consider the lowest or second-lowest ozone season NO_X emissions rates, which may reflect SCR systems that have all new components (*e.g.,* new layers of catalyst). Data from these systems are potentially not representative of ongoing achievable NO_X emissions rates considering broken-in components and routine maintenance schedules. To identify the potential reductions from SCR optimization in this proposed rule, the EPA followed the same methodology as the Revised CSAPR Update. Considering the emissions data over the full time period from 2009–2019 data results in a third-best rate of 0.079 pounds NO_X per million British thermal units (lb/mmBtu).[145] Therefore, consistent with the Revised CSAPR Update, where EPA identified 0.08 lb/mmBtu as a reasonable level of performance for units with optimized SCR, the EPA proposes a rate of 0.08 lb/mmBtu as the optimized rate for this rule. The EPA notes that half of the SCR-controlled EGUs achieved a NO_X emissions rate of 0.064 lbs/mmBtu or less over their third-best entire ozone season. Moreover, for the SCR-controlled coal units that the EPA identified as having a 2021 emissions rate greater than 0.08 lb/mmBtu, the EPA verified that in prior years, the majority (more than 90 percent) of these same units had demonstrated and achieved a NO_X emissions rate of 0.08 lb/mmBtu or less on a seasonal or monthly basis. This further supports EPA's determination that 0.08 lb/mmBtu reflects a reasonable emissions rate for representing SCR optimization at coal steam units in identifying uniform control stringency. This emissions rate assumption of 0.08 lb/mmBtu reflects what those units would achieve on average when optimized, recognizing that individual units may achieve lower or higher rates based on unit-specific configuration and dispatch patterns. Units historically performing at, or better, than this rate of 0.08 lb/mmBtu are assumed to continue to operate at that prior performance level.

Given the magnitude and duration of the air quality problems addressed by this rulemaking, the EPA also applied the same methodology to identify a reasonable level of performance for optimizing existing SCRs at oil- and gas-fired steam units and simple cycle units (for which EPA determined that a 0.03 lb/mmBtu emissions rate reflected SCR optimization) as well as at combined-cycle units (for which the EPA determined that a 0.012 lb/mmBtu emissions rate reflected SCR optimization).

The EPA evaluated the feasibility of optimizing idled SCRs for the 2023 ozone season. Based on industry past practice, the EPA determined that idled controls can be restored to operation quickly (*i.e.,* in less than 2 months). This timeframe is informed by many electric utilities' previous long-standing practice of utilizing SCRs to reduce EGU NO_X emissions during the ozone season while putting the systems into protective lay-up during the non-ozone season months. For example, this was the long-standing practice of many EGUs that used SCR systems for compliance with the NO_X Budget Trading Program. It was quite typical for SCRs to be turned off following the September 30 end of the ozone season control period. These controls would then be put into protective lay-up for several months of non-use before being returned to operation by May 1 of the following ozone season.[146] Therefore, the EPA believes that optimization of existing SCRs is possible for the portion of the 2023 ozone season covered under this proposed rule.

The vast majority of SCR-controlled units (nationwide and in the 25 linked states for which EPA is issuing a FIP for EGUs) are already partially operating these controls during the ozone season based on reported 2021 emissions rates. Existing SCRs operating at partial capacity still provide functioning, maintained systems that may only require an increased chemical reagent feed rate (*i.e.,* ammonia or urea) up to their design potential and catalyst maintenance for mitigating NO_X emissions; such units may require increased frequency or quantity of deliveries, which can be accomplished within a few weeks. In many cases, EGUs with SCR have historically achieved more efficient NO_X removal rates than their current performance and can therefore simply revert to earlier operation and maintenance plans that achieved demonstrably better SCR performance.

In the 12 states subject to this control stringency in the Revised CSAPR Update, the EPA observed significant immediate-term improvements in SCR performance in the first ozone season following finalization of that rule, as evidenced in particular by the sharp drop in emissions rate at Miami Fort unit 7 (*see* EGU NO_X Mitigation Strategies Proposed Rule TSD). Such empirical data further illustrates the viability of this mitigation strategy for the 2023 control period in response to this rule.

b. Installing State-of-the-Art NO_X Combustion Controls

The EPA estimates that the representative cost of installing state-of-the-art combustion controls is comparable to, if not notably less than, the estimated cost of optimizing existing SCR (represented by $1,600 per ton). State-of-the-art combustion controls such as low-NO_X burners (LNB) and over-fire air (OFA) can be installed or updated quickly and can substantially reduce EGU NO_X emissions. Nationwide, approximately 99 percent of coal-fired EGU capacity greater than 25 MW is equipped with some form of combustion control; however, the control configuration or corresponding emissions rates at a small portion of those units (including units in those states covered in this action) indicate they do not currently have state-of-the-

while updating for input cost increases (*e.g.,* urea reagent) to arrive at $1,600 per ton in the final Revised CSAPR Update (while also updating from 2011 dollars to 2016 dollars).

[145] The EPA notes that updating the inventory of units to reflect recent retirements and most recent year data (*e.g.,* 2009–2021) would provide a lower value of 0.071 lb/mmBtu. This value is lower than the 0.08 pounds per million British thermal units (lb/mmBtu) assessed in the Revised CSAPR Update as it reflects 2020 data and also excludes the SCR performance of since retired coal units with SCRs. However, 2020 was an outlier year (related to pandemic impacts on the electric grid). Additionally, a unit's retirement does not obviate the usefulness of its data for assessing technology performance. Consequently, EPA is proposing the same value of 0.08 lb/mmBtu identified at the time of the final Revised CSAPR Update Rule.

[146] In the 22-state CSAPR Update region, 2005 EGU NO_X emissions data suggest that 125 EGUs operated SCR systems in the summer ozone season while idling these controls for the remaining 7 non-ozone season months of the year. Units with SCR were identified as those with 2005 ozone season average NO_X rates that were less than 0.12 lbs/mmBtu and 2005 average non-ozone season NO_X emissions rates that exceeded 0.12 lbs/mmBtu and where the average non-ozone season NO_X rate was more than double the ozone season rate.

art combustion control technology. As described in the Revised CSAPR Update, the Agency updated its NO_X emissions rates for upgrading existing combustion controls to state-of-the-art combustion control. The EPA is maintaining its determination that NO_X emissions rates of 0.146 to 0.199 lbs/mmBtu can be achieved on average depending on the unit's boiler configuration,[147] and, once installed, reduce NO_X emissions at all times of EGU operation.

These assumptions are consistent with the Revised CSAPR Update and they are further discussed in the EGU NO_X Mitigation Strategies Proposed Rule TSD. In particular, the EPA proposes to apply the 0.199 lb/mmBtu emissions rate assumption for all unit types, consistent with its determination in the Revised CSAPR Update. The average emissions rate assumption derived from EPA's analysis would be 0.199 lb/mmBtu for combustion controls on dry bottom wall fired units and 0.146 lb/mmBtu for tangentially fired units. However, stakeholders have provided detailed analysis of how other unit considerations, such as coal rank, can result in large deviations from what has been historically demonstrated with this combustion control technology. Based on this and EPA's review of historical performance data for tangentially-fired units by coal rank with state-of-the-art combustion controls, the EPA determined in the final Revised CSAPR Update that it was appropriate to use the 0.199 lb/mmBtu rate for both tangentially and wall-fired units when estimating reduction potential for units with combustion control upgrade potential.

The EPA proposes to continue that approach in this action. Many of the likely impacted units burn bituminous coal, and the 0.146 lb/mmBtu nationwide average for tangentially-fired (inclusive of subbituminous units) appears to be below the demonstrated emissions rate of state-of-the-art combustion controls for bituminous coal units of this boiler type. Therefore, EPA's assumption of 0.199 lb/mmBtu for combustion controls is robust to current and future coal choice at a unit.

In promulgating CSAPR, the EPA examined the feasibility of installing combustion controls, and found that industry had demonstrated ability to install state-of-the-art LNB controls on a large unit (800 MW) in under six months when including the pre-installation phases (design, order placement, fabrication, and delivery).[148] In prior rules, the EPA has documented its own assessment of combustion control timing installation as well as evaluated comments it received regarding installation of combustion controls from the Institute of Clean Air Companies.[149] Those comments provided information on the equipment and typical installation time frame for new combustion controls, accounting for all steps. Commenters noted that it generally takes between 6–8 months on a typical boiler—covering the time through bid evaluation through start-up of the technology. The deployment schedule is repeated here as:

- 4–8 weeks—bid evaluation and negotiation
- 4–6 weeks—engineering and completion of engineering drawings
- 2 weeks—drawing review and approval from user
- 10–12 weeks—fabrication of equipment and shipping to end user site
- 2–3 weeks—installation at end user site
- 1 week—commissioning and start-up of technology

Given the above timeframe of approximately 6 to 8 months to complete combustion control installation in the region, the EPA is proposing to determine that installation of state-of-the-art combustion controls is a readily available approach for EGUs to reduce NO_X emissions by the start of the 2024 ozone season. More details on these analyses can be found in the EGU NO_X Mitigation Strategies Proposed Rule TSD.

The cost of installing state-of-the-art combustion controls per ton of NO_X reduced is dependent on the combustion control type and unit type. The EPA estimates the cost per ton of state-of-the-art combustion controls to be $400 per ton to $1,200 per ton of NO_X removed using a representative capacity factor of 85 percent. This cost fits well within EPA's representative cost threshold observed for SCR optimization and combustion controls (of $1,600 per ton) which would accommodate combustion control upgrade even under scenarios where a lower capacity factor is assumed. *See* the EGU NO_X Mitigation Strategies Proposed Rule TSD for additional details.

c. Optimizing Already Operating SNCRs or Turning on Idled Existing SNCRs

Optimizing already operating SNCRs or turning on idled existing SNCRs can also reduce EGU NO_X emissions quickly, using investments in pollution control technologies that have already been made. Compared to no post-combustion controls on a unit, SNCRs can achieve a 25 percent reduction on average in EGU NO_X emissions (with sufficient reagent). They are less capital intensive but less efficient at NO_X removal than SCRs. These controls are in use to some degree across the U.S. power sector. In the 25 linked states identified in this proposed rule with identified EGU reductions in their proposed FIP, approximately 11 percent of coal-fired EGU capacity is equipped with SNCR.[150] Recent power sector data suggest that, in some cases, SNCR controls have been operating less in 2021 relative to performance in prior years.

The EPA determined that optimizing already operating SNCRs or turning on idled SNCRs is an available approach for EGUs to reduce NO_X emissions, has similar implementation timing to restarting idled SCR controls (less than 2 months for a given unit), and therefore could be implemented in time for the 2023 ozone season. The EPA is proposing implementation of this emissions control technology beginning in the 2023 ozone season.

Using an updated data assessment using the Retrofit Cost Analyzer described in the EGU NO_X Mitigation Strategies Proposed TSD, the EPA estimates a representative cost of optimizing SNCR ranging from approximately $1,800 per ton (for partially operating SNCRs) to $3,900 per ton (for idled SNCRs). For existing SNCRs that have been idled, unit operators may need to restart payment of some fixed and variable operating costs including labor, maintenance and repair, parasitic load, and ammonia or urea. The EPA determined that the majority of units with existing SNCR optimization potential were already partially operating their controls. Therefore, the EPA proposes a representative cost of $1,800 per ton for SNCR optimization as this value best reflects the circumstances of the majority of the affected EGUs with SNCR.

[147] Details of EPA's assessment of state-of-the-art NO_X combustion controls are provided in the EGU NO_X Mitigation Strategies Proposed Rule TSD.

[148] The EPA finds that, generally, the installation phase of state-of-the-art combustion control upgrades—on a single-unit basis—can be as little as 4 weeks to install with a scheduled outage (not including the pre-installation phases such as permitting, design, order, fabrication, and delivery) and as little as 6 months considering all implementation phases.

d. Installing New SNCRs

Like existing SNCRs, new SNCR retrofit is also available to power plants and can achieve a 25% NO_X reduction on average. The EPA evaluated potential emissions reductions and associated costs from retrofitting EGUs with new SNCR post-combustion controls at steam units lacking such controls. New SNCR technology provides owners with a relatively less capital-intensive option for reducing NO_X emissions compared to new SCR technology, albeit at the expense of higher operating costs on a per-ton basis and less total emissions reduction potential. SNCR is more widely observed on relatively smaller coal units given its low capital/variable cost ratio. The average capacity of a coal unit with SNCR is half the size of the average capacity of coal unit with SCR.[151] Given these observations, the EPA identifies this technology as an emissions reduction measure for coal units less than 100 MW lacking post-combustion NO_X control technology. As described in the EGU NO_X Mitigation Strategies Proposed Rule TSD, the EPA estimated that $6,700 per ton reflects a representative SNCR retrofit cost level for a majority of these units.

SNCR installations generally have shorter project installation timeframes relative to other post-combustion controls. The time for engineering review, contract award, fabrication, delivery, and hookup is as little as 16 months including pre-contract award steps for an individual power plant installing controls on more than one boiler. This timeframe would mean the control would be available for the start of the 2024 or 2025 ozone season (*i.e.,* calculating 16 months from when this proposal is finalized). However, SNCR retrofits have less pollution reduction potential than alternative post-combustion controls such as SCRs. The EPA is not identifying SNCR technology as a strategy for larger steam units due to this lower removal efficiency and the empirical evidence of existing sources preferring the more efficient SCRs. Even for those smaller units less than 100 MWs identified as potential candidates for this technology, the EPA does not want to preclude those units from pursuing more advanced pollution controls. Therefore, the EPA also considers the point in time when all types of post-combustion control installation could be achieved—*i.e.,* by the 2026 ozone season. SNCR installation share similar implementation steps with and also need to account for the same regional factors as SCR installations.[152] Therefore, while the EPA is determining that at least 16 months would be needed to complete all necessary steps of SNCR development and installation at the EGUs not currently equipped with SNCRs in the 25 states linked to downwind receptors in this proposed rule, the EPA notes that the Agency evaluated SNCR as a post-combustion control technology collectively with SCR and estimated installation timing considerations of 36 months. EPA believes its proposed collective timing considerations for post-combustion control retrofit (SNCR and SCR) are practicable given that the preferable capital-intensive investment retrofit decision would be highly unit-specific and subject to a unit's compliance strategy choices with respect to multiple regulatory requirements.

Nonetheless, the EPA is requesting comment on whether post-combustion control timing assumptions (SCR and SNCR) should be decoupled, which would result in the EPA using the 16-month time frame specific to SNCR installation to estimate the first year in which these reductions are available. The EPA is only identifying this technology for units less than 100 MW (a size at which units rarely implement SCR retrofit technology). In effect, decoupling these timing assumptions would move the reductions associated with this control stringency from beginning in the 2026 ozone season to beginning in the 2024 or 2025 ozone season (depending on when this proposal is finalized). This would impact approximately 1,000 tons of identified reduction potential related to SNCR retrofit.

e. Installing New SCRs

Selective Catalytic Reduction (SCR) controls already exist on approximately 60% of the coal fleet in the linked states that would be subject to a FIP in this proposed rulemaking. Nearly every pulverized coal unit larger than 100 MW built in the last 30 years has installed this control, which is generally required for Best Available Control Technology (BACT) purposes. Other than circulating fluidized bed coal units which can achieve a comparably low emissions rate without this technology, the EPA identifies this emissions reduction measure for coal steam units greater than or equal to 100 MW. SCR is widely available for existing coal units of this size and can provide significant emissions reduction potential, with removal efficiencies of up to 90 percent. The EPA limited its consideration of SCR technology to steam units greater than or equal to 100 MW. The costs for retrofitting a plant smaller than 100 MW with SCR increase rapidly due to a lack of economy of scale.[153]

The amount of time needed to retrofit an EGU with new SCR extends beyond the 2023 ozone season. The EPA proposes that a strategy of retrofitting new SCR on a fleetwide, regional scale is available by, but no earlier than, the 2026 ozone season. Similar to the SNCR retrofits discussed above, the EPA evaluated potential emissions reductions and associated costs from this control technology, as well as the impacts and need for this emissions control strategy, at the earliest point in time when their installation could be achieved. In the past, the EPA has found the amount of time to retrofit a single EGU with new SCR, depending on the regulatory program under which such control may be required, may vary between approximately 2 and 4 years depending on site-specific engineering considerations and on the number of installations being considered. This includes steps for engineering review, construction permit, operating permit, and control technology installation (including fabrication, pre hookup, control hookup, and testing). EPA's assessment of installation procedures suggests as little as 21 months may be needed for a single SCR at an individual plant and 36 months at a single plant with multiple boilers. EPA's assessment of units with SCR retrofit potential indicate the majority fall into this first classification, *i.e.,* a single SCR at a power plant. Given that some of the assumed SCR retrofit potential occurs at plants with multiple units identified with retrofit potential, and given the total volume of SCR retrofit capacity being implemented across the region, The EPA is proposing 36 months as an appropriate time frame to accommodate both instances as well as scheduling necessities attributable to the regional-scale nature of the program.

---

[151] *See* EGU NO_X Mitigation Strategies Proposed Rule TSD for additional discussion.

[152] A month-by-month evaluation of SNCR installation is discussed in EPA's NO_X Mitigation Strategies Proposed Rule TSD and in EPA's "Engineering and Economic Factors Affecting the Installation of Control Technologies for Multipollutant Strategies". The analysis in this exhibit estimates the installation period from contract award as within a 10–13-month timeframe. The exhibit also indicates a 16-month timeframe from start to finish, inclusive of pre-contract award steps of the engineering assessment of technologies and bid request development. The timeframe cited for installation of SNCR at an individual source in this action is consistent with this more complete timeframe estimated by the analysis in the exhibit.

[153] IPM Model-Updates to Cost and Performance for APC Technologies. SCR Cost Development Methodology for Coal-fired Boilers. February 2022.

Further, the EPA notes that it has previously determined in the context of ozone transport that regional scale implementation of SCRs at numerous EGUs is achievable in 36 months. *See* 63 FR 57356, 57447–50 (October. 27, 1998). The EPA has at times also found up to 39–48 months to be an appropriate installation timeframe for regionwide actions when the EPA is evaluating multiple installations at multiple locations.[154] However, as discussed in greater detail in Section VII.A in this proposed rule, the EPA now recognizes that the *Wisconsin* decision invalidated the standard under which the EPA had been evaluating appropriate compliance timeframes for purposes of assessing interstate transport under the good neighbor provision when the Agency had concluded a 39–48 month timeframe to install SCR was appropriate.

The Agency examined the cost for retrofitting a coal unit with new SCR technology, which typically attains controlled NO_X rates of 0.05 lbs/mmBtu or less. These updates are further discussed in the EGU NO_X Mitigation Strategies Proposed Rule TSD.[155] Based on the characteristics of coal units of 100 MW or greater capacity that do not have post-combustion NO_X control technology, the EPA estimated a weighted-average representative SCR cost of $11,000 per ton.[156]

The 0.05 lb/mmBtu emission rate performance assumption for new SCR retrofits is supported by historical data and third party independent review by pollution control engineering and consulting firms. The EPA first examined unit-level emission rate data for coal-fired units that had a relatively recent SCR installation (within the last 10 years). These SCR retrofits reflect the most recent vintage of the pollution control technology applied to the power sector and are representative of new SCR retrofit capability. Although regulatory requirements or economic incentives were not necessarily in place during this time period for these SCRs to operate at their full potential, the EPA found that half of these units had still demonstrated a seasonal emission rate of 0.05 lb/mmBtu or lower and 78 percent had demonstrated this rate on a monthly basis. The best performing 10 percent of these SCRs were demonstrating seasonal emission rates of 0.036 lb/mmBtu during this time.

While the EPA identified the 0.05 lb/mmBtu performance assumption consistent with historical data, these performance levels are also informed and consistent with the Agency's IPM modeling assumptions used for more than a decade. These modeling assumptions are based on input from leading engineering and pollution control consulting entities. Most recently, these data assumptions were affirmed and updated in the summer of 2021 and included in the docket for this rulemaking. The EPA relies on a global firm providing engineering, construction management, and consulting services for power and energy with expertise in grid modernization, renewable energy, energy storage, nuclear power, and fossil fuels. Their familiarity with state-of-the art pollution controls at power plants derives from experience providing comprehensive project services—from consulting, design, and implementation to construction management, commissioning, and operations/maintenance. This review and update supported the 0.05 lb/mmBtu performance assumption as a representative emission rate for new SCR across coal types.

The EPA performed an assessment for oil/gas steam units in which it evaluated the nationwide performance of those units with SCR technology. For these units, the EPA tabulated EGU NO_X ozone season emissions data from 2009 through 2021 and calculated an average NO_X ozone season emissions rate across the fleet of oil- and gas-fired EGUs with SCR for each of these years. The EPA identified the third lowest year which yielded an SCR performance rate of 0.03 lb/mmBtu as representative of performance for this retrofit technology applied to this type of EGU. Next, the EPA evaluated the emissions and operational characteristics for the existing oil/gas steam fleet lacking SCR technology. EPA's analysis indicated that the majority of reduction potential (approximately 76 percent) from these units occurred at units greater than or equal to 100 MW and that were emitting more than 150 tons per ozone season (*i.e.,* approximately 1 ton per day). Moreover, the cost of reductions for units falling below these criteria increased significantly. Therefore, the EPA identified the portion of the oil/gas steam fleet meeting this criteria as representative of the SCR retrofit reduction potential.[157] For this segment of the oil/gas steam units lacking post-combustion NO_X control technology, the EPA estimated a weighted-average representative SCR cost of $7,700 per ton.

f. Generation Shifting

Finally, EPA evaluates emissions reduction potential from generation shifting across the representative dollar per ton levels estimated for the emissions controls considered above. As the cost of emitting NO_X increases, it becomes increasingly cost-effective for units with lower NO_X rates to increase generation, while units with higher NO_X rates reduce generation. Because the cost of generation is unit-specific, this generation shifting occurs incrementally on a continuum. Consequently, there is more generation shifting at higher cost NO_X-control levels.

It is reasonable for the EPA to quantify and include the emissions reduction potential from generation shifting at cost levels that are representative of the emissions control technologies evaluated in the multi-factor analysis, because all EGUs that would be regulated by this proposed rule participate in highly coordinated, interconnected systems where generation shifting will inevitably occur in response to pollution control requirements. If the EPA did not account for such emissions reduction potential in its analysis at Step 3, seeking emissions reductions from pollution control measures at higher-NO_X-emitting EGUs would still incentivize generation shifting toward lower-NO_X-emitting EGUs when sources comply under the remedy mechanism established in Step 4, and the corresponding reductions in emissions achieved through such generation shifting would potentially substitute for some of the emissions reductions intended through control operation and installation, potentially lessening the implementation of those mitigation strategies. Generation shifting treatment and results are discussed in greater detail in the EGU NO_X Mitigation Strategies Proposed TSD and the Ozone Transport Policy Analysis Proposed Rule TSD.

---

[154] *See, e.g.,* CSAPR Close-Out, 83 FR 65878, 65895 (December 21, 2018). *See also* Final Report: Engineering and Economic Factors Affecting the Installation of Control Technologies for Multipollutant Strategies, EPA–600/R–02/073 (Oct. 2002), available at *https://nepis.epa.gov/Adobe/PDF/P1001G0O.pdf.*

[155] As noted in that TSD, approximately half of the recent SCR retrofits (*i.e.,* installed in the last 10 years) have demonstrated an emission rate across the ozone season below 0.05 lb/mmBtu, even absent a requirement or strong incentive to operate at that level in many cases.

[156] This cost estimate is representative of coal units lacking any post-combustion control. A subset of units within the universe of coal sources with SCR retrofit potential, but that have an existing SNCR technology in place would have a weighted average cost that falls above this level, but still cost effective. See the EGU NO_X Mitigation Strategies Proposed Rule TSD for more discussion.

[157] The EPA used a 3 year average of 2019–2021 reported ozone season emissions to derive a tons per ozone season value representative for each covered oil/gas steam unit.

The EPA notes that its treatment of generation shifting here is consistent with the prior CSAPR rulemakings and is grounded on the same statutory authority. *See, e.g.,* 76 FR 48208, 48280 (August 8, 2011). As the EPA explained in the CSAPR Update:[158]

> The good neighbor provision requires state and federal plans implementing its requirements to ''prohibit[ ] . . . *any source or other type of emissions activity within the State* from emitting any air pollutant in *amounts* which will'' significantly contribute to nonattainment or interfere with maintenance of the NAAQS in any other state. CAA section 110(a)(2)(D)(i)(I) (emphasis added). . . . [T]he statute does not limit the EPA's authority under the good neighbor provision to basing regulation only to control strategies for individual sources. The statute authorizes the state or EPA in promulgating a plan to prohibit emissions from ''any source or other type of emissions activity within the State'' that contributes (as determined by EPA) to the interstate transport problem with respect to a particular NAAQS. This broad statutory language shows that Congress was directing the states and the EPA to address a wide range of entities and activities that may be responsible for downwind emissions. However, this provision is silent as to the type of emissions reduction measures that the states and the EPA may consider in establishing emissions reduction requirements, and it does not limit those measures to individual source controls. . . . The EPA reasonably interprets this provision to authorize consideration of a wide range of measures to reduce emissions from sources, which is consistent with the broad scope of this provision, as noted immediately above.

81 FR 74545.[159] The EPA continued to apply this same understanding in the Revised CSAPR Update. *See* 86 FR 23054, 23095–97 (April 30, 2021); *see also* 85 FR 68964, 68992–93 (October 30, 2020).

The EPA requests comment on the suite of mitigation technologies for EGUs described earlier and assessed in the determination of significant contribution. The EPA requests comment on the assumed performance or emissions rate of the technology, the representative cost, and the timing for installation.[160] Additionally, the EPA requests comment on whether other EGU ozone-season NO_X Mitigation technologies should be required to eliminate significant contribution. For instance, the EGU NO_X Mitigation Strategies Proposed Rule TSD discusses certain mitigation technologies that have been applied to ''peaking'' units (small, low capacity factor gas combustion turbines often only operating during periods of peak demand). To the extent that any of these sources meet the applicability requirements and are covered in the Group 3 trading program under this proposed rulemaking, they would have an incentive to reduce emissions consistent with the ozone season NO_X allowance price. The EPA has not identified determinative evidence that there are additional meaningful, cost-effective upwind reductions from these emission controls that are not already being addressed by state rules. EPA's analysis discussed in the EGU NO_X Mitigation Strategies Proposed Rule TSD highlights that there are 32 units emitting more than 10 tons per year on average for the 2019–2021 ozone seasons and lacking combustion controls or more advanced controls (totaling approximately 1,000 tons of ozone season NO_X emissions in 2021). Some of the units in the limited inventory are subject to state requirements delivering additional reductions by 2023. Moreover, the EPA analysis suggested $25,000–$30,000 per ton estimates for dry low NO_X burners or ultra-low NO_X burners at these units, and over $100,000 per ton for SCR retrofit at some combustion turbines. Therefore, the EPA is not proposing any additional reductions from new controls for inclusion in its combustion control or retrofit technology breakpoints. Although the EPA is not proposing a mitigation technology for this type of unit, it requests comment on the potential emissions reductions and cost from such sources in covered states that do not currently have mitigation requirements for such sources.

2. Non-EGU NO_X Mitigation Strategies

a. Determining Non-EGU NO_X Reduction Potential

The number of different industries and emissions unit categories and types, as well as the total number of emissions units that comprise the universe of non-EGU sources, makes it challenging to define a single method to identify appropriate control technologies, measures, or strategies and resulting impactful emissions reductions. Because of these challenges, the EPA adopted a different approach for assessing non-EGU NO_X emissions reduction potential than the approach for EGUs described in the preceding section. To assess emissions reduction potential from non-EGUs, the EPA first performed a screening assessment to identify those industries that could have the greatest air quality impact at downwind receptors. This was followed by an assessment estimating annual NO_X emissions reduction potential at specific cost thresholds for each of the most impactful industries. Next, the EPA estimated the reductions in ozone concentrations resulting from the emissions reductions for each industry in each of the 27 linked upwind states. As described later, the results indicate that the most impactful industries fall into two tiers based on the estimated reductions in ozone concentrations associated with the NO_X emissions reductions.

The Agency incorporated air quality information as a first step in an analytical framework to help determine potentially impactful industries to focus on for further assessing potential controls, emissions reduction potential, air quality improvements, and costs. The EPA developed the analytical framework using inputs from the air quality modeling for the Revised CSAPR Update for 2023,[161] as well as the projected 2023 annual emissions inventory from the 2016v2 emissions platform that was used for the air quality modeling for this proposed rule. Additional information on the analytical framework is presented in the Non-EGU Screening Assessment memorandum available in the docket.

Using the Revised CSAPR Update modeling for 2023, the EPA identified upwind states linked to downwind nonattainment or maintenance receptors using the 1 percent of the NAAQS threshold criterion, which is 0.7 ppb (1 percent of a 70 ppb NAAQS). In 2023 there were 27 linked states for the 2015 ozone NAAQS: Alabama, Arkansas, California, Delaware, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Oregon, Pennsylvania, Tennessee, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming.

[158] The EPA discussed its legal authority for and the technical viability of generation shifting as a method of emissions reduction under the good neighbor provision in the CSAPR Update. *See especially* 81 FR 74504, 74545–47; *see also* CSAPR Update Response to Comment Document at 546–550 (legal authority); *id.* 528–533 (technical feasibility). *See* Final Revised CSAPR Update, 86 FR 23096–97.

[159] The EPA also noted in the CSAPR Update, ''Interpreting the Good Neighbor Provision to be sufficiently broad to authorize reliance on generation shifting is also consistent with the legislative history for the 1970 CAA Amendments. The Senate Report stated that to achieve the NAAQS, '[g]reater use of natural gas for electric power generation may be required,' S. Rep. No. 91–1196 at 2.'' 81 FR 74545 n.141.

[160] The feasibility of the timetable for emissions reductions from both EGUs and non-EGUs is further addressed in Section VII.A of this proposed rule.

[161] The EPA used the Revised CSAPR Update air quality modeling for this screening assessment because the air quality modeling for this proposed rule was not completed in time to support the assessment.

To analyze non-EGU emissions units, the EPA aggregated the underlying projected 2023 emissions inventory data into industries defined by 4-digit NAICS. Then for linked states, the EPA followed the 2-step process below:

Step 1—The EPA identified industries whose potentially controllable emissions have the greatest ppb impact on downwind air quality, and

Step 2—The EPA determined which of the most impactful industries and emissions units had the most emissions reductions that would make meaningful air quality improvements at the downwind receptors at a marginal cost threshold the EPA determined using underlying control device efficiency and cost information.

To estimate the contributions by industry, defined by 4-digit NAICS, at each downwind receptor the EPA used the 2023 state-receptor specific Revised CSAPR Update ppb/ton values and the Revised CSAPR Update calibration factors used in the air quality assessment tool (AQAT) for control analyses in 2023.[162] The EPA focused on assessing emissions units that emit greater than 100 tons per year (tpy) of NO_X.[163] By limiting the focus to potentially controllable emissions, well-controlled sources that still emit greater than 100 tpy are excluded. Instead, the focus is on uncontrolled sources or sources that could be better controlled at a reasonable cost. As a result, reductions from any industry identified by this process are more likely to be achievable and to lead to air quality improvements.

From this information, the EPA prepared a summary with the estimated total, maximum, and average contributions from each industry and the number of receptors with contributions greater than or equal to 0.01 ppb from each industry.[164] The EPA used this information to identify breakpoints in the data to determine which industries to focus on for the next steps in its analysis, as described in the Non-EGU Screening Assessment memorandum.

A review of the maximum contribution data indicated that the EPA should focus the assessment of NO_X reduction potential and cost primarily on four industries. These industries each (1) have a maximum contribution to any one receptor of greater than 0.10 ppb and (2) contribute greater than or equal to 0.01 ppb to at least 10 receptors. The four industries identified below comprise the ''Tier 1'' non-EGU industries.

- Pipeline Transportation of Natural Gas
- Cement and Concrete Product Manufacturing
- Iron and Steel Mills and Ferroalloy Manufacturing
- Glass and Glass Product Manufacturing

In addition to these industries, the maximum contribution data suggests including five additional industries as a second tier in the assessment. These industries each either have (1) a maximum contribution to any one receptor greater than or equal to 0.10 ppb but contribute greater than or equal to 0.01 ppb to fewer than 10 receptors, or (2) a maximum contribution less than 0.10 ppb but contribute greater than or equal to 0.01 ppb to at least 10 receptors. The five industries identified below comprise the ''Tier 2'' non-EGU industries.

- Basic Chemical Manufacturing
- Petroleum and Coal Products Manufacturing
- Metal Ore Mining
- Lime and Gypsum Product Manufacturing
- Pulp, Paper, and Paperboard Mills

For additional discussion of the contribution information, see Appendix A of the Non-EGU Screening Assessment memorandum included in the docket for this proposed rulemaking.

Next, to identify an annual cost threshold for evaluating potential emissions reductions in the Tier 1 and Tier 2 industries, the EPA used the Control Strategy Tool (CoST),[165] the Control Measures Database (CMDB),[166] and the projected 2023 emissions inventory to prepare a listing of potential control measures, and costs, applied to non-EGU emissions units in the projected 2023 emissions inventory. Using these data, the EPA plotted curves for Tier 1 industries, Tier 2 industries, Tier 1 and 2 industries, and all industries at $500 per ton increments. Figure 1 on page 4 of the Non-EGU Screening Assessment memorandum, which is available in the docket for this proposed rulemaking, indicates there is a ''knee in the curve'' at approximately $7,500 per ton (all non-EGU cost estimates in the assessment and presented in the rest of this section are in 2016 dollars). The EPA used this marginal cost threshold to further assess potential control strategies, estimated emissions reductions, air quality improvements, and costs from the potentially impactful industries. Note that controls and related emissions reductions are available at several estimated cost levels up to the $7,500 per ton threshold. (These costs do not include monitoring, recordkeeping, reporting, or testing costs.)

Next, using the marginal cost threshold of $7,500 per ton, to estimate emissions reductions and costs the EPA processed the CoST run using the maximum emissions reduction algorithm,[167] with known controls.[168] The EPA identified controls for non-EGU emissions units in the Tier 1 and Tier 2 industries that cost up to $7,500 per ton. The EPA then calculated air quality impacts associated with the estimated reductions for the 27 linked states in 2023 using the following steps.

1. The EPA binned the estimated reductions by 4-digit NAICS code into the Tier 1 and Tier 2 industries.

2. The EPA used the 2023 state-receptor specific Revised CSAPR Update ppb/ton values and the Revised CSAPR Update calibration factors used in the AQAT for control analyses in 2023. The EPA multiplied the estimated

[162] The calibration factors are receptor-specific factors. For the Revised CSAPR Update, the calibration factors were generated using 2016 base case and 2023 base case air quality model runs. These receptor-level ppb/ton factors are discussed in the Ozone Transport Policy Analysis Final Rule TSD found here: *https://www.epa.gov/sites/default/files/2021-03/documents/ozone_transport_policy_analysis_final_rule_tsd_0.pdf.*

[163] In the non-EGU emissions reduction assessment prepared for the Revised Cross State Air Pollution Rule Update (*https://www.regulations.gov/document/EPA-HQ-OAR-2020-0272-0014*), The EPA reviewed emissions units with >150 tpy of NO_X emissions. In this assessment, EPA broadened the scope to include emissions units with greater than or equal to 100 tpy of NO_X emissions.

[164] The EPA chose to include in the Non-EGU NO_X reduction potential analysis those industries that contribute at least 0.01 ppb to a downwind receptor in order to focus the analysis on the most impactful industries. The 0.01 criterion is based on an analysis of the distribution and relative magnitude of contributions from 41 industries, as identified in the Non-EGU Screening Assessment memorandum. From this analysis the EPA determined that 0.01 ppb provides a meaningful conservative breakpoint for screening out non-impactful industries from the Non-EGU analysis in this proposed rule. Details on this analysis that provides the basis for using 0.01 ppb can be found in the Non-EGU Screening Assessment memorandum.

[165] Further information on CoST can be found at the following link: *https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-analysis-modelstools-air-pollution.*

[166] The CMDB is available at the following link: *https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-analysis-modelstools-air-pollution.*

[167] The maximum emissions reduction algorithm assigns to each source the single measure (if a measure is available for the source) that provides the maximum reduction to the target pollutant. For more information, *see* the CoST User's Guide available at the following link: h*ttps://www.cmascenter.org/cost/documentation/3.7/CoST%20User's%20Guide/.*

[168] Known controls are well-demonstrated control devices and methods that are currently used in practice in many industries. Known controls do not include cutting edge or emerging pollution control technologies.

non-EGU reductions by the ppb/ton values and by the receptor-specific calibration factor to estimate the ppb impacts from these emissions reductions.

Next, because boilers represent the majority emissions units in the Tier 2 industries for which there were controls that cost up to $7,500 per ton, the EPA further targeted emissions reductions and air quality improvements in Tier 2 industries by identifying potentially impactful industrial, commercial, and institutional (ICI) boilers. To identify potentially impactful boilers, using the projected 2023 emissions inventory in the linked upwind states, the EPA identified a universe of boilers with greater than 100 tpy NO_X emissions that had contributions at downwind receptors.[169] [170] The EPA refined the universe of boilers to a subset of impactful boilers by sequentially applying the three criteria below to each boiler. This approach is similar to the overall analytical framework and was tailored for application to individual boilers.[171]

- Criterion 1—Estimated maximum air quality contribution at an individual receptor of greater than or equal to 0.0025 ppb or estimated total contribution across downwind receptors of greater than or equal to 0.01 ppb.
- Criterion 2—Controls that cost up to $7,500 per ton.
- Criterion 3—Estimated maximum air quality improvement at an individual receptor of greater than or equal to 0.001 ppb.

Lastly, the EPA updated its analytical framework to the 2026 analytic year by which the EPA is proposing non-EGU controls be installed across the Tier 1 and Tier 2 industries and various emissions unit types. The EPA concluded, based on the most recent information available from the CSAPR Update Non-EGU TSD,[172] that controls on all of the non-EGU emissions units cannot be installed by the 2023 ozone season. The EPA prepared the non-EGU screening assessment for the year 2026 by generally applying the analytical framework detailed above, with some modifications. The updated screening assessment results for 2026 are discussed in Section VI.C.2 [173] of this proposed rule. Specifically, the EPA

- Retained the impactful industries identified in Tier 1 and Tier 2, the $7,500 cost per ton threshold, and the methodology for identifying impactful boilers;
- Modified the framework to address challenges associated with using the projected 2023 emissions inventory by using the 2019 emissions inventory; [174] and
- Updated the air quality modeling data by using the most recent air quality modeling data for this proposal for the analytic year 2026.

3. Other Stationary Sources NO_X Mitigation Strategies

As part of its analysis for this proposed rule, the EPA also reviewed whether NO_X mitigation strategies for any other stationary sources may be appropriate. In this section, the EPA discusses three classes of units that have historically been excluded from our interstate air transport programs: (1) Units less than or equal to 25 MW, (2) solid waste incineration units, and (3) cogeneration units. EPA's initial assessment does not lead it to propose inclusion of the units less than or equal to 25 MW, but the EPA is requesting comment on any particular units within this category that may offer cost-effective reduction potential. The EPA is also taking comment on and considering whether to include emissions limitations for solid waste incineration units (many of which are less than 25 MW) in a final rule, as discussed later. For cogeneration units previously exempted from EGU emissions budgets established through ozone interstate transport rules, the EPA has not identified a basis for inclusion in this proposal.

The EPA has not historically identified substantial emissions reduction or air quality gains from corresponding reductions from these segments of units and has therefore not considered inclusion of these segments of stationary sources in its federal programs for interstate transport.

However, given the need to implement a full remedy to address interstate transport, the more stringent 2015 ozone NAAQS of 70 ppb, and the extended period of time for which the EPA projects upwind contribution to persistent nonattainment and maintenance problems, the EPA is requesting comment on whether sources within these three segments—units serving a generator equal or smaller than 25 MW, cogeneration units, and solid waste incineration units—could merit inclusion within EPA's proposed NO_X mitigation strategy in this rule. Specifically, the EPA requests comment on available NO_X mitigation technologies, NO_X emissions rate performance, total potentially available NO_X reductions, installation timing, cost, air quality impacts, source-specific information, and any other information that could inform a control determination specific to these three types of units. The EPA provides an assessment of these three segments, their emissions control opportunities, and potential air quality benefits below. Additional considerations are further discussed in the EGU NO_X Mitigation Strategies Proposed Rule TSD.

a. Units Less Than or Equal to 25 MW

The EPA has historically not included control requirements for emissions for units less than or equal to 25 MW for three primary reasons: Low potential reductions, relatively high cost per ton of reduction, and high monitoring and other compliance burdens. In the January 11, 1993, Acid Rain permitting rule, the EPA provided for a conditional exemption from the emissions reduction, emitting, and emissions monitoring requirements of the Acid Rain Program for new units having a nameplate capacity of 25 MWe or less that burn fuels with a sulfur content no greater than 0.05% by weight, because of the *de minimis* nature of their potential SO_2, CO_2 and NO_X emissions. *See* 63 FR 57484. The NO_X SIP Call identified these as *Small Point Sources.* For the purposes of that rulemaking, the EPA considered electricity generating boilers and turbines serving a generator 25 MWe or less, to be small point sources. The EPA noted that the collective emissions from small sources

[169] The EPA used the 2023fj non-EGU point source inventory files from the 2016v2 emissions platform.

[170] Maryland, Missouri, Nevada, and Wyoming did not have boilers with >100 tpy NO_X emissions.

[171] For the impactful boiler assessment, the estimated air quality contributions and improvements were not based on modeling of individual emissions units or emissions source sectors. The air quality estimates were derived by using the 2023 state/receptor specific Revised CSAPR Update ppb/ton values and the Revised CSAPR Update calibration factors used in AQAT. The results indicate a level of precision not supported by the underlying air quality modeling. The results were intended to provide an indication of the relative impact across sources.

[172] Final Technical Support Document (TSD) for the Final Cross-State Air Pollution Rule for the 2008 Ozone NAAQS, Assessment of Non-EGU NO_X Emissions Controls, Cost of Controls, and Time for Compliance Final TSD (''CSAPR Update Non-EGU TSD''), August 2016, available at *https://www.epa.gov/csapr/assessment-non-egu-NOX-emission-controls-cost-controls-and-time-compliance-final-tsd.*

[173] The non-EGU screening assessment is not intended to be, nor take the place of, a unit-specific detailed engineering analysis that evaluates the feasibility of retrofits for the emissions units, potential controls, and related costs. For more detailed discussion of these issues, *see* Section VII.C of this proposed rule and the Non-EGU Sectors TSD included in the docket.

[174] The EPA determined that the 2019 inventory was appropriate because it provided a more accurate prediction of potential near-term emissions reductions. *See* the Non-EGU Screening Assessment memorandum, available in the docket, for a discussion of the challenges associated with using the projected 2023 emissions inventory.

were relatively small and the administrative burden to the states and regulated entities of controlling such sources was likely to be considerable. As a result, the rule did not assume reductions from those sources in state emissions budgets requirements (63 FR 57402). Similar size thresholds have been incorporated in subsequent transport programs such as CAIR and CSAPR. As these sources were not identified as having cost-effective reductions and so were not included in those programs, they were also exempted from certain reporting requirements and the data for these sources is, therefore, not of the same caliber as that of covered larger sources.

EPA's preliminary survey of current data, compared to this initial justification, does not appear to offer a compelling reason to depart from this past practice by requiring emission reductions from these small EGU sources as part of this rule. For instance, as explained in the EGU NO_X Mitigation Strategies Proposed Rule TSD, EPA has evaluated the costs of SCR retrofits at small EGUs using its Retrofit Cost Analyzer and found that such controls become markedly less cost-effective at lower levels of generating capacity. This analysis concluded that, after controlling for all other unit characteristics, the dollar per ton cost for a SCR retrofit increases by about a factor of 2.5 when moving from a 500 MW to a 10 MW unit, and a factor of 8 when moving to a 1 MW unit.[175] Moreover, the EPA estimates that under 6% of nationwide EGU emissions come from units less than 25 MW and not covered by current applicability criteria due to this size exemption threshold. Therefore, the EPA is not proposing to require any emissions reductions from these units, but the EPA requests comment on whether there are any cost-effective reductions and corresponding air quality benefits to nonattainment or maintenance receptors from any units within this segment.

b. Municipal Solid Waste Units

The EPA seeks comment on whether NO_X emissions reductions should be sought from municipal solid waste combustor units (MWCs) to address interstate ozone transport. As noted below, MWCs emit substantial amounts of NO_X, and some states have required emissions limits for these facilities that are more stringent than the federal requirements contained within EPA's new source performance standard (NSPS) for this industry. These more stringent limits, if applied broadly to the 26 states included in this proposed FIP action, would create an additional means of reducing NO_X emissions.

MWCs burn garbage and other non-hazardous solid material using a variety of combustion techniques. Section 2.1, Refuse Combustion, of the EPA emissions factor reference document AP–42[176] contains a description of the seven different combustion process technologies most commonly used in the industry. A copy of Section 2.1 of AP–42 is included within the Docket for this proposed rule. These seven combustion processes are as follows: Mass burn waterwall, mass burn rotary waterwall, mass burn refractory wall, refuse-derived fuel-fired, fluidized bed, modular starved air, and modular excess air. Section 2.1 of AP–42 contains detailed process descriptions of each of these MWC processes. During the combustion process, a number of pollutants are produced, including NO_X, which forms through oxidation of nitrogen in the waste and from fixation of nitrogen in the air used to burn the waste. NO_X emissions from MWCs are typically released through tall stacks which enables the emissions to be transported long distances.

Most MWCs are cogeneration facilities that recover heat from the combustion process to power a turbine to produce electricity. According to a 2018 report from the Energy Recovery Council,[177] 72 of the 75 operating MWC facilities in the U.S. produce electricity from heat captured from the combustion process. The electrical output of MWCs is relatively small compared to the EGUs that will be regulated per the proposed requirements of Section VII.B of this proposal, with most MWCs having an electrical output capacity of less than 25 MW. The Non-EGU Sectors TSD located in the Docket identifies the electrical output capacity for MWC units that produce electricity as reflected in EPA's NEEDS database.

However, despite their relatively small electricity-generating potential, NO_X emissions from MWCs located in the transport states identified in this proposal are substantial. According to the EPA's NEI database, MWCs emitted 19,222 tons of NO_X in 2017 in the ten states included in this proposal that contain them. Table 8 of the Non-EGU Sectors TSD contains a list of MWC facilities located within the states included in this proposal along with their NO_X emissions as reported to the NEI.

The EPA has promulgated NO_X emissions limits for large MWCs, defined as those that process 250 tons of municipal solid waste per day or more at 40 CFR part 60, subpart Cb and 40 CFR part 60, subpart Eb. Subpart Cb is applicable to MWCs that commenced construction on or before September 20, 1994, while Subpart Eb is applicable to MWCs that commenced construction, modification, or reconstruction after September 20, 1994. The NO_X limits for subpart Cb are found within Tables 1 and 2 of 40 CFR 60.39b and range from 165 to 250 ppm depending on the combustor design type. The NO_X limits for Subpart Eb are found at 40 CFR 60.52b(d) and are 180 ppm during a unit's first year of operation and drop to 150 ppm afterwards, applicable across all combustor types. These limits correspond to NO_X emissions rates of 0.31 and 0.26 lbs/MMBtu, respectively.

Section 182(b)(2) and (f) of the CAA requires states with ozone nonattainment areas classified as Moderate or higher to adopt regulations with control requirements representing reasonably available control technology (RACT) for major sources of VOCs and NO_X. Sections 184(b)(1)(B) and 182(f) of the Act require RACT requirements be adopted in all areas included within the Ozone Transport Region (OTR). Due primarily to the NO_X RACT requirement, many states within the Northeast located within the OTR have adopted NO_X emissions limits for MWCs that are more stringent than what would otherwise be required by EPA's NSPS or the emissions guideline for these units. For example, the Montgomery County Resource Recovery Facility in Maryland is required to meet a NO_X RACT limit of 140 ppm (at 7 percent oxygen) on a 24-hour block average. Additionally, MWC facilities located in Virginia operated by Covanta, Inc., are required to meet a NO_X RACT limit of 110 ppm (at 7 percent oxygen) on a 24-hour basis, and a limit of 90 ppm (at 7 percent oxygen) on an annual average basis.[178] The 110 ppm limit equates to a limit of 0.19 lbs/MMBtu.

The Ozone Transport Commission (OTC) issued a report entitled ''Municipal Waste Combustor Workgroup Report'' in June of 2021. The

[175] Preliminary estimate based on representative coal units with starting NO_X rate of 0.2 lb/mmBtu, 10,000 BTU/kwh, and assuming 80 percent reduction.

[176] ''AP–42, Fifth Edition Compilation of Air Pollutant Emissions Factors, Volume 1: Stationary Point and Area Sources'', available at: *https://www.epa.gov/air-emissions-factors-and-quantification/ap-42-compilation-air-emissions-factors.*

[177] ''2018 Directory of Waste to Energy Facilities''; Energy Recovery Council.

[178] The NO_X permit limits for the Montgomery County facility and the Virginia facilities can be found within the OTC's Municipal Waste Combustor Workgroup Report included within the Docket for this proposed rule.

report is included within the docket for this proposal.[179] The report notes that MWCs are a significant source of NO_X emissions in the OTR, releasing approximately 22,000 tons of NO_X from facilities within 9 OTR states in 2018. The report summarizes the results of a literature review of state-of-the-art NO_X controls that have been successfully installed and concludes that significant reductions could be achieved using several different technologies described in the report, primarily via combustion modifications made to MWC units already equipped with SNCR. The MWC workgroup evaluated the emissions reduction potential from two different control levels, one based on a NO_X concentration in the effluent of 105 to 110 ppm, and another based on a limit of 130 ppm. The workgroup's findings were that a control level of 105 parts per million by volume, dry (ppmvd) on a 30-day average basis and a 110 ppmvd on a 24-hour averaging period would reduce NO_X emissions from MWCs by approximately 7,300 tons annually, and that a limit of 130 ppmvd on a 30 day-average could achieve a 4,000 ton reduction. The report notes that 8 MWC units exist that are already subject to permit limits of 110 ppm, 7 in Virginia, and one in Florida. Studies evaluating MWCs similar in design to the large MWCs in the OTR found NO_X reductions could be achieved at costs ranging from $2,900 to $6,600 per ton of NO_X reduced. Based on the findings of this report, the Commissioners of the states within the OTR adopted a resolution to develop a recommendation for emissions reductions from MWCs during their June 15, 2021, annual public meeting.[180]

In light of the above, the EPA requests comment on whether NO_X limits for MWCs located in the states covered by this proposed rule should be included in the final FIP. Specifically, if NO_X controls are included in the final FIP, the EPA requests comment on the following issues:

- What NO_X emissions limit and averaging time should MWCs be required to meet, and in particular should the EPA adopt emissions rates of 105 ppmvd on a 30-day averaging basis and 110 ppmvd on a 24-hour averaging basis?
- What types of NO_X control technology could be used to reduce NO_X emissions at MWCs, and in particular should the EPA adopt the combustion control modifications made to units with previously installed SNCR identified by the MWC workgroup?
- Whether there is information that would call into question the OTC workgroup's estimated cost of controls for reducing NO_X emissions from MWCs of $2,900 to $6,600 per ton, and, assuming that range is accurate, whether there is any justification for not requiring these controls in light of their relative cost-effectiveness and total level of reductions available, which compare favorably with the proposed EGU and non-EGU control strategies?
- If the final FIP includes emissions reduction requirements for MWCs, should any mechanism be available by which a particular MWC source could seek to establish that meeting the required emissions limits is not feasible?
- Is there any evidence that retrofit of MWC emissions controls would take longer to implement than the 2026 ozone season?
- Would it be appropriate to rely on existing testing, monitoring, recordkeeping, and reporting requirements for MWCs under the applicable NSPS or other requirements?

c. Cogeneration Units

Consistent with prior transport rules, fossil fuel-fired boilers and combustion turbines that produce both electricity and useful thermal energy (generally referred to as ''cogeneration units'') and that meet the applicability criteria to be included in the CSAPR NO_X Ozone Season Group 3 Trading Program would be subject to the emissions reduction requirements established in this rulemaking for EGUs. However, those applicability criteria—which the EPA is not proposing to alter in this rulemaking (*see* Section VII.B.3 of this proposed rule)—exempt some cogeneration units from coverage as EGUs under the trading program. The EPA is proposing that fossil fuel-fired boilers and combustion turbines that produce both electricity and useful thermal energy and that do not meet the applicability criteria to be included in the CSAPR NO_X Ozone Season Group 3 Trading Program as EGUs would not be subject to any other emissions reduction requirements under this rulemaking.

Cogeneration systems can offer considerable environmental benefit as they often require less fuel to produce a given energy output. The average efficiency of fossil-fuel fired power plants in the United States is 33 percent. This means that two-thirds of the energy used to produce electricity at most power plants in the United States is wasted in the form of heat discharged to the atmosphere. By recovering wasted heat, combined heat and power (CHP) systems at cogeneration units typically achieve total system efficiencies of 60 to 80% for producing electricity and useful thermal energy. Some systems achieve efficiencies approaching 90%. This increased efficiency allows the same level of energy use to be achieved with fewer criteria-pollutant and greenhouse gas emissions. Additionally, these systems increase the reliability of access to electrical power for the facilities they serve and reduce the need for electricity from regional power plants and their associated transmission and distribution networks.

According to information contained in the EPA's Combined Heat and Power Partnership's document ''Catalog of CHP Technologies'',[181] there are 4,226 CHP installations in the U.S. providing 83,317 MWe of electrical capacity. Over 99% of the installations are powered by 5 equipment types, those being reciprocating engines (52 percent), boilers/steam turbines (17 percent), gas turbines (16 percent), microturbines (8 percent), and fuel cells (4 percent). The majority of the electrical capacity is provided by gas turbine CHP systems (64 percent) and boiler/steam turbine CHP systems (32 percent). The various CHP technologies described above are available in a large range of sizes, from as small as 1 kilowatt reciprocating engine systems to as large as 300 megawatt gas turbine powered systems.

NO_X emissions from fuel cell powered systems are negligible, and NO_X emissions from rich-burn reciprocating engine, gas turbine, and microturbine systems are low, ranging from 0.013 to 0.05 lbs/mmBTU. NO_X emissions from lean-burn reciprocating engine systems and gas-powered steam turbines systems range from 0.1 to 0.2 lbs/mmBTU. The highest NO_X emitting CHP units are solid fuel-fired boiler/steam turbine systems which emit NO_X at rates ranging from 0.2 to 1.2 lbs/mmBTU. A preliminary assessment from EPA's IPM Summer 2021 Reference Case model suggest that cogeneration units exempted from current EPA EGU transport programs due to such classification are projected to account for approximately 5% of nationwide summer NO_X emissions in 2023.[182]

[179] This report is also available at *https://otcair.org/upload/Documents/Reports/20210624%20OTC%20SAS%20MWC%20report%20final.pdf.*

[180] *See* ''Notice of Proposed rules Taken by Ozone Transport Commission At Annual Public Meeting, June 15, 2021'' included in the Docket for this proposed rule.

[181] This document is available at*: https://www.epa.gov/sites/default/files/2015-07/documents/catalog_of_chp_technologies.pdf.*

[182] *https://www.epa.gov/airmarkets/results-using-epas-power-sector-modeling-platform-v6-summer-2021-reference-case.* The EPA notes that cogeneration units not exempted from EGU Air programs are included in the EPA assessment of

Under the proposed rule (consistent with prior CSAPR rulemakings), certain cogeneration units would be exempt from coverage under the CSAPR NO_X Ozone Season Group 3 Trading Program as EGUs. Specifically, the trading program regulations include an exemption for a unit that qualifies as a cogeneration unit throughout the later of 2005 or the first 12 months during which the unit first produces electricity and continues to qualify through each calendar year ending after the later of 2005 or that 12-month period and that meets the limitation on electricity sales to the grid. In order to meet the trading program's definition of ''cogeneration unit'' under the regulations, a unit (*i.e.,* a fossil-fuel-fired boiler or combustion turbine) must be a topping-cycle or bottoming-cycle type that operates as part of a ''cogeneration system.'' A cogeneration system is defined as an integrated group of equipment at a source (including a boiler, or combustion turbine, and a generator) designed to produce useful thermal energy for industrial, commercial, heating, or cooling purposes and electricity through the sequential use of energy. A topping-cycle unit is a unit where the sequential use of energy results in production of useful power first and then, through use of reject heat from such production, in production of useful thermal energy. A bottoming-cycle unit is a unit where the sequential use of energy results in production of useful thermal energy first, and then, through use of reject heat from such production, in production of useful power. In order to qualify as a cogeneration unit, a unit also must meet certain efficiency and operating standards in 2005 and each year thereafter. The electricity sales limitation under the exemption is applied in the same way whether a unit serves only one generator or serves more than one generator. In both cases, the total amount of electricity produced annually by a unit and sold to the grid cannot exceed the greater of one-third of the unit's potential electric output capacity or 219,000 MWh. This is consistent with the approach taken in the Acid Rain Program (40 CFR 72.7(b)(4)), where the cogeneration-unit exemption originated.

The EPA is requesting comment on the proposal to exempt cogeneration units meeting the above criteria from any emissions reduction requirements under this proposed rulemaking. The EPA also requests comment on the alternative of requiring fossil fuel-fired boilers in the non-EGU industries identified earlier (Section VI.B.2.a of this proposed rule) that serve electricity generators and that qualify for an exemption from inclusion in the CSAPR NO_X Ozone Season Group 3 Trading Program as EGUs to instead meet the same emissions standards, if any, that would apply under this proposed rulemaking to fossil fuel-fired boilers at facilities in the same non-EGU industries that do not serve electricity generators. These proposed emissions standards are set forth in Section VII.C.5 of this proposed rule. Cogeneration units at these facilities are in the non-EGU industries identified in EPA's non-EGU screening assessment for this proposal (although potential emissions reductions from such cogeneration units were not specifically quantified in the assessment). Under this alternative approach, to the extent these industries have otherwise been determined in this proposal to significantly contribute to nonattainment or interfere with maintenance, the EPA would find that cogeneration units in these industries should not be excluded from EPA's overall NO_X mitigation strategy.

4. Mobile Source NO_X Mitigation Strategies

Under a variety of CAA programs, the EPA has established federal emissions and fuel quality standards that reduce emissions from cars, trucks, buses, nonroad engines and equipment, locomotives, marine vessels, and aircraft (*i.e.,* ''mobile sources''). Because states are generally preempted from regulating new vehicles and engines with certain exceptions (*see generally* CAA sections 209, 177), mobile source emissions are primarily controlled through EPA's federal programs. The EPA has been regulating mobile source emissions since it was established as a federal agency in 1970, and all mobile source sectors are currently subject to NO_X emissions standards. The EPA factors these standards and associated emissions reductions into its baseline air quality assessment in good neighbor rulemaking, including in this proposed rule. These data are factored into EPA's analysis at Steps 1 and 2 of the 4-step framework. As a result of this long history, NO_X emissions from onroad and nonroad mobile sources have substantially decreased (73 percent and 57 percent since 2002, for onroad and nonroad, respectively) [183] and are predicted to continue to decrease into the future as newer vehicles and engines that are subject to the most recent, stringent standards replace older vehicles and engines.[184]

For example, in 2014, the EPA promulgated new, more stringent emissions and fuel standards for light-duty passenger cars and trucks.[185] The fuel standards took effect in 2017, and the vehicle standards phase in between 2017 and 2025. Other EPA actions that are continuing to reduce NO_X emissions include the Heavy-Duty Engine and Vehicle Standards and Highway Diesel Fuel Sulfur Control Requirements (66 FR 5002; January 18, 2001); the Clean Air Nonroad Diesel Rule (69 FR 38957; June 29, 2004); the Locomotive and Marine Rule (73 FR 25098; May 6, 2008); the Marine Spark-Ignition and Small Spark-Ignition Engine Rule (73 FR 59034; October 8, 2008); the New Marine Compression-Ignition Engines at or Above 30 Liters per Cylinder Rule (75 FR 22895; April 30, 2010); and the Aircraft and Aircraft Engine Emissions Standards (77 FR 36342; June 18, 2012).

The EPA is currently developing a new regulatory effort to reduce NO_X and other pollution from heavy-duty trucks (known as the Cleaner Trucks Initiative), as described in the January 21, 2020, Advance Notice of Proposed Rulemaking (85 FR 3306). Heavy-duty vehicles are the largest contributor to mobile source emissions of NO_X and will be one of the largest mobile source contributors to ozone in 2025.[186] Reducing heavy-duty vehicle emissions nationally would improve air quality where the trucks are operating as well as downwind. As required by CAA section 202(a)(3)(A) of the Act, the EPA will be proposing NO_X emissions standards that ''reflect the greatest degree of emissions reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.'' Section 202(a)(3)(C) of the Act requires that standards apply for no less than 3 model years and apply no earlier than 4 years after promulgation.

The EPA's existing regulatory program for mobile sources will

---

EGU reduction potential in Section VI.B.1 of this proposed rule.

continue to reduce NO_X emissions into the future, and the EPA is currently taking active steps to ensure that these NO_X reductions occur. The CAA prohibits tampering with emissions controls, as well as manufacturing, selling, and installing aftermarket devices intended to defeat those controls. The EPA currently has a National Compliance Initiative called ''Stopping Aftermarket Defeat Devices for Vehicles and Engines,'' which focuses on stopping the manufacture, sale, and installation of hardware and software specifically designed to defeat required emissions controls on onroad and nonroad vehicles and engines.

C. Control Stringencies Represented by Cost Threshold ($ per Ton) and Corresponding Emissions Reductions

1. EGU Emissions Reduction Potential by Cost Threshold

For EGUs, as discussed in Section VI.A of this proposed rule, the multi-factor test considers increasing levels of uniform control stringency in combination with considering total NO_X reduction potential and corresponding air quality improvements. The EPA evaluated EGU NO_X emissions controls that are widely available (described previously in Section VI.B.1 of this proposed rule), that were assessed in previous rules to address ozone transport, and that have been incorporated into state planning requirements to address ozone nonattainment.

The EPA evaluated the EGU sources within the state of California and found there were no covered coal steam sources greater than 100 MW that would have emissions reduction potential according to EPA's assumed EGU SCR retrofit mitigation technologies.[187] The EGUs in the state are sufficiently well-controlled resulting in the lowest fossil-fuel emission rate and highest share of renewable generation among the 26 states examined at Step 3. EPA's Step 3 analysis, including analysis of the emissions reduction factors from EGU sources in the state, therefore resulted in no additional emission reductions required to eliminate significant contribution from any EGU sources in California.

The tables below summarize the emissions reduction potentials (in ozone season tons) from these emissions controls across the affected jurisdictions. Table VI.C.1–1 focuses on near-term emissions controls while Table VI.C.1–2 includes emissions controls with extended implementation timeframes.

TABLE VI.C.1–1—EGU OZONE-SEASON EMISSIONS AND REDUCTION POTENTIAL (tons)—2023

State	Baseline 2023 OS NO_X	Reduction potential (tons) for varying levels of technology inclusion			
		SCR optimization	SCR optimization + combustion control upgrades *	SCR/SNCR optimization + combustion control upgrades	SCR/SNCR optimization + combustion control upgrades + generation shifting

2. Non-EGU Emissions Reduction Potential—Cost Threshold Up to $7,500/ton

The EPA used the updated non-EGU screening assessment for 2026 to estimate emissions reduction potential from the Tier 1 and Tier 2 industries and non-EGU emissions units. The EPA used CoST to identify emissions units, emissions reductions, and associated compliance costs to evaluate the effects of potential non-EGU emissions control measures and technologies. CoST is designed to be used for illustrative control strategy analyses (*e.g.,* NAAQS regulatory impact analyses) and not for unit-specific, detailed engineering analyses. These estimates from CoST identify proxies for (1) non-EGU emissions units that have emissions reduction potential, (2) potential controls for and emissions reductions from these emissions units, and (3) control costs from the potential controls on these emissions units. The cost estimates do not include monitoring, recordkeeping, reporting, or testing costs.

To prepare the non-EGU screening assessment for 2026, the EPA applied the analytical framework detailed in Section VI.B.2 of this proposed rule. The assessment includes emissions units from the Tier 1 industries and impactful high-emitting boilers in Tier 2 Industries. Using the latest air quality modeling for 2026, the EPA identified upwind states linked to downwind nonattainment or maintenance receptors using the 1% of the NAAQS threshold criterion, or 0.7 ppb. In 2026 there are 23 linked states for the 2015 ozone NAAQS: Arkansas, California, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming.

The EPA re-ran CoST with known controls, the CMDB, and the 2019 emissions inventory.[188] The EPA specified CoST to allow replacing an existing control if a replacement control is estimated to be greater than 10% more effective than the existing control. The EPA did not replace an existing control if the 2019 emissions inventory indicated the presence of that control, even if the CMDB reflects a greater control efficiency for that control. Also, the EPA removed six facilities from consideration because they are subject to an existing consent decree, are shut down, or will shut down by 2026. For additional detail on the six facilities removed, see Appendix B in the Non-EGU Screening Assessment memorandum. Table VI.C.2–1 summarizes the estimated reductions, total ppb improvements across all receptors, and annual total and average annual costs (in 2016 dollars) and Table VI.C.2–2 below summarizes the estimated reductions by state.

[188] The EPA determined that the 2019 inventory was appropriate because it provided a more accurate prediction of potential near-term non-EGU emissions reductions.

TABLE VI.C.2–1—ESTIMATED EMISSIONS REDUCTIONS (OZONE SEASON TONS), TOTAL PPB IMPROVEMENTS ACROSS ALL DOWNWIND RECEPTORS, AND COSTS

Tier	Ozone season emissions reductions (East/West)	Total PPB improvement across all downwind receptors	Annual total cost (million 2016$) (average annual cost/ton)	Industries (# of emissions units >100 tpy in identified industries)
Tier 1 Industries with Known Controls that Cost up to $7,500/ton.	41,153 (37,972/3,181)	4.352	$356.6 ($3,610)	Cement and Concrete Product Manufacturing (47) Glass and Glass Product Manufacturing (44) Iron and Steel Mills & Ferroalloy Manufacturing (39) Pipeline Transportation of Natural Gas (307).
Tier 2 Industry Boilers with Known Controls that Cost up to $7,500/ton.	6,033 (5,965/68)	0.809	54.2 (3,744)	Basic Chemical Manufacturing (17) Petroleum and Coal Products Manufacturing (10) Pulp Paper, and Paperboard Mills (25).

TABLE VI.C.2–2—ESTIMATED EMISSIONS REDUCTIONS (OZONE SEASON TONS) BY UPWIND STATE * **

State	2019 OS NO_X emissions	OS NO_X reductions
AR	8,265	1,654

Total	322,793	47,187

* In the non-EGU screening assessment, EPA estimated emissions reduction potential from the non-EGU industries and emissions units. The estimated emissions reductions by state in the table above are from the non-EGU screening assessment; for additional results from the non-EGU screening assessment, including estimated reductions by state and by industry, please see the Non-EGU Screening Assessment memorandum available in the docket.

** In the assessment, EPA used CoST to identify emissions units, emissions reductions, and associated compliance costs to evaluate the effects of potential non-EGU emissions control measures and technologies. CoST is designed to be used for illustrative control strategy analyses (*e.g.,* NAAQS regulatory impact analyses) and not for unit-specific, detailed engineering analyses. These estimates from CoST identify proxies for (1) non-EGU emissions units that have emissions reduction potential, (2) potential controls for and emissions reductions from these emissions units, and (3) control costs from the potential controls on these emissions units. The cost estimates do not include monitoring, recordkeeping, reporting, or testing costs.

In this section, EPA provides a summary of the control technologies applied and their average costs across all of the non-EGU emissions units included in the screening assessment. This summary reflects one approach to organizing this information, which the Agency finds reasonable based on the information available for this proposal. As discussed in Section VI.B.2 of this proposed rule, the number of different industries and emissions unit categories and types present a challenge to defining a single method to identify appropriate control technologies, measures or strategies, and related costs across non-EGU emissions units. Because of the number of industries and emissions unit types, the available information does not easily allow grouping estimated emissions reductions by cost per ton threshold for a few control technologies, measures, or strategies. Nonetheless, Table VI.C.2–3 below provides a summary of estimated reductions and average cost per ton values by control technology across all non-EGU emissions units included in the non-EGU screening assessment. The summary reflects fourteen control technologies applied by CoST across all emissions units in the non-EGU screening assessment. The average cost per ton values range from $585 to $6,300 per ton, all of which are below the marginal cost per ton threshold of $7,500 per ton. Note that the average cost per ton values are in 2016 dollars and reflect simple averages and not a percentile or other representative cost values from a distribution of cost estimates.

The Non-EGU Screening Assessment memorandum includes two other summaries of estimated reductions and average cost per ton values by technology across non-EGU emissions units. First, the memorandum includes a summary by control technology as applied across non-EGU emissions units grouped by the Tier 1 industries and impactful boilers in Tier 2 industries, which given this further disaggregation reflects 18 control technologies across the tiers applied by CoST. Second, the memorandum includes a summary by control technology across non-EGU emissions units grouped by the seven individual Tier 1 and 2 industries, which given this disaggregation reflects 26 control technologies across the industries applied by CoST.

TABLE VI.C.2–3—ESTIMATED EMISSIONS REDUCTIONS (OZONE SEASON TONS), ANNUAL TOTAL COST, AND AVERAGE COST PER TON BY CONTROL TECHNOLOGY ACROSS ALL NON-EGU EMISSIONS UNITS

Control technology	Ozone season emissions reductions	Average cost per ton
Adjust Air to Fuel Ratio and Ignition Retard	212	$2,393
Layered Combustion	12,706	5,457
Low NO_X Burner	231	3,773
Low NO_X Burner and Flue Gas Recirculation	200	4,288
Natural Gas Reburn	284	2,703
Non-Selective Catalytic Reduction	147	585
Non-Selective Catalytic Reduction or Layered Combustion	6,359	4,743
Oxygen Enriched Air Staging	52	764
SCR + DLN Combustion	136	6,301
Selective Catalytic Reduction	12,239	2,543
Selective Catalytic Reduction and Steam Injection	929	3,787
Selective Non-Catalytic Reduction	8,076	1,485
Ultra-Low NO_X Burner	1,670	2,890
Ultra-Low NO_X Burner and Selective Catalytic Reduction	3,946	4,114

Refer to the Non-EGU Screening Assessment memorandum for additional 2026 screening assessment results—including by industry and by state, estimated emissions reductions and costs, as well as by industry, emissions source groups, control technologies, number of emissions units, estimated ozone season reductions, and annual total cost.

D. Assessing Cost, EGU and Non-EGU NO_X Reductions, and Air Quality

To determine the emissions that are significantly contributing to nonattainment or interfering with maintenance, the EPA applied the multi-factor test to EGUs and non-EGUs separately, considering for each the relationship of cost, available emissions reductions, and downwind air quality impacts. Specifically, for each sector, the EPA proposes a determination regarding the appropriate level of uniform NO_X control stringency that would collectively eliminate significant contribution to downwind nonattainment and maintenance receptors. The EPA also evaluated whether the proposed rule resulted in possible over-control scenarios by evaluating if an upwind state is linked solely to downwind air quality problems that could have been resolved at a lower cost threshold, or if an upwind state could have reduced its emissions below the 1 percent air quality contribution threshold at a lower cost threshold.

1. EGU Assessment

For EGUs, the EPA examined the emissions reduction potential associated with each EGU emissions control technology (presented in Section VI.C.1 of this proposed rule) and its impact on the air quality at downwind receptors. Specifically, EPA identified and assessed the projected average air quality improvements relative to the base case and whether these improvements are sufficient to shift the status of receptors from projected nonattainment to maintenance or from maintenance to attainment. Combining these air quality factors, costs, and emissions reductions, the EPA identified a control stringency for EGUs that results in substantial air quality improvement from emissions controls that are available in the timeframe for which air quality problems at downwind receptors persist. For all affected jurisdictions, this control stringency reflects, at a minimum, the optimization of existing post-combustion controls and installation of state-of-the-art NO_X combustion controls, which are widely available at a representative marginal cost of $1,800 per ton. EPA's evaluation also shows that the effective emissions rate performance across affected EGUs consistent with realization of these mitigation measures does not over-control upwind states' emissions relative to either the downwind air quality problems to which they are linked at Step 1 or the 1 percent contribution threshold that triggers further evaluation at Step 3 of the 4-step framework for the 2015 ozone NAAQS.

Similarly, the EPA also identified installation of new SCR post-combustion controls at coal steam sources greater than or equal to 100 MW and for a more limited portion of the oil/gas steam fleet that had higher levels of emissions as components of the required control stringency. These SCR retrofits are widely available by the 2026 ozone season at $11,000 and $7,700 per ton respectively. For all but 3 of the affected states (Alabama, Delaware, and Tennessee—which are no longer linked in 2026 at Steps 1 and 2 in EPA's base case air quality modeling), EPA's evaluation also shows that the effective emissions rate performance across EGUs consistent with realization of these mitigation measures does not over-control upwind states' emissions in 2026 relative to either the downwind air quality problems to which they are linked at Step 1 or the 1 percent contribution threshold that triggers further evaluation at Step 3 of the 4-step framework for the 2015 ozone NAAQS (*see* the Ozone Transport Policy Analysis Proposed Rule TSD for details).

To assess downwind air quality impacts for the nonattainment and maintenance receptors identified in Section V.D of this proposed rule, the EPA evaluated the air quality change at that receptor expected from the progressively more stringent upwind EGU control stringencies that were available for that time period in upwind states linked to that receptor. This assessment provides the downwind ozone improvements for consideration and provides air quality data that is used to evaluate potential over-control situations.

To assess the air quality impacts of the various control stringencies at downwind receptors for the purposes of Step 3, the EPA evaluated changes resulting from the emissions reductions associated with the identified emissions controls in each of the upwind states, as well as assumed corresponding reductions of similar stringency in the downwind state containing the receptor to which they are linked. By applying these emissions reductions to the state containing the receptor, the EPA assumes that the downwind state will implement (if it has not already) an emissions control stringency for its sources that is comparable to the upwind control stringency identified here. Consequently, The EPA is accounting for the downwind state's share of a nonattainment or maintenance problem as a part of the over-control evaluation.[189]

For this assessment, the EPA used an ozone air quality assessment tool (ozone AQAT) to estimate downwind changes in ozone concentrations related to upwind changes in emissions levels. The EPA focused its assessment on the years 2023 and 2026 as they pertain to the last years for which ozone season emissions data can be used for purposes of determining attainment for the Moderate (2024) and Serious (2027) attainment dates. For each EGU emissions control technology, the EPA first evaluated the magnitude of the change in ozone concentrations at the nonattainment and maintenance receptors for each relevant year (*i.e.,* 2023 and 2026). Next, the EPA evaluated whether the estimated change in concentration would resolve the receptor's nonattainment or maintenance concern by lowering the average or maximum design values, respectively, below 71 ppb. For a complete set of estimates, see the Ozone Transport Policy Analysis Proposed Rule TSD or the ozone AQAT excel file.

For 2023, the EPA evaluated potential air quality improvements at the downwind receptors outside of California associated with available EGU emissions control technologies in that timeframe. The EPA determined for the purposes of Step 3 that the average air quality improvement at the receptors relative to the engineering analytics base case was 0.11 ppb for emissions reductions commensurate with optimization of existing SCRs/SNCRs and combustion control upgrades. The EPA determined for the purposes of Step 3 that one receptor in Clark County, Nevada switches from maintenance to attainment with these mitigation strategies in place. Table VI.D.1–1 summarizes the results of EPA's Step 3 evaluation of air quality improvements at these receptors using AQAT.

For 2026, the EPA determined that the average air quality improvement at these receptors relative to the engineering analytics base case was 0.43 ppb for emissions reductions commensurate with optimization of existing SCRs/SNCRs, combustion control upgrades, and new post-combustion control (SCR and SNCR) retrofits at eligible units are assumed to be implemented. The EPA determined for the purposes of Step 3 that in 2026, all but one of the receptors are expected to remain nonattainment or maintenance across these control stringencies, with one receptor in Douglas County, Colorado switching from maintenance to attainment with these mitigation strategies in place.[190] Table VI.D.1–2 summarizes the results of EPA's Step 3 evaluation of air quality improvements at the receptors included in the AQAT analysis. For more information about how this assessment was performed and the results of the analysis for each receptor, refer to the Ozone Transport Policy Analysis Proposed Rule TSD and to the Ozone AQAT included in the docket for this rule.

TABLE VI.D.1–1—AIR QUALITY AT THE 29 RECEPTORS IN 2023 FROM EGU EMISSIONS CONTROL TECHNOLOGIES[a b]

Monitor ID No.	State	County	Average DV (ppb)		Max DV (ppb)	
			Baseline (engineering analysis)	SCR/SNCR optimization + LNB upgrade	Baseline (engineering analysis)	SCR/SNCR optimization + LNB upgrade

490110004	Utah	Davis	73.65	73.59	75.91	75.85

[189] For EGUs, this analysis for the Connecticut receptors shows no EGU reduction potential from the emissions reduction measures identified given that state's already low-emitting fleet; however, EGU reductions were identified in Colorado and these reductions were included in the over-control analysis.

[190] As in prior rules, for the purpose of defining significant contribution at Step 3, the EPA evaluated air quality changes resulting from the application of the emissions reductions in only those states that are linked to each receptor as well as the state containing the receptor. By applying reductions to the state containing the receptor, the EPA ensures that it is accounting for the downwind state's fair share. This method holds each upwind state responsible for its fair share of the downwind problems to which it is linked. Reductions made by other states in order to address air quality problems at other receptors do not increase or decrease this share. The air quality impacts on design values that reflect the emissions reductions in all linked states and the health and climate benefits from this proposal are discussed in Section IX of this proposed rule.

TABLE VI.D.1–1—AIR QUALITY AT THE 29 RECEPTORS IN 2023 FROM EGU EMISSIONS CONTROL TECHNOLOGIES [a] [b]—Continued

Average AQ Change Relative to Base (ppb)						0.11
Total PPB Change Across All Receptors Relative to Base [c]						3.08

Table Notes:

[a] These results reflect the inclusion of all identified LNB upgrade potential. Some of which will be implemented in 2023 state emissions budgets, and some be implemented in 2024 state emissions budgets (for those states not included in the Revised CSAPR Update).

[b] The EPA notes that the design values reflected in tables VI.D.1–1 and 2 correspond to the engineering analysis EGU emissions inventory that was used in AQAT to determine state-level baseline emissions and reductions at Step 3. These tools are discussed in greater detail in the Ozone Transport Policy Analysis Proposed Rule TSD.

[c] The cumulative ppb change only shows the aggregate change across all problematic receptors (some of which are located within close proximity to one another) in this part of the Step 3 analysis. Section IX of this proposed rule provides a more complete picture of the air quality impacts of the proposed rule.

Figures 1 and 2 to Section VI.D.1, included in Appendix G of the Ozone Transport Policy Analysis Proposed Rule TSD available in the docket for this rulemaking, illustrate the air quality improvement relative to the estimated representative cost associated with the previously identified emissions control technologies. The graphs show improving air quality at the downwind receptors as emissions reductions commensurate with the identified control technologies are assumed to be implemented. Figure 1 to Section VI.D.1 [191] reflects emissions reductions commensurate with optimization of existing SNCRs and SCRs. Figure 2 to Section VI.D.1 [192] reflects emissions reductions commensurate with installation of new post combustion controls (mainly SCRs) layered on top of the emissions reduction potential from the technologies represented in Figure 1 to Section VI.D.1.[193] The graphic, and underlying AQAT receptor-by-receptor analysis demonstrates that air quality continues to improve at downwind receptors as EPA examines increasingly stringent EGU NO_X control

[191] Included in Appendix G of the Ozone Transport Policy Analysis Proposed Rule TSD, which is available in the docket for this rulemaking.

[192] Included in Appendix G of the Ozone Transport Policy Analysis Proposed Rule TSD, which is available in the docket for this rulemaking.

[193] Included in Appendix G of the Ozone Transport Policy Analysis Proposed Rule TSD, which is available in the docket for this rulemaking.

technologies. While all major technology breakpoints identified in Sections VI.B and VI.C of this proposed rule show continued air quality improvements at problematic receptors and at cost and technology choice levels that are commensurate with mitigation strategies that are proven to be widely available and implemented, EPA's quantification and application of those breakpoints reflect certain exclusions to: (1) Preserve this consistency with widely observed mitigation measures in states, and (2) remove any retrofit assumptions at marginal units that would have much higher dollar per ton representative cost and little or no air quality benefit. For instance, the EPA does not define the SCR retrofit breakpoint ($11,000 per ton) to include retrofit application at steam units less than 100 MW or at oil/gas steam units emitting at less than 150 tons per ozone season. The emissions reductions from these potential categories of measures are small and do not constitute additional ''breakpoints'' in EPA's estimation. They would entail much higher dollar per ton costs, going beyond what is widely observed in the fleet. This careful calibration of technology breakpoints through exclusion of measures that are clearly not cost-effective in terms of air quality benefit allows for the identification of an EGU strategy that is an appropriate reflection of those readily available and widely implemented emissions reduction strategies that will have meaningful downwind air quality impact.

Moreover, these technologies (and representative cost) are demonstrated ozone pollution mitigation strategies that are widely practiced across the EGU fleet and are of comparable stringency to emissions reduction measures that many downwind states have already instituted. The coal SCR retrofit measures driving the majority of the emissions reductions in this action not only reflect industry best practice, but they also reflect prevailing practice among EGUs. More than 60% of the existing coal capacity already has this technology in place. For nearly 25 years, all new coal-fired EGUs that commenced construction have had SCR (or equivalent emissions rates). The 1997 proposed amendments to subpart Da revised the NO_X standard based on the use of SCR. The NO_X SIP Call (promulgated in 1998) established emissions reduction requirements premised on extensive SCR installation (142 units) and incentivized well over 40 GWs of SCR retrofit in the ensuing years.[194] Similarly, the Clean Air Interstate Rule established emissions reductions requirements in 2006 that assumed another 58 units (15 GW) would be installed in the ensuing years among just 10 states, and an even greater volume of capacity chose SCR retrofit measures in the wake of finalizing that action.[195]

Basing emission reduction requirements for EGUs on SCR retrofits is also consistent with regulatory approaches adopted by states, which—particularly in downwind areas more impacted by ozone transport contribution from upwind state emissions—have already adopted SCR-based standards as part of stringent NO_X control programs. Regulatory programs that impose stringent Reasonably Available Control Technology (RACT) requirements on all major power plants and Lowest Achievable Emission Rate (LAER) standards on all new major sources of NO_X have resulted in remaining coal sources in states along the Northeast Corridor such as Connecticut, Delaware, New Jersey, New York, and Massachusetts all being retrofitted with SCR.[196] The Maryland Code of Regulations requires coal fired sources to operate existing SCR controls or install SCR controls by specified dates.[197] Programs like North Carolina's Clean Smokestacks Act and Colorado's Clean Air, Clean Jobs Act have also required or prompted SCR retrofits on units.[198] Unit-level Best Available Retrofit Technology (BART) requirements for the first Regional Haze planning period also determined SCR retrofits (and corresponding emissions rates) were cost-effective controls for a variety of sources in the U.S.[199]

As shown in Figure 1 to Section VI.D.1,[200] the majority of EGU emissions reduction potential and associated air quality improvements estimated for 2023 occurs from optimization of existing SCRs, with some additional reductions from installation of state-of-the-art combustion controls at the same representative cost threshold. At the slightly higher representative cost threshold of $1,800 per ton, there is some additional air quality improvement from optimization of existing SNCRs. These measures taken together represent the control stringency at which near-term incremental EGU NO_X reduction potential and corresponding downwind ozone air quality improvements are maximized. This evaluation shows that EGU NO_X reductions for each of the near-term emissions control technologies are available at reasonable cost and that these reductions provide meaningful improvements in downwind ozone concentrations at the identified nonattainment and maintenance receptors. Figure 1 to Section VI.D.1[201] highlights (1) the continuous connection between identified emission reduction potential and downwind air quality improvement across the range of near-term mitigation measures assessed, and (2) the cost-effective availability of these reductions and corresponding air quality improvements.

Additional considerations that are unique to EGUs provide additional support for EPA's proposal to include SCR and SNCR optimization as part of the identified near-term control stringency, including:

- These controls are already installed and available for operation on these units;
- they are on average already partially operating, but not necessarily optimized;
- the reductions are available in the near-term (during ozone seasons when the problematic receptors are projected to persist), including by the 2023 ozone season aligned with the Moderate area attainment date; and
- these sources are already covered under the existing CSAPR NO_X Ozone Season Group 2 or Group 3 Trading Programs or the Acid Rain Program and thus have the monitoring, reporting, recordkeeping, and all other necessary elements of compliance with the trading program already in place.

The majority of emissions reduction potential and associated air quality improvements estimated for 2026 occur from retrofitting uncontrolled steam sources with post-combustion controls. At the representative cost threshold of $11,000 per ton, there are significant additional air quality improvements from emissions reductions commensurate with installation of new SCRs and SNCRs. These measures taken together with the near-term emissions reduction measures described

previously represent the level of control stringency in 2026 at which incremental EGU NO_X reduction potential and corresponding downwind ozone air quality improvements are maximized. This evaluation shows that EGU NO_X reductions for each of the emissions control technologies are available at reasonable cost and that these reductions can provide improvements in downwind ozone concentrations at the identified nonattainment and maintenance receptors.

The EPA finds that the control stringency that reflects optimization of existing SCRs and SNCRs, installation of state-of-the-art combustion controls, and the retrofitting of new post combustion controls at the coal and oil/gas steam capacity described previously results in nearly 90,000 tons of NO_X reduction (approximately 43 percent of the 2026 baseline level) for the 22 linked states in 2026 subject to a FIP for EGUs, which will deliver notable air quality improvements across all transport-impacted receptors and assist in fully resolving one downwind air quality problem for the 2015 ozone NAAQS. Figure 2 to Section VI.D.1 [202] demonstrates the continuous connection between identified emissions reduction potential and downwind air quality improvement across the range of mitigation measures assessed in 2026. At no point do the additional emission mitigation measures examined here fail to produce corresponding downwind air quality improvements.

The EPA is proposing that emissions reductions commensurate with the full operation of all existing post-combustion controls (both SCRs and SNCRs) and state-of-the-art combustion control upgrades constitute the Agency's selected control stringency for EGUs for those states linked to downwind nonattainment or maintenance in 2023. For those states also linked in 2026, the EPA is determining that the appropriate EGU control stringency also includes emissions reductions commensurate with the retrofit of SCR at coal steam units of 100 MW or greater capacity (excepting circulating fluidized bed units), new SNCR on coal steam units of less than 100 MW capacity and circulating fluidized bed units, and SCR on oil/gas steam units greater than 100 MW that have historically emitted at least 150 tons of NO_X per ozone season.

As noted previously in Section VI.B of this proposed rule and in the EGU NO_X Mitigation Strategies Proposed Rule TSD, the EPA considered other methods of identifying mitigation measures (*e.g.,* SCRs on smaller units, combustion control upgrades on combustion turbines, SCRs on combustion turbines). The emission reductions from these potential categories of measures do not constitute additional ''technology breakpoints'' in EPA's estimation, but rather reflect a different tier of assessment where further mitigation measures are based on inclusion of smaller and/or different generator type of unit (rather than pollution control technology). Emissions reductions from these measures are relatively small and would entail much higher dollar per ton costs, going beyond what is widely observed in the fleet. Although these additional measures are not included in EPA's technology breakpoint analysis discussed above, the EPA did examine the cost, potential reductions, and air quality impact of these additional measures in a supplemental analysis to affirm that they do not merit inclusion in the proposed stringency for this action. Similar to prior rules, there is a notable ''knee-in-the-curve'' breakpoint if these additional measures are included in EPA's analysis. In other words, there are very little additional emissions reductions and air quality improvement at problematic receptors, and the cost associated with these measures increases substantially on a dollar per ton basis. The graphic below illustrates the significant loss in cost-effectiveness of reductions if these measures had been included in EPA's proposed stringency.[203]

This proposed determination regarding the appropriate level of control stringency for EGUs to eliminate significant contribution from upwind states finds that the amounts of NO_X emissions reduction achieved through these strategies at EGUs are necessary and cost-justified under the Step 3 multifactor analysis for as long as the strategies remain available to the sources. In other words, the EPA finds at Step 3 that so long as the identified NO_X emissions reduction controls are available and can be implemented (such as optimization of SCRs), they must be implemented, even as total NO_X emissions reductions on a mass basis decline. EPA's Step 3 finding is *not* limited to a determination of the mass-based reduction in emissions that the EPA determines is achievable for the covered EGU fleet under current operating conditions. Rather, the EPA finds at Step 3 that EGUs must continue to achieve NO_X emissions performance in the ozone season commensurate with the level of emissions control stringency the EPA determines appropriate under the multifactor test as set forth in this section. The stringency of the emissions budgets would simply reflect the stringency of the emissions control strategies and would do so more consistently over time than EPA's previous approach of computing emissions budgets for all future control periods at the time of the rulemaking. This retention of a constant degree of stringency over time in emissions budgets under a flexible trading program would not constitute over-control any more than the permanent imposition of emissions rate standards on individual sources at the time of the rulemaking would constitute over-control.

EPA acknowledges that this is an adjustment in its historical approach to eliminating significant contribution, although it is consistent with the evolution of the Agency's thinking as set forth in the Revised CSAPR Update. In CSAPR and the CSAPR Update, EPA established static budgets at Step 4 based on the selected level of control stringency at Step 3. EPA's experience with this approach has been that while the initial mass-based budgets are achieved and compliance targets are even exceeded, this leads to a loss in efficacy of the program as the incentive to reduce emissions declines over time. Some sources emit at higher levels or relax their operation of NO_X controls in response to the build-up of allowances available for compliance, even though EPA has concluded those controls are necessary to meet the statutory good neighbor requirements. This result is inconsistent with the statutory mandate to ''prohibit'' significant contribution and interference with maintenance of the NAAQS in other states, as evidenced most clearly in CAA section 126, which makes it unlawful for a source ''to *operate* more than three months after [a finding that the source emits or would emit in violation of the good neighbor provision] has been made with respect

[202] Included in Appendix G of the Ozone Transport Policy Analysis Proposed Rule TSD, which is available in the docket for this rulemaking.

[203] This is not to discount the potential effectiveness of these or other NO_X mitigation strategies outside the context of this rulemaking to address regional ozone transport on a nationwide basis. States and local jurisdictions may find such measures particularly impactful or necessary in the context of local attainment planning or other unique circumstances. Further, while the EPA proposes this rule as a complete remedy to the problem of interstate transport for the 2015 ozone NAAQS, the EPA has in the past recognized that circumstances may arise after the promulgation of remedies under CAA section 110(a)(2)(D)(i)(I) in which the exercise of further remedial authority against specific stationary sources or groups of sources under CAA section 126 may be warranted. *See* Response to Clean Air Act Section 126(b) Petition From Delaware and Maryland, 83 FR 50444, 50453–54 (Oct. 5, 2018).

to it.'' 42 U.S.C. 7426(c)(2) (emphasis added). Moreover, there is no policy justification at Step 3 for an upwind source to relax or cease operating its emissions controls simply because other sources of pollution have been reduced. In the Revised CSAPR Update, the EPA began to address this problem by establishing adjusted emissions budgets for each year from 2021 through 2025 based on information about the changing EGU fleet known at the time of promulgation of the rule. *See* 86 FR 23118. As discussed in Section VII.B of this proposed rule, the EPA is now implementing a more complete approach to eliminating significant contribution by imposing dynamic budget updates and banking restrictions to ensure that its selected control stringency at Step 3 continues to be implemented.

This approach at Step 4 is wholly consistent with EPA's findings at Step 3. This is best illustrated by comparing the trading program approach with the requirements the EPA could promulgate for EGUs based on an approach of assigning unit-specific emissions rate limitations. Under the latter approach, the EPA would assign an enforceable emissions rate to each EGU, based on the operation of the selected NO_X control strategy (*e.g.,* optimizing existing SCRs) that would apply in perpetuity. By continually adjusting budgets to ensure that emissions outcomes are achieved—and downwind air quality benefits are delivered—that are commensurate with the continuous operation of emissions controls at the selected control stringency at Step 3, the EPA is better aligning the implementation of the program at Step 4 with the level of emissions reductions from upwind sources that the EPA has determined is appropriate through the Step 3 multifactor analysis.[204] The EPA requests comment on its identified EGU control stringencies, including its consideration of the cost, air quality impacts, and timing of such mitigation strategies.

2. Non-EGU Assessment

The Agency prepared the non-EGU screening assessment for 2026 using the analytical framework detailed in Section VI.B.2 of this proposed rule. Using a $7,500/ton (in 2016 dollars) marginal cost threshold identified in the framework, the screening assessment used CoST with known controls, the CMDB, and the 2019 emissions inventory and estimated emissions reductions from emissions units in the Tier 1 industries and impactful boilers in the Tier 2 industries.

Using 2026 as the potential earliest date by which controls on emissions units in the Tier 1 industries and impactful boilers in the Tier 2 industries could be installed, the EPA assessed whether these emissions reduction controls should be required at Step 3 under its multi-factor test.

The EPA determined that, for 2026, the average air quality improvement at receptors relative to the EGU case when SCR post-combustion controls were installed was 0.18 ppb when Tier 1 non-EGU controls were applied and an additional 0.04 ppb when Tier 2 non-EGU controls were applied, based on the Step 3 analysis. The EPA determined for the purposes of Step 3 that all but 3 receptors remain nonattainment or maintenance after the application of these controls, with two receptors (one in Brazoria County, Texas and one in Kenosha County, Wisconsin) switching from maintenance to attainment with these non-EGU controls in place.

TABLE VI.D.2–2—AIR QUALITY AT RECEPTORS IN 2026 FROM NON-EGU INDUSTRIES

Monitor ID No.	State	County	Average DV (ppb)		Max DV (ppb)	
			Baseline (engineering analysis)	EGU SCR/SNCR optimization + LNB upgrade + SCR/SNCR retrofit + non-EGU Tier 1 + Tier 2	Baseline (engineering analysis)	EGU SCR/SNCR optimization + LNB upgrade + SCR/SNCR retrofit + non-EGU Tier 1 + Tier 2

551010020	Wisconsin	Racine	70.52	70.12	72.42	72.02
Average AQ Change Relative to Base (ppb)						0.64

[204] The EPA does not believe this adjustment in its Step 3 approach for EGUs, or its corresponding, improved approach to the trading program at Step 4—which, again, mimics the effect of permanent and enforceable unit-specific emissions limits—violates the prohibition on over-control. Our over-control analysis is set forth below in Section VI.D of this proposed rule, and the EPA proposes to find that there is no over-control at the proposed stringency (for both EGUs and non-EGUs) in any upwind state.

TABLE VI.D.2–2—AIR QUALITY AT RECEPTORS IN 2026 FROM NON-EGU INDUSTRIES—Continued

			Baseline (engineering analysis)	EGU SCR/ SNCR optimization + LNB upgrade + SCR/SNCR retrofit + non-EGU Tier 1 + Tier 2	Baseline (engineering analysis)	EGU SCR/SNCR optimization + LNB upgrade + SCR/SNCR retrofit + non-EGU Tier 1 + Tier 2
Total PPB Change Across All Receptors Relative to Base (ppb)						14.13

For more information about how this assessment was performed and the results of the analysis for each receptor, refer to the Ozone Transport Policy Analysis Proposed Rule TSD and to the Ozone AQAT included in the docket for this rule.

a. Request for Comment on Non-EGU Control Strategies and Measures

In the non-EGU screening assessment, the EPA used CoST, the CMDB, and the 2019 emissions inventory to assess emissions reduction potential from non-EGU emissions units in several industries. The EPA identified emissions units that were uncontrolled or that could be better controlled and then applied control technologies to estimate emissions reductions and costs. As noted previously, the cost estimates do not include monitoring, recordkeeping, reporting, or testing costs. Based on the available information, the EPA is proposing to require implementation of the non-EGU emissions reductions at Step 3 by the beginning of the 2026 ozone season. The EPA discusses the basis for this proposed compliance schedule in Section VII.A.2 of this proposed rule.

The EPA requests comment on certain estimates and assumptions in this proposal that may affect EPA's evaluation of the capital and annual costs of several potential control technologies. In particular, the EPA requests comment on whether ultra-low NO_X burners or low NO_X burners are generally considered part of the process or add-on controls for ICI boilers (and how process changes or retrofits to accommodate controls would affect the cost estimates). We request comment on our estimates regarding the effectiveness of low emissions combustion in controlling NO_X from RICE compared to other potential NO_X controls for these engines. We request comment on whether controls on ICI boilers and reciprocating IC engines are likely to be run all year (*e.g.,* 8,760 hours/year) or only during the ozone season.

The EPA notes that the non-EGU NO_X mitigation strategy in this proposed rule focuses on obtaining emissions reductions from non-EGU units that were quantitatively determined to have the most significant impacts on air quality improvements at the downwind nonattainment and maintenance receptors. However, the EPA requests comment on the merits of requiring non-EGU sources within the linked upwind states to meet specified technology-based control standards, such as the RACT SIP requirements outlined in CFR part 51 for non-EGU sources located in OTR states.

3. Combined EGU and Non-EGU Assessment

The EPA used the Ozone AQAT to evaluate the combined impact of these selected stringency levels for both EGUs and non-EGUs on all receptors remaining in the 2026 air quality modeling base case to inform the over-control analysis. EPA's evaluation demonstrated air quality improvement at the 22 remaining nonattainment or maintenance receptors outside of California (*see* Section V.D of this proposed rule for receptor details). The EPA estimated that the average air quality improvement at these receptors relative to the engineering analytics base case was 0.64 ppb for emissions reductions commensurate with optimization of existing SCRs/SNCRs, combustion control upgrades, application of new post-combustion control (SCR and SNCR) retrofits at eligible units, and all estimated emissions reductions from the Tier 1 industries and impactful boilers in the Tier 2 industries. Table VI.D.1–3 summarizes the results of EPA's Step 3 evaluation of air quality improvements at these receptors using AQAT. In summary, the collective application of these mitigation measures and emissions reductions continue to deliver downwind air quality improvements up until the most stringent thresholds identified. The health and climate benefits resulting from application of these measures (as described in the RIA) are estimated to exceed the costs, and the identified technologies reflect not only demonstrated best practices—but widely adopted best practices in the case of EGU retrofits.

TABLE VI.D.3–1—CHANGE IN AIR QUALITY REDUCTIONS AT RECEPTORS IN 2026 FROM PROPOSED EGU AND NON-EGU EMISSIONS REDUCTIONS [a b c]

Tier/technology	Ozone season emissions reductions	Total PPB change across all downwind receptors [d]	Average PPB change across all downwind receptors
EGU (SCR/SNCR optimization + LNB upgrade) + Gen shifting	26,250	1.53	0.07
EGU SCR/SNCR Retrofit + Gen shifting	63,883	7.89	0.36
Non-EGU (Tier 1)	41,153	3.89	0.18
Non-EGU (Tier 2)	6,033	0.82	0.04
Total		14.13	0.64

Table Notes:

[a] As in prior rules, for the purpose of defining significant contribution at Step 3, the EPA evaluated air quality changes resulting from the application of the emissions reductions in only those states that are linked to each receptor as well as the state containing the receptor. By applying reductions to the state containing the receptor, the EPA ensures that it is accounting for the downwind state's fair share. In addition, this method holds each upwind state responsible for its fair share of the downwind problems to which it is linked. Reductions made by other states in order to address air quality problems at other receptors do not increase or decrease this share. The air quality impacts on design values that reflect the emissions reductions in all linked states and the health and climate benefits from this proposal are discussed in Section IX of this proposed rule.

[b] The EPA notes that the design values reflected in Tables VI.D.1–1 and 2 correspond to the engineering analysis EGU emissions inventory used in AQAT to determine state-level baseline emissions and reductions at Step 3. These tools are discussed in greater detail in the Ozone Transport Policy Analysis Proposed Rule TSD. Additionally, these emission reduction values vary slightly from the technology reduction estimates described in Section VI.C, as the values here reflect (1) the sum of the final identified stringency for each state (*e.g.,* SCR retrofit potential is not assumed in Alabama, Delaware, and Tennessee), and (2) generation shifting reduction potential identified at each step.

[c] The total and average ppb results from non-EGUs emissions reductions shown here were generated using the Step 3 AQAT methodology consistent with that for EGUs (*i.e.,* including reductions from the state containing the receptor and excluding states that are not explicitly linked to particular receptors). The values shown in Table VI.C.2–1 were prepared for the non-EGU screening assessment using a methodology where states within the program make emissions reductions for all receptors. States that contain receptors (*i.e.,* Connecticut and Colorado) that are not linked to other receptors are not assumed to make reductions under that methodology.

[d] The cumulative ppb change only shows the aggregate change across all problematic receptors (some of which are located within close proximity to one another) in this part of the Step 3 analysis. Section IX of this proposed rule provides a more complete picture of the air quality impacts of the proposed rule.

4. Over-Control Analysis

The EPA applied its over-control test to this same set of aggregated EGU and non-EGU data described in the previous section. As part of the air quality analysis using the Ozone AQAT, the EPA evaluated potential over-control with respect to whether (1) the expected ozone improvements would be greater than necessary to resolve the downwind ozone pollution problem (*i.e.,* beyond what is necessary to resolve all nonattainment and maintenance problems to which an upwind state is linked) or (2) the expected ozone improvements would reduce the upwind state's ozone contributions below the screening threshold (*i.e.,* 1 percent of the 2015 ozone NAAQS).

In *EME Homer City,* the Supreme Court held that the EPA cannot ''require[ ] an upwind State to reduce emissions by more than the amount necessary to achieve attainment in every downwind State to which it is linked.'' 572 U.S. at 521. On remand from the Supreme Court, the D.C. Circuit held that this means that the EPA might overstep its authority ''when those downwind locations would achieve attainment even if less stringent emissions limits were imposed on the upwind States linked to those locations.'' *EME Homer City II,* 795 F.3d at 127. The D.C. Circuit qualified this statement by noting that this ''does not mean that every such upwind state would then be entitled to less stringent emissions limits. Some of those upwind States may still be subject to the more stringent emissions limits so as not to cause other downwind locations to which those States are linked to fall into nonattainment.'' *Id.* at 14–15. As the Supreme Court explained, ''while EPA has a statutory duty to avoid over-control, the Agency also has a statutory obligation to avoid 'under-control,' *i.e.,* to maximize achievement of attainment downwind.'' 572 U.S. at 523. The Court noted that ''a degree of imprecision is inevitable in tackling the problem of interstate air pollution'' and that incidental over-control may be unavoidable. *Id.* ''Required to balance the possibilities of under-control and over-control, EPA must have leeway in fulfilling its statutory mandate.'' *Id.*[205]

Consistent with these instructions from the Supreme Court and the D.C. Circuit, using the Ozone AQAT, the EPA first evaluated whether reductions resulting from the selected control stringencies for EGUs in 2023 and 2026 combined with the emissions reductions selected for non-EGUs in 2026 can be anticipated to resolve any downwind nonattainment or maintenance problems (see the Ozone Policy Analysis Proposed Rule TSD for details on the construction and application of AQAT). The control stringency selected for 2023 (a representative cost threshold of $1,800 per ton for EGUs) includes emissions reductions commensurate with optimization of existing SCRs and SNCRs and installation of state-of-the-art combustion controls, which are estimated to change the status of one maintenance receptor, shifting the Clark County, Nevada monitor to attainment in 2023. However, no other nonattainment or maintenance problems would be resolved in 2023 with this level of stringency, and no state is linked solely to this receptor. Nor do any states' contribution levels drop below the 1% of NAAQS threshold. Thus, the EPA determined that none of the 26 linked states have all of their linkages resolved at the proposed EGU level of control stringency in 2023, and hence, the EPA finds no over-control in the proposed level of stringency.

Based on the air quality baseline modeling for 2026, all receptors to which Alabama, Delaware, and Tennessee are linked in 2023 are projected to be in attainment in 2026. Therefore, no additional emissions reductions are proposed for EGUs or non-EGUs in those states beyond the 2023 level of stringency. For the remaining 23 states, the selected control stringency (at a representative cost per ton threshold of $11,000 for EGUs and a marginal cost threshold of $7,500 for non-EGUs) beginning in 2026 includes additional EGU controls and estimated non-EGU emissions reductions for Tier 1 and Tier 2 non-EGU industries. The EPA used the Ozone AQAT to evaluate the impact of this selected stringency level (as well as other potential stringency levels) on all receptors remaining in the 2026 air quality modeling base case. This assessment shows that the selected control stringency level and emissions reductions are estimated to change the status of three maintenance receptors to attainment in 2026—Douglas County, Colorado; Brazoria County, Texas; and Kenosha County, Wisconsin. Based on these data, EPA proposes that at least 20 of the 23 states continue to be linked to nonattainment or maintenance receptors after implementation of all identified Step 3 reductions, and hence, the EPA finds no over-control in its determination of that level of stringency for those 20 states.

For 2 of the 23 states, Arkansas and Mississippi, the last downwind receptor to which these two states are linked (*i.e.,* Brazoria County, Texas) is estimated to achieve attainment and maintenance after full application of EGU reductions and Tier 1 non-EGU reductions. This suggests application of the estimated non-EGU emissions reductions from Tier 2 *may* constitute over-control for these states. However, this downwind

[205] Although the Court described over-control as going beyond what is needed to address ''nonattainment'' problems, the EPA interprets this holding as not impacting its approach to defining and addressing both nonattainment and maintenance receptors. In particular, the EPA continues to interpret the Good Neighbor provision as requiring it to give independent effect to the ''interfere with maintenance'' prong. *Accord Wisconsin,* 938 F.3d at 325–27.

receptor only resolves by a small margin after the application of all EGU and Tier 1 non-EGU emissions reductions. The EPA anticipates that updates to emissions inventories, emissions reduction potential from identified technologies, or the over-control test methodology resulting from comments or other updated information could possibly move this site back into nonattainment- or maintenance-receptor status when the EPA conducts an over-control analysis prior to finalizing this proposal.

For 1 of the 23 states, Wyoming, the EPA also notes a potential over-control finding under the methodological assumption where emissions reductions of commensurate stringency are assumed in the downwind state of Colorado (which is not subject to this proposal). As demonstrated in the Ozone Transport Policy Analysis Proposed Rule TSD, the last downwind receptor for Wyoming (*i.e.,* Douglas County, Colorado) is estimated to achieve attainment and maintenance after full application of EGU reductions. This suggests application of estimated non-EGU emissions reductions from Tier 1 and Tier 2 industries may constitute over-control for this state. However, when the assumption of commensurate downwind state reductions in Colorado is removed from the methodology, the downwind receptor to which Wyoming is linked does not resolve and there is no identified over-control estimated for Wyoming.[206]

Next, the EPA evaluated the potential for over-control with respect to the 1 percent of the NAAQS threshold applied in this proposed rulemaking at Step 3 of the good neighbor framework, assessed for the selected control stringencies for each state for each period that downwind nonattainment and maintenance problems persist (*i.e.,* 2023 and 2026). Specifically, the EPA evaluated whether the selected control stringencies would reduce upwind emissions to a level where the contribution from any of the 26 linked states in 2023 or 23 linked states in 2026 would be below the 1 percent threshold. The EPA finds that for the mitigation measures assumed in 2023 and in 2026, all states that contributed greater than or equal to the 1 percent threshold in the base case continued to contribute greater than or equal to 1 percent of the NAAQS to at least one remaining downwind nonattainment or maintenance receptor for as long as that receptor remained in nonattainment or maintenance. In the case of Arkansas, Mississippi, and Wyoming, while their linkages resolved based on a change in receptor status at Step 1 (as discussed above), their contribution to the relevant monitoring sites remained above 1 percent of the NAAQS, and thus, the potential basis for an over-control finding with respect to these states is not based on their contribution dropping below 1 percent of the NAAQS at those sites. For more information about this assessment, refer to the Ozone Transport Policy Analysis Proposed Rule TSD and the Ozone AQAT.

Based on these results, under no scenario does EPA's AQAT analysis for this proposal indicate that including all identified EGU reductions would constitute over-control. Rather, if these results hold for a final rule, the potential over-control for Arkansas and Mississippi can be avoided by not requiring Tier 2 non-EGU reductions, and over-control for Wyoming can be avoided by not requiring any non-EGU reductions.

Nonetheless, while acknowledging these preliminary analytic results, the EPA is proposing that all of the selected EGU and non-EGU NO_X reduction strategies selected in EPA's Step 3 analysis be applied to all linked states in 2026—including to Arkansas, Mississippi, and Wyoming—to eliminate significant contribution to nonattainment and interference with maintenance of the 2015 ozone NAAQS. The Supreme Court has directed the EPA to avoid both over-control and under-control in addressing good neighbor obligations. In addition, the D.C. Circuit has reinforced that over-control must be established based on particularized, record evidence on an as-applied basis. As noted previously, even slight changes in analytics based on comments or new information between proposal and final could result in the Brazoria, Texas site remaining either a nonattainment or maintenance receptor. Further, with respect to Wyoming, its linkage only resolves based on an unenforceable assumption regarding a certain level of emissions reduction in Colorado. The proposed determination that the stringency of this proposal does not constitute over-control for any linked state is further reinforced by EPA's observation in Section IV.A.1 of this proposed rule regarding the nature of ozone, and in particular, that future ozone concentrations and the formation of ground level ozone, may be impacted by climate change in future years.

Under these circumstances, the EPA cannot conclude based on the current record that any aspect of its selected Step 3 level of control stringency constitutes unnecessary over-control for any of the 23 states found to be linked in 2026. The EPA requests comment on this proposed conclusion. The EPA requests comment on an alternative conclusion that, if this same analysis were to persist for a final rule, it must limit non-EGU reduction requirements for Arkansas and Mississippi to only the Tier 1 industries, and for Wyoming to limit the stringency of the rule to only the EGU reduction strategies.

VII. Implementation of Emissions Reductions

A. NO_X Reduction Implementation Schedule

This proposal, if finalized, will ensure that emissions reductions necessary to eliminate significant contribution will be achieved as ''as expeditiously as practicable'' as required under CAA section 181(a). The EPA's anticipated timing will provide for all possible emissions reductions to go into effect beginning in the 2023 ozone season, which is aligned with the next upcoming attainment date of August 3, 2024, for areas classified as Moderate nonattainment under the 2015 ozone standard. Additional emissions reductions that the EPA finds not possible to implement by that attainment date are proposed to take effect as expeditiously as practicable, with the full suite of emissions reductions taking effect by the 2026 ozone season, which is aligned with the August 3, 2027, attainment date for areas classified as Serious nonattainment under the 2015 ozone NAAQS. This schedule of emissions reductions meets the requirement in the Good Neighbor Provision that it must be

[206] In this proposal, the EPA continues to assume, as it has in prior transport rules, that home-states (that are not otherwise linked) will make similar reductions as those assumed in this action for purposes of local attainment. While the EPA continues to view this to be an equitable means of assessing air quality improvement from good neighbor actions, because the downwind receptor state is assumed to do its ''fair share,'' the EPA recognizes that recent case law has called the need for such an assumption into question, and thus using this assumption as a basis for finding over-control may be inappropriate. In *Maryland,* the EPA had argued that good neighbor obligations should not be required by the Marginal area attainment deadline in part because ''marginal nonattainment areas often achieve the NAAQS without further downwind reductions, so it would be unreasonable to impose reductions on upwind sources based on the next marginal attainment deadline.'' 958 F.3d 1185, 1204. The D.C. Circuit rejected that argument, noting regulatory consequences for the downwind state for failure to attain even at the Marginal date, and, citing *Wisconsin,* the court held that upwind sources violate the good neighbor provision if they significantly contribute even at the Marginal area attainment date. *Id.* Thus, the EPA examines over-control in this proposal with and without this assumption of home-state emission reductions.

implemented ''consistent with the provisions of [title I of the CAA.]'' CAA section 110(a)(2)(D)(i). Finally, the timing of this proposed rulemaking is designed to achieve reductions as expeditiously as practicable while adhering to the procedural requirements of CAA section 110. The EPA proposes this rule to constitute a full remedy for interstate transport for the 2015 ozone NAAQS for the states covered by this proposal; the EPA does not anticipate further rulemaking to address good neighbor obligations will be required for these states with the finalization of this rule.

EPA's proposed determinations regarding the timing of this proposed rule are informed by and in compliance with several recent court decisions. The D.C. Circuit has reiterated several times since 2008 that, under the terms of the Good Neighbor Provision, upwind states must eliminate their significant contributions to downwind areas ''consistent with the provisions of [title I of the Act],'' including those provisions setting attainment deadlines for downwind areas.[207] In *North Carolina,* the D.C. Circuit found the 2015 compliance deadline that the EPA had established in CAIR unlawful in light of the downwind nonattainment areas' 2010 deadline for attaining the 1997 NAAQS for ozone and $PM_{2.5}$.[208] Similarly, in *Wisconsin,* the Court found the CSAPR Update unlawful to the extent it allowed upwind states to continue their significant contributions to downwind air quality problems beyond the downwind states' statutory deadlines for attaining the 2008 ozone NAAQS.[209] More recently, in *Maryland,* the Court found the EPA's selection of a 2023 analysis year in evaluating state petitions submitted under CAA section 126 unlawful in light of the downwind Marginal nonattainment areas' 2021 deadline for attaining the 2015 ozone NAAQS.[210] The Court noted in *Wisconsin* that the statutory command—that compliance with the Good Neighbor Provision must be achieved in a manner ''consistent with'' title I of the CAA—may be read to allow for some deviation from the mandate to eliminate prohibited transport by downwind attainment deadlines, ''under particular circumstances and upon a sufficient showing of necessity,'' but concluded that ''[a]ny such deviation would need to be rooted in Title I's framework'' and would need to ''provide a sufficient level of protection to downwind States.''[211]

1. 2023–2025: EGU NO_X Reductions Beginning in 2023

The near-term EGU control stringencies and corresponding reductions in this proposed rulemaking cover the 2023, 2024, and 2025 ozone seasons. This is the period in which some reductions will be available, but the large portion of full remedy reductions—mainly those reductions that are driven by post combustion control installation—identified in Sections VI.B through VI.D of this proposed rule are not yet available. The EGU NO_X mitigation strategies available during these initial 3 years are the optimization of existing post-combustion controls (SCRs and SNCRs) and combustion control upgrades. As described in Sections VI.B through VI.D of this proposed rule and in accompanying TSDs, these mitigation measures can be implemented in under two months in the case of existing control optimization and in 6 months in the case of combustion control upgrades.

As described in Section VI.B of this proposed rule and in the identified TSDs, these timing assumptions account for planning, procurement, and any physical or structural modification necessary. The EPA provides significant historical data, including the implementation of the most recent Revised CSAPR Update, as well as engineering studies and input factor analysis documenting the feasibility of these timing assumptions. However, these timing assumptions are representative of fleet averages, and the EPA has noted that some units will likely overperform their installation timing assumptions, while others may have unit configuration or operational considerations that result in their underperforming these timing assumptions. As in prior interstate transport rules, the EPA is implementing these EGU reductions through a trading program approach. The trading program's option to buy additional allowances provides flexibility in the program for outlier sources that may need more time than what is representative of the fleet average to implement these mitigation strategies while providing an economic incentive to outperform rate and timing assumptions for those sources that can do so. In effect, this trading program implementation operationalizes the mitigation measures as state-wide assumptions for the EGU fleet rather than unit-specific assumptions.

However, starting in 2024, as described in Section VII.B.7 of this proposed rule, unit-specific daily emissions rate limits are applied to coal units with existing SCR at a level consistent with operating that control. The EPA believes that implementing these emissions reductions at the state level starting in 2023 (through state emissions budgets) while imposing the unit-specific emissions rate limits in 2024 achieves the necessary environmental performance as soon as possible while accommodating any heterogeneity in unit-level implementation schedules regarding daily operation of optimized SCRs.

Additionally, as in prior rules, the EPA assumes combustion control upgrade implementation may take up to 6 months. In the Revised CSAPR Update, covering 12 of the 25 states for which emissions reduction requirements for EGUs are established under this proposed action, the EPA finalized the rule in March of 2021 and thus did not require these combustion control-based emissions reductions in ozone-season state emissions budgets until 2022 (year two of that program).[212] The EPA is applying the same timing assumption regarding combustion control upgrades for this proposed rulemaking given the expected similar window between an anticipated final action date and the start of the year one ozone season. The EPA is not assuming the implementation of any additional combustion control upgrades in state emissions budgets until 2024. Therefore, those 13 states covered in this action for EGU emissions reductions that were not covered in the Revised CSAPR Rule have 2023 emissions budgets that only reflect optimization of existing controls. Any identified combustion control upgrade emissions reductions are reflected beginning in the 2024 ozone-season budgets for these states. For the 12 states covered under the Revised CSAPR Update, any identified emissions reduction potential from combustion control upgrade was included and reflected in those state budgets beginning in 2022 under the Revised CSAPR Update. Therefore, the

[207] *North Carolina* v. *EPA,* 531 F.3d 896 (D.C. Cir. 2008), *Wisconsin* v. *EPA,* 938 F.3d 303 (D.C. Cir. 2019), and *Maryland* v. *EPA,* 958 F.3d 1185 (D.C. Cir. 2020).

[208] *North Carolina,* 531 F.3d at 911–913.

[209] *Wisconsin,* 938 F. 3d at 303, 3018–20.

[210] *Maryland,* 958 F.3d at 1203–1204. Similarly, in *New York* v. *EPA,* 964 F.3d 1214 (D.C. Cir. 2020), the Court found the EPA's selection of a 2023 analysis year in evaluating New York's section 126 petition unlawful in light of the New York Metropolitan Area's 2021 Serious area deadline for attaining the 2008 ozone NAAQS. 964 F.3d at 1226 (citing *Wisconsin* and *Maryland*).

[211] *Wisconsin,* 938 F. 3d at 320 (citing CAA section 181(a) (allowing one-year extension of attainment deadlines in particular circumstances) and *North Carolina,* 531 F.3d at 912).

[212] 86 FR 23093.

EPA is assuming that this combustion control upgrade potential is available, if not already realized, by the first year of this action (*i.e.,* 2023) in this proposed rule.

2. 2026 and Later Years: EGU and Non-EGU NO_X Reductions Beginning in 2026

In accordance with the good neighbor provision and the downwind attainment schedule under CAA section 181 for the 2015 ozone NAAQS, the EPA is proposing to align its analysis and implementation of the emissions reductions addressing significant contribution from EGU and non-EGU sources that require relatively longer lead time at a sectoral scale with the 2026 ozone season, which is the last full ozone season preceding the August 3, 2027, Serious area attainment date for the 2015 ozone NAAQS.[213] The EPA proposes to find that this compliance deadline is the most expeditious date practicable and would achieve the required emissions reductions prior to the next applicable attainment date by which such reductions are, in fact, possible. The EPA proposes to find that it is not possible to require implementation of all necessary emissions controls across all of the affected EGU and non-EGU sources by the August 3, 2024, Moderate area attainment date.

Thus, the EPA is proposing to require compliance with the control requirements for all non-EGUs and the EGU reductions related to post-combustion control retrofit identified in this section no later than the 2026 ozone season (May through September). If finalized in early 2023, the final rule would provide more than three years for EGU and non-EGU sources to install whatever controls they deem suitable to comply with required emissions reductions by the 2026 ozone season. In addition, the publication of this proposal provides roughly an additional year of notice to these source owners and operators that they should begin engineering and financial planning now to be prepared to meet this implementation timetable.

The EPA views this timeframe for retrofitting post-combustion NO_X emissions controls and other non-EGU controls to be presumptively reasonable and achievable. A 3-year period for installation of post-combustion control technologies is consistent with the statutory timeframe for implementation of the controls required to address interstate pollution under section 110(a)(2)(D) and 126 of the Act, the statutory timeframes for implementation of RACT in ozone nonattainment areas classified as Moderate or above, and other statutory provisions that establish control requirements for existing stationary sources of pollution.

For example, section 126 of the CAA authorizes a downwind state or tribe to petition the EPA for a finding that emissions from ''any major source or group of stationary sources'' in an upwind state contribute significantly to nonattainment in, or interfere with maintenance by, the downwind state. If the EPA makes a finding that a major source or a group of stationary sources emits or would emit pollutants in violation of the relevant prohibition in CAA section 110(a)(2)(D), the source(s) must shut down within 3 months from the finding unless the EPA directly regulates the source(s) by establishing emissions limitations and a compliance schedule extending no later than three years from the date of the finding, to eliminate the prohibited interstate transport of pollutants as expeditiously as practicable.[214] Thus, in the provision that allows for direct federal regulation of sources violating the good neighbor provision, Congress established 3 years as the maximum amount of time available from a final action to when emissions reductions need to be achieved at the relevant source or group of sources.

Additionally, for ozone nonattainment areas classified as Moderate or higher, the CAA requires states to implement RACT requirements less than three years after the statutory deadline for submitting these measures to the EPA.[215] Specifically, for these areas, CAA sections 182(b)(2) and 182(f) require that states implement RACT for existing VOC and NO_X sources as expeditiously as practicable but no later than May 31, 1995, approximately 30 months after the November 15, 1992, deadline for submitting RACT SIP revisions. For purposes of the 2015 ozone NAAQS, the EPA has interpreted these provisions to require implementation of RACT SIP revisions as expeditiously as practicable but no later than January 1 of the fifth year after the effective date of designation, which is less than 3 years after the deadline for submitting RACT SIP revisions.[216] For areas initially designated nonattainment with a Moderate or higher classification effective August 3, 2018 (83 FR 25776), that implementation deadline falls on January 1, 2023, approximately 29 months after the August 3, 2020 submission deadline.[217] Moderate ozone nonattainment areas must also implement all reasonably available control measures (including RACT) needed for expeditious attainment within three years after the statutory deadline for states to submit these measures to the EPA as part of a Moderate area attainment demonstration.[218]

The EPA notes that the types and sizes of the EGU and non-EGU sources that the EPA proposes to include in this proposed rule, as well as the types of emissions control technologies on which the EPA proposes to base the

[213] For each nonattainment area classified under CAA section 181(a) for the 2015 ozone NAAQS, the attainment date is ''as expeditiously as practicable'' but not later than the date provided in table 1 to 40 CFR 51.1303(a). Thus, for areas initially designated nonattainment effective August 3, 2018 (83 FR 25776), the latest permissible attainment dates are: August 3, 2021 (for Marginal areas), August 3, 2024 (for Moderate areas), August 3, 2027 (for Serious areas), and August 3, 2033 (for Severe areas).

[214] CAA 110(a)(2)(D)(i) and 126(c).

[215] *See, e.g.,* 40 CFR 51.1112(a)(3) and 51.1312(a)(3)(i) (requiring implementation of RACT required pursuant to initial nonattainment area designations no later than January 1 of the fifth year after the effective date of designation, which is less than 3 years after the submission deadline under 40 CFR 51.1112(a)(2)) and 51.1312(a)(2)(i), respectively).

[216] 40 CFR 51.1312(a)(2)(i) (requiring submission of RACT SIP revisions no later than 24 months after the effective date of designation) and 51.1312(a)(3)(i) (requiring implementation of RACT SIP revisions as expeditiously as practicable, but no later than January 1 of the fifth year after the effective date of designation). For reclassified areas, states must implement RACT SIP revisions as expeditiously as practicable, but no later than the start of the attainment year ozone season associated with the area's new attainment deadline, or January 1 of the third year after the associated SIP revision submittal deadline, whichever is earlier; or the deadline established by the Administrator in the final action issuing the area reclassification. 40 CFR 51.1312(a)(3)(ii); *see* also 83 FR 62989, 63012–63014.

[217] 40 CFR 51.1312(a)(2)(i) (requiring submission of RACT SIP revisions no later than 24 months after the effective date of designation).

[218] *See, e.g.,* 40 CFR 51.1108(d) (requiring implementation of all control measures (including RACT) needed for expeditious attainment no later than the beginning of the attainment year ozone season, which, for a Moderate nonattainment area, occurs less than 3 years after the deadline for submission of reasonably available control measures under 40 CFR 51.1112(c) and 51.1108(a)) and 40 CFR 51.1308(d) (requiring implementation of all control measures (including RACT) needed for expeditious attainment no later than the beginning of the attainment year ozone season, which, for a Moderate nonattainment area, occurs less than three years after the deadline for submission of reasonably available control measures under 40 CFR 51.1312(c) and 51.1308(a)). Because the attainment demonstration for a Moderate nonattainment area (including RACT needed for expeditious attainment) is due three years after the effective date of the area's designation (40 CFR 51.1308(a) and 51.1312(c)), and all Moderate nonattainment areas must attain the NAAQS as expeditiously as practicable but no later than 6 years after the effective date of the area's designation (40 CFR 51.1303(a)), the beginning of the ''attainment year ozone season'' (as defined in 40 CFR 51.1300(g)) for such an area is less than three years after the due date for the attainment demonstration.

emissions limitations that would take effect for the 2026 ozone season, generally are intended to be consistent with the scope and stringency of RACT requirements for existing major sources of NO_X in downwind Moderate nonattainment areas and some upwind areas, which many states have already implemented in their SIPs.[219] Thus, the timing Congress allotted for sources in downwind states to come into compliance with RACT requirements bears directly on the amount of time that should be allotted here and indicates, as does CAA section 126, that 3 years is an outer limit on the time that should be given sources to come into compliance.

Finally, with respect to emissions standards for hazardous air pollutants, section 112(i)(3) of the CAA requires the EPA to establish compliance dates for each category or subcategory of existing sources subject to an emissions standard that ''provide for compliance as expeditiously as practicable, but in no event later than 3 years after the effective date of such standard,'' with limited exceptions.[220] Here again, where Congress was concerned with addressing emissions of pollutants that impact public health, a 3-year time period was allotted as the time needed for existing sources to come into compliance.

All of these statutory timeframes for implementation of new control requirements on existing stationary sources indicate that Congress considered 3 years to be not only a sufficient amount of time but a maximum amount of time allowable for existing stationary sources to install pollution controls as necessary for expeditious attainment, to eliminate prohibited interstate transport of pollutants, and to protect public health.

Further, the EPA notes that, given the number of years that have passed since EPA's promulgation of the 2015 ozone NAAQS and related nonattainment area designations in 2018, and in light of the *Maryland* court's holding that good neighbor obligations for the 2015 ozone NAAQS should have been implemented by the Marginal area attainment date in 2021,[221] many states are substantially delayed in implementing their good neighbor obligations for these NAAQS, and the sources proposed for NO_X emissions control in this rule have continued to operate for several years without the controls necessary to eliminate their significant contribution to ongoing and persistent ozone nonattainment and maintenance problems in other states. Under these circumstances, we find it more than reasonable to require compliance with the control requirements for all non-EGUs and the EGU reductions related to post-combustion control retrofit identified in Section VI.B.1.b of this proposed rule by the beginning of the 2026 ozone season (*i.e.,* by May 1, 2026). May 1, 2026, is more than 3 years after the date by which the EPA currently anticipates promulgating a final FIP for the covered states, more than three years after the January 1, 2023, deadline for implementation of section 182 RACT SIP provisions in areas classified as Moderate or higher, and almost 8 years after the October 1, 2018, deadline for submission of good neighbor SIPs that prohibit significant contribution to nonattainment or interference with maintenance in downwind states.[222]

As the D.C. Circuit noted in *Wisconsin,* the good neighbor provision requires upwind states to ''eliminate their substantial contributions to downwind nonattainment in concert with the attainment deadlines'' in the downwind states, even where those attainment deadlines occur before EPA's statutory deadline to promulgate a FIP.[223] Referencing the Supreme Court's description of the attainment deadlines as ''the heart'' of the CAA, the *Wisconsin* court noted that some deviation from the mandate to eliminate prohibited transport by downwind attainment deadlines may be allowed only ''under particular circumstances and upon a sufficient showing of necessity,'' *e.g.,* when compliance with the statutory mandate amounts to an impossibility.[224]

For the reasons provided below in this section, the EPA is proposing to find that installation of certain EGU controls and all non-EGU controls is not possible by the Moderate area attainment date for the 2015 ozone NAAQS (*i.e.,* August 3, 2024),[225] and that the 2026 ozone season, which corresponds to the August 3, 2027, Serious area attainment date for these NAAQS, is the earliest downwind attainment date by which the required emissions reductions from these strategies are possible.

a. EGU Schedule for 2026 and Later Years

As discussed in Sections VI.B through VI.D of this proposed rule, significant emissions reduction potential exists and is included in EPA's quantification of significant contribution based on the potential to install post-combustion controls (SCR and SNCRs) at EGUs. However, as discussed in detail in those sections, the assumption for installation of this technology on a region-wide scale is 36 months in this proposed rule. This amount of time allows for all necessary procurement, permitting, and installation milestones across multiple units in the covered region. Therefore, the EPA proposes to find that these emissions reductions are not available any earlier than the 2026 compliance period. For each year in 2026 and beyond, state emissions budgets include reductions commensurate with these post-combustion control technologies identified for covered units in Step 3. The EPA notes that similar compliance schedules and post-combustion control retrofit installations have been realized successfully in prior programs allowing similar timeframes. Subsequent to the NO_X SIP Call and the parallel Finding of Significant Contribution and Rulemaking on Section 126 Petitions (which became effective December 28, 1998, and February 17, 2000, respectively [226]), nearly 19 GW of SCR

[219] *See* the Non-EGU Sectors TSD for a discussion of SIP-approved RACT rules in effect in downwind states.

[220] CAA section 112(i)(3)(B) generally authorizes the EPA to grant an extension of up to 1 additional year for an existing source to comply with emissions standards ''if such additional period is necessary for the installation of controls,'' and sections 112(i)(4) through (8) provide for limited extensions granted by the President where certain conditions are met, for existing sources that have installed the best available control technology (BACT) or technology required to meet a lowest achievable emissions rate (LAER), and for new sources for which construction or reconstruction is commenced by certain dates.

[221] 958 F.3d at 1203–1204 (remanding the EPA denial of section 126 petition based on the EPA analysis of downwind air quality in 2023 rather than 2021, the year containing the Marginal area attainment date).

[222] CAA sections 110(a)(1) and 110(a)(2)(D)(i) (requiring states to submit, within 3 years after EPA's promulgation of a new or revised NAAQS, SIP provisions adequate to satisfy the Good Neighbor Provision). As the Supreme Court noted in *EME Homer City I,* ''nothing in the statute places EPA under an obligation to provide specific metrics to States before they undertake to fulfill their good neighbor obligations.'' 572 U.S. 489, 510.

[223] 938 F.3d at 317–318. For example, the court observed that the EPA may shorten the deadline for SIP submissions under CAA section 110(a)(1) and may issue FIPs soon thereafter under CAA section 110(c)(1), to align the upwind states' deadline for satisfying good neighbor obligations with the downwind states' deadline for attaining the NAAQS. *Id.* at 318.

[224] *Id.* at 316 and 319–320 (noting that any such deviation must be ''rooted in Title I's framework'' and ''provide a sufficient level of protection to downwind States'').

[225] Compliance by the August 3, 2021, Marginal area attainment date is also impossible as that date has passed.

[226] *See* 63 FR 57356 (October 27, 1998); 65 FR 2674 (January 18, 2000). The D.C. Circuit stayed the NO_X SIP Call by an order issued May 25, 1999. After upholding the rule in most respects in *Michigan* v. *EPA,* 213 F.3d 663 (D.C. Cir. 2000), the court lifted the stay by an order issued June 22, 2000.

retrofit came online in 2002 and another 42 GW of SCR retrofit came online for steam boilers in 2003, illustrating that a considerable volume of SCR retrofit capacity is possible in a 36 month period.

However, the EPA is not proposing to apply daily emissions rates on coal-fired steam EGUs assumed to retrofit SCR until 2027 (as described in Section VII.B.1.c.i of this proposed rule). The EPA believes that implementing these emissions reductions at the state level starting in 2026 (through state emissions budgets) while imposing the unit-specific emissions rate limits in 2027 achieves the necessary environmental performance as soon as possible while accommodating any heterogeneity in unit-level implementation schedules regarding installation of new SCR.[227]

b. Non-EGU Schedule for 2026 and Later Years

For the suite of non-EGU controls on which the EPA has based its Step 3 findings as described in Section VI of this proposed rule, the EPA proposes to require that these controls be installed and operational by the 2026 ozone season and to find that any earlier date is not possible. The EPA previously examined the time necessary to install the controls identified for several non-EGU industries. Although the information on installation times for most NO_X controls applied to glass and cement manufacturing was uncertain, the EPA identified minimum estimated installation times for a number of other non-EGU source categories that ranged from several weeks to slightly over a year. This included timeframes of 42–51 weeks for SNCR applied to dry cement manufacturing facilities and cement kilns/dryers burning bituminous coal, 28–58 weeks for SCR applied to boilers and process heaters, 28–58 weeks for SCR applied to iron and steel in-process combustion, and 6–8 months for low NO_X burners and flue gas recirculation at iron and steel mills.[228] Taking into account necessary scale-up of construction services for multiple control installations at several emissions units, the time needed to have NO_X monitoring installed and operating, and other necessary steps in the permitting and construction processes (*e.g.,* review of vendor bids), the EPA estimates an additional period of 6 to 18 months may be necessary for existing non-EGU sources to install the necessary controls, depending on the number of control installations at a facility.[229]

Additionally, the EPA previously considered the installation timing needs for NO_X controls (including SCR, SNCR, and combustion controls) at both EGU and non-EGU sources as part of the 1998 NO_X SIP Call.[230] With respect to combustion controls (*e.g.,* low-NO_X burners, overfire air, etc.), the EPA found that sources should be able to complete control technology installations and obtain relevant permits in relatively short timeframes given considerable experience at that time among sources and permitting agencies with the implementation of such controls, the fact that combustion controls are constructed of commonly available materials (steel, piping, etc.) and do not require reagent during operation, and the then availability of many vendors of combustion control technology.[231]

With respect to post-combustion controls (primarily SCR and SNCR), the EPA considered three basic factors in assessing installation timing needs: (1) Availability of materials and labor, (2) the time needed to implement controls at plants with single or multiple retrofit requirements, and (3) the potential for interruptions in power supply resulting from outages needed to complete installations on EGUs.[232] Assuming adequate supplies of both off-the-shelf hardware (such as steel, piping, nozzles, pumps, and related equipment) and the catalyst used in the SCR process, as well as sufficient vendor capacity to supply retrofit SCR catalyst to sources, and taking into account the additional time needed for facility engineering review, developing control technology specifications, awarding a procurement contract, obtaining a construction permit, completing control technology design, installation, and testing, and obtaining an operating permit, the EPA found that (a) about 21 months would be needed to implement an SCR retrofit on a single unit and (b) about 19 months would be needed to implement an SNCR retrofit on a single unit.[233] The EPA also examined several particularly complicated implementation efforts and found that 34 months would be needed for a plant to install a maximum of 6 SCRs while 24 months would be needed for a plant to install a maximum of 10 SNCRs.[234] Finally, the EPA found that the necessary controls could be installed on EGUs without any disruptions in the supply of electricity because connections between a NO_X control system and a boiler can generally be completed in 5 weeks or less and thus could occur during the 5-week planned outage that each EGU typically has each year.[235]

Thus, for both EGUs and non-EGUs, EPA's technical analysis for the 1998 NO_X SIP Call indicated that a 3-year period would be sufficient for installation of both combustion and post-combustion controls, from the planning and specification of controls to completion of control technology implementation.[236] EPA's evaluation of the timeframes for post-combustion controls was based on the Agency's projection that 639 retrofit installations at EGU sources and 235 retrofit installations at non-EGU industrial sources would be necessary for existing sources in the covered states to comply with the NO_X SIP Call.[237] Although the scope of types of non-EGU sources covered by this proposed FIP is broader, and the estimated number of emissions units is greater (potentially including as many as 490 emissions units), than the scope and number of non-EGU sources evaluated in the 1998 NO_X SIP Call, and although a later analysis of timeframes for installation of post-combustion controls at EGUs produced a more refined estimate for that sector only,[238] EPA's prior analyses nonetheless inform the evaluation in this proposal of the necessary implementation schedule for non-EGU sources given they generally address NO_X control technologies similar to those that the EPA anticipates non-EGU sources may install to comply with the provisions of the proposed FIP

[227] However, as discussed in Section VII.B.1.c.i of this proposed rule, EPA's determinations in this regard are *not* based on a finding that the retrofit of post-combustion controls would not be feasible in the 2026 ozone season for all relevant units. The EPA finds that such retrofits are available and feasible on a fleetwide scale starting in the 2026 ozone season.

[228] Final Technical Support Document (TSD) for the Final Cross-State Air Pollution Rule for the 2008 Ozone NAAQS, Assessment of Non-EGU NO_X Emissions Controls, Cost of Controls, and Time for Compliance Final TSD (''CSAPR Update Non-EGU TSD''), August 2016 (Table 3), available at *https://www.epa.gov/csapr/assessment-non-egu-NOx-emission-controls-cost-controls-and-time-compliance-final-tsd.* See also Institute of Clean Air Companies, SNCR Committee, ''White Paper, Selective Non-Catalytic Reduction (SNCR) For Controlling NO_X Emissions,'' at 5 (noting that ''SNCR retrofits typically do not require extended source shutdowns'').

[229] 63 FR 57356, 57448 (October 27, 1998). EPA generally anticipates that any required permitting processes may run concurrent with other steps in the installation processes and thus may not significantly lengthen the total time needed for installation.

(*e.g.,* SCR, SNCR, low-NO_X burners and ultra-low NO_X burners).

Additionally, as part of EPA's evaluation of installation timing needs in the proposed CAIR (69 FR 4566), the EPA projected that it would take on average 21 months to install an SCR on one EGU unit, 27 months to install a scrubber on one EGU unit, and 3 years to install seven SCRs at a single EGU.[239] The EPA also noted that some EGUs could install SCR controls in as short of a period as 13 months.[240] This information and EPA's general experience indicate that a two-year installation timeframe for a rule requiring installation of new control technologies across a variety of emissions sources in several industries on a regional basis is a relatively fast installation timeframe, but that a 3-year installation timeframe should be feasible for most if not all of the identified industries. A shorter installation timeframe of approximately one year would likely raise significant challenges for sources, suppliers, contractors, and other economic actors, potentially including customers relying on the products or services supplied by the regulated sources. Thus, if the EPA finalizes this proposed rule in 2023, implementation of the necessary emissions controls across all of the affected non-EGU sources by the August 3, 2024, Moderate area attainment date would not be possible.

For purposes of this proposed rule, the EPA estimates that the required controls for non-EGU source categories would take up to 3 years to install across the affected industries in the 23 states that remain linked in 2026. Therefore, based on the available information, the EPA proposes to require compliance with these non-EGU control requirements by the beginning of the 2026 ozone season.

The EPA requests comment on the time needed to install the various control technologies across all of the emissions units in the Tier 1 and Tier 2 industries. In particular, the EPA solicits comment on the time needed to obtain permits (including the potential applicability of NSR requirements), the availability of vendors and materials, design, construction, and the earliest possible installation times for SCR on glass furnaces; SNCR or SCR on cement kilns; ultra-low NO_X burners, low NO_X burners, and SCR on ICI boilers (coal-fired, gas-fired, or oil-fired); low NO_X burners on large non-EGU ICI boilers; and low emissions combustion, layered emissions combustion, NSCR, and SCR on reciprocating rich-burn or lean-burn IC engines.

With respect to emissions monitoring requirements, EPA requests comment on the costs of installing and operating CEMS at non-EGU sources without NO_X emissions monitors; the time needed to program and install CEMS at non-EGU sources; whether monitoring techniques other than CEMS, such as predictive emissions monitoring systems (PEMS), may be sufficient for certain non-EGU facilities, and the types of non-EGU facilities for which such PEMS may be sufficient; and the costs of installing and operating monitoring techniques other than CEMS.

The EPA also requests comment on whether the FIP should provide a limited amount of time beyond the 2026 ozone season for individual non-EGU sources to meet the emissions limitations and associated compliance requirements, based on a facility-specific demonstration of necessity. As the D.C. Circuit stated in *Wisconsin,* the good neighbor provision may be read to allow for some deviation from the mandate to eliminate prohibited transport by downwind attainment deadlines, ''under particular circumstances and upon a sufficient showing of necessity,'' provided such deviation is ''rooted in Title I's framework [and] provide[s] a sufficient level of protection to downwind States.'' [241] Consistent with this directive, and recognizing that in general, the EPA aligns good neighbor obligations in the first instance with the last full ozone season before the downwind attainment date, the EPA requests comment on whether individual non-EGU sources should be allowed to request an extension of the May 1, 2026, compliance deadline by no more than 1 year (*i.e.,* to May 1, 2027) based on a sufficient showing of necessity. Any such comments should be supported by a detailed discussion of the facility-specific economic, technological, and other circumstances that may justify such an extension. The EPA notes that claims about infeasibility of controls are generally insufficient to justify an extension of time to comply, given the *Wisconsin* court's holding that the good neighbor provision requires upwind states to eliminate their significant contribution in accordance with the downwind states' attainment deadlines, without regard to questions of feasibility.[242]

The EPA solicits comment on the specific criteria that the EPA should apply in evaluating requests for extension of the 2026 compliance deadline for non-EGU sources. Such criteria could include documentation of inability, despite best efforts, to procure necessary materials or equipment (*e.g.,* equipment manufacturers are not able to deliver equipment before a specific date) or hire labor as needed to install the emissions control technology by 2026; documentation of installation costs well in excess of the highest representative cost-per ton threshold identified for any source (including EGUs) discussed in Section VI of this proposed rule (*e.g.,* vendor estimate showing equipment cost); documentation of a source owner or operator's inability to secure necessary financing, due to circumstances beyond the owner/operator's control, in time to complete the installation of controls by 2026; or documentation of extreme financial or technological constraints that would require the subject non-EGU emissions unit or facility to significantly curtail its operations or shut down before it could comply with the requirements of this proposed rule by 2026. Finally, the EPA requests comment on the process through which the EPA should review and act on an extension request—*e.g.,* the appropriate deadline for submitting a request, and whether the EPA should provide an opportunity for public comment before granting or denying a request.

The EPA anticipates that the owner or operator of the facility would bear the burden of establishing the necessity of an extension of time to comply, based on particular circumstances described and sufficiently documented in the submitted request. Claims of generalized financial or economic hardship or any claim that controls are not necessary to eliminate significant contribution would

[240] Final Report, ''Engineering and Economic Factors Affecting the Installation of Control Technologies for Multipollutant Strategies,'' EPA–600/R–02/073 (October 2002), at 21.

[241] *Wisconsin,* 938 F. 3d at 320 (citing CAA section 181(a) (allowing one-year extension of attainment deadlines in particular circumstances) and *North Carolina,* 531 F.3d at 912).

[242] *Wisconsin,* 938 F.3d at 313–314, 319 (''When an agency faces a statutory mandate, a decision to disregard it cannot be grounded in mere infeasibility''). We note also that in the CSAPR Close-Out Rule (83 FR 65878, December 21, 2018), the EPA required no further reductions from upwind states beyond those set forth in the prior CSAPR Update based, in part, on the Agency's conclusion that it was not feasible to implement cost-effective emissions controls before 2023, 2 years after the 2021 attainment deadline for the downwind serious areas. The D.C. Circuit vacated the Close-Out Rule for its reliance on the same interpretation of the Good Neighbor Provision that the court had rejected in *Wisconsin. New York* v. *EPA,* 781 F. App'x 4 (D.C. Cir. 2019) (unpublished opinion).

not suffice to justify an extension. If the EPA finalizes a provision allowing sources to request limited extensions of time to comply, the Agency would review each request on a case-by-case basis as necessary to ensure consistency with the provisions of title I of the CAA.

B. Regulatory Requirements for EGUs

To implement the required emissions reductions from EGUs, the EPA proposes to revise the existing CSAPR NO_X Ozone Season Group 3 Trading Program (the ''Group 3 trading program'') established in the Revised CSAPR Update both to expand the program's geographic scope and to enhance the program's ability to ensure favorable environmental outcomes.[243] The EPA proposes to use a trading program for EGUs because of the inherently greater flexibility that a trading program can provide relative to more prescriptive, ''command-and-control'' forms of regulation of sufficient stringency to achieve the necessary emissions reductions. In the electric power sector, EGUs' extensive interconnectedness and coordination create the ability to shift both electricity production and emissions among units, providing a closely related ability to achieve emissions reductions in part by shifting electricity production from higher-emitting units to lower-emitting or non-emitting units. The sector's unusual flexibility with respect to how emissions reductions can be achieved makes the flexibility of a trading program particularly useful as a means of lowering the overall costs of obtaining such reductions. In addition, it is essential for the electric power sector to retain short-term operational flexibility sufficient to allow electricity to be produced at all times in the quantities needed to meet demand simultaneously, and the flexibility of a trading program can be helpful in supporting this aspect of the industry as well. As discussed later, to provide improved environmental outcomes, in this rulemaking, the EPA is proposing certain enhancements to the current provisions of the Group 3 trading program addressing environmental performance that will necessarily reduce the flexibility of the individual units participating in the program to some extent. However, with the proposed enhancements, the EPA believes the inherently greater flexibility of a trading program continues to favor the use of this form of regulation, relative to more prescriptive forms of regulation, as a vehicle for achieving the emissions reductions from the electric power sector found to be necessary in this rulemaking.

The Group 3 trading program currently applies to EGUs meeting the program's applicability criteria within the borders of twelve states: Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, New Jersey, New York, Ohio, Pennsylvania, Virginia, and West Virginia. Affected EGUs in these twelve states would continue to participate in the Group 3 trading program as revised in this rulemaking, with some revised provisions taking effect in the 2023 control period and other revised provisions taking effect later as discussed elsewhere in this document. The EPA proposes to expand the Group 3 trading program's geographic scope to include all of the additional states for which EGU emissions reduction requirements are being established in this rulemaking. Affected EGUs within the borders of eight states currently covered by the CSAPR NO_X Ozone Season Group 2 Trading Program (the ''Group 2 trading program'')—Alabama, Arkansas, Mississippi, Missouri, Oklahoma, Tennessee, Texas, and Wisconsin—would transition from the Group 2 program to the revised Group 3 trading program at the beginning of the 2023 control period,[244] and affected EGUs within the borders of the five states not currently covered by any CSAPR trading program for seasonal NO_X emissions—Delaware, Minnesota, Nevada, Utah, and Wyoming—would enter the Group 3 trading program in the 2023 control period following the effective date of a final rule in this rulemaking. As is the case for the states already in the Group 3 trading program, for each state added to the program, the set of affected EGUs would include new units as well as existing units and units located in Indian country within the state's borders as well as units not located in Indian country. Sections VII.B.2 and VII.B.3 of this proposed rule provide additional discussion of the proposed geographic expansion of the Group 3 trading program and the units in the expanded geography that would likely become subject to the program under the program's existing applicability provisions.

In addition to expanding the Group 3 trading program's geographic scope, the EPA proposes to modify the program's regulations prospectively to include certain enhancements to improve environmental outcomes. Two of the proposed enhancements would adjust the overall quantities of allowances available for compliance in the trading program in each control period so as to maintain the rule's selected control stringency and related EGU effective emissions rate performance level as the EGU fleet evolves. First, instead of establishing emissions budgets for all future years under the program at the time of the rulemaking, which cannot reflect future changes in the EGU fleet unknown at the time of the rulemaking, the EPA proposes to revise the trading program regulations to include a dynamic budgeting procedure. This procedure would calculate emissions budgets for control periods in 2025 and later years based on more current information about the composition and utilization of the EGU fleet, specifically data available from the 2023 ozone season and following (*e.g.,* for 2025, data from 2023; for 2026, data from 2024; etc.). (Associated revisions to the program's variability limits and unit-level allowance allocation procedures would coordinate these provisions with the revised budget-setting procedures.) Second, starting with the 2024 control period, the EPA proposes to annually recalibrate the quantity of accumulated banked allowances under the program to prevent the quantity of allowances carried over from each control period to the next from exceeding the target bank level, which would be revised to represent 10.5 percent of the sum of the state emissions budgets. Together, these enhancements would protect the intended stringency of the trading program against potential erosion caused by EGU fleet turnover and would better sustain over time the incentives created by the trading program to apply continuously the degree of emissions control the EPA determines is necessary to address states' good neighbor obligations.

Two further enhancements to the Group 3 trading program proposed in this rulemaking would establish provisions designed to promote more consistent emissions control by individual EGUs within the context of the trading program. First, starting with the 2024 control period for most coal-fired EGUs with existing SCR controls and the 2027 control period for most other coal-fired EGUs, a daily NO_X emissions rate of 0.14 lb/mmBtu would

[243] If any of the states whose sources currently participate in the Group 3 trading program is determined in the final rule to not have additional emissions reduction requirements for EGUs, the EPA proposes in the alternative to establish a new trading program substantially similar to the revised Group 3 trading program described in this proposal that would cover units within the borders of all the states determined to have emissions reduction requirements for EGUs in the final rule.

[244] Affected EGUs in the two other states currently covered by the Group 2 trading program—Iowa and Kansas—would continue to participate in that program.

apply as a backstop to the more stringent seasonal emissions budgets. Each ton of emissions exceeding a unit's backstop daily emissions rate would incur a 3-for-1 allowance surrender ratio instead of the usual 1-for-1 allowance surrender ratio. Second, also starting with the 2024 control period, the trading program's existing assurance provisions, which require extra allowance surrenders from sources that are found responsible for contributing to an exceedance of the relevant state's ''assurance level'' (*i.e.,* currently 121 percent of the state's emissions budget), would be strengthened by the addition of another backstop requirement. Specifically, for any unit found responsible for contributing to an exceedance of the state's assurance level, the revised regulations would prohibit the unit's seasonal emissions from exceeding by more than 50 tons the emissions that would have resulted if the unit had achieved a seasonal average emissions rate equal to the higher of 0.10 lb/mmBtu or 125 percent of the unit's lowest previous seasonal average emissions rate under any CSAPR seasonal NO_X trading program.[245]

These two enhancements are designed to ensure that all individual units with SCR controls have strong incentives to continuously operate and optimize their controls, and also to ensure that even units without SCR controls have strong incentives to optimize their emissions performance when a state's assurance level might otherwise be exceeded. These enhancements are generally designed to ensure consistency with EPA's determination regarding the emissions control stringency needed from EGUs to eliminate significant contribution under the Step 3 multifactor analysis as discussed in Section VI of this proposed rule. Further, these enhancements are designed to provide greater assurance that emissions controls will be operated on all days of the ozone season and therefore necessarily on the days that turn out to be most critical for downwind ozone levels. The EPA expects that promoting more consistently good emissions performance by individual EGUs will also help address disparate impacts of pollution on overburdened communities from individual units that might otherwise have chosen not to optimize their emissions performance.

[245] The requirement would not apply for control periods during which the unit operated for less than 10 percent of the hours, and emissions rates achieved in such previous control periods would be excluded from the comparison.

1. Trading Program Background and Overview of Proposed Revisions

a. Current CSAPR Trading Program Design Elements and Identified Concerns

The use of allowance trading programs to achieve required emissions reductions from the electric power sector has a long history, rooted in the Clean Air Act Amendments of 1990. In Title IV of those amendments, Congress specified the design elements for a 48-state allowance trading program to reduce SO_2 emissions and the resulting acid precipitation. Building on the success of that first allowance trading program as a tool for addressing multi-state air pollution issues, since 1998 EPA has promulgated and implemented multiple allowance trading programs for SO_2 or NO_X emissions to address the requirements of the CAA's good neighbor provision with respect to successively more stringent NAAQS for fine particulate matter and ozone. Most of these trading programs have applied either exclusively or primarily to EGUs.

The EPA currently administers six CSAPR trading programs for EGUs (promulgated in CSAPR, the CSAPR Update, and the Revised CSAPR Update) that differ in the pollutants, geographic regions, and time periods covered and in the levels of stringency, but that otherwise are nearly identical in their core design elements and their regulatory text.[246] The principal common design elements currently reflected in all of the programs are as follows:

- An ''emissions budget'' is established for each state for each control period, representing EPA's quantification of the emissions that would remain under certain projected conditions after elimination of the emissions prohibited by the good neighbor provision under those projected conditions. For each control period of program operation, a quantity of newly issued ''allowances'' equal to the amount of each state's emissions budget is allocated among the state's sources. (States have options to replace EPA's default allocations or to institute an auction process.) Total emissions in a given control period from all sources in the program are effectively capped at a level no higher than the total quantity of allowances available for use in the control period, consisting of the sum of all states' emissions budgets for the control period plus any unused allowances carried over from previous control periods as ''banked'' allowances.
- ''Assurance provisions'' in each program establish an ''assurance level'' for each state for each control period, defined as the sum of the state's emissions budget plus a specified ''variability limit.'' The purpose of the assurance provisions is to limit the total emissions from each state's sources in each control period to an amount close to the state's emissions budget for the control period, consistent with the good neighbor provision's mandate that required emissions reductions must be achieved within the state, while allowing some flexibility beyond the emissions budget to accommodate year-to-year operational variability. In the event a state's assurance level is exceeded, responsibility for the exceedance is apportioned among the state's sources through a procedure that accounts for the sources' shares of the state's total emissions for the control period as well as the sources' shares of the state's assurance level for the control period.
- At the program's compliance deadlines after each control period, sources are required to hold for surrender specified quantities of allowances. The minimum quantities of allowances that must be surrendered are based on the sources' reported emissions for the control period at a 1-for-1 ratio of allowances to tons of emissions (or 2-for-1 in instances of late compliance). In addition, two more allowances must be surrendered for each ton of emissions exceeding a state's assurance level for a control period, yielding an overall 3-for-1 surrender ratio for those emissions (or 4-for-1 in instances of late compliance). Failure to timely surrender all required allowances is potentially subject to penalties under the CAA's enforcement provisions.
- To continuously incentivize sources to reduce their emissions even when they already hold sufficient allowances to cover their expected emissions for a control period, and to promote compliance cost minimization, operational flexibility, and allowance market liquidity, the programs allow trading of allowances—both among sources in the program and with non-source entities—and also let allowances that are unused in one control period be carried over for use in future control periods as banked allowances. Although the programs do not directly limit either trading or banking of allowances, the 3-for-1 surrender ratio imposed by the

[246] The six current CSAPR trading programs are the CSAPR NO_X Annual Trading Program, CSAPR NO_X Ozone Season Group 1 Trading Program, CSAPR SO_2 Group 1 Trading Program, CSAPR SO_2 Group 2 Trading Program, CSAPR NO_X Ozone Season Group 2 Trading Program, and CSAPR NO_X Ozone Season Group 3 Trading Program. The regulations for the six programs are set forth at subparts AAAAA, BBBBB, CCCCC, DDDDD, EEEEE, and GGGGG, respectively, of 40 CFR part 97.

assurance provisions on any emissions exceeding a state's assurance level disincentivizes sources from relying on either in-state banked allowances or net out-of-state purchased allowances to emit over the assurance level.

• Finally, other common design elements ensure program integrity, source accountability, and administrative transparency. Most notably, each unit must monitor and report emissions and operational data in accordance with the provisions of 40 CFR part 75; all allowance allocations or auction results, transfers, and deductions must be properly recorded in EPA's Allowance Management System; each source must have a designated representative who is authorized to represent all of the source's owners and operators and is responsible for certifying the accuracy of the source's reports to the EPA and overseeing the source's Allowance Management System account; and comprehensive data on emissions and allowances are made publicly available.

The EPA continues to believe that the current CSAPR trading program structure established by the common design elements described previously has important positive attributes, particularly with respect to the exceptional degree of compliance flexibility it can provide to a sector such as the electric power sector where such flexibility is especially useful and valuable. However, the EPA also shares some stakeholders' concerns about whether the current structure, without enhancements, is capable of adequately addressing states' good neighbor obligations with respect to the 2015 ozone NAAQS in light of the rapidly evolving EGU fleet and the stringency and short-term form of the standard. One set of concerns relates to the observed tendency under the current trading programs for the supply of allowances to grow over time while the demand for allowances falls, reducing allowance prices and eroding the consequent incentives for sources to effectively control their emissions. A second, overlapping set of concerns relates to the general absence of source- or unit-specific emissions reduction requirements, allowing some individual sources to idle existing emissions controls. Emissions from these individual sources can contribute to increased pollution concentrations downwind on the particular days that matter for downwind exceedances of the relevant air quality standard and also have the potential to cause disproportionate adverse impacts on downwind overburdened communities. The EPA has analyzed hourly emissions data reported in prior cap-and-trade programs and identified instances of sources that did not operate SCR controls for substantial portions of recent ozone seasons. In an effort to maintain as much compliance and operational flexibility as possible, ensure controls happen on critically important highest ozone days, guard against this behavior under a more stringent NAAQS, and provide relief to overburdened communities, the EPA would require control operation every day through a unit-level emission rate designed to ensure reductions occur on the highest ozone days in addition to maintaining a mass-based seasonal requirement. To meet the statutory requirement to eliminate significant contribution and interference with maintenance on the critically important days, this combination of requirements would require sources to plan to run controls all season, including the highest ozone days, while giving reasonable flexibility for occasional operational needs.

In this rulemaking, the EPA is proposing to revise the Group 3 trading program to include enhancements designed to address both sets of concerns described above.[247] The principles guiding the various proposed revisions and the relationships of the revisions to one another are discussed in Sections VII.B.1.b and VII.B.1.c of this proposed rule. The individual proposed revisions are discussed in more detail in Sections VII.B.4 through VII.B.9 of this proposed rule.

b. Enhancements To Maintain Selected Control Stringency Over Time

The first set of concerns noted about the current CSAPR trading program structure relates to the programs' ability to maintain the rule's selected control stringency and related EGU effective emissions rate performance level as the EGU fleet evolves over time. Under the structure of the current CSAPR trading programs, the effectiveness of the programs at maintaining the rule's selected control stringency depends entirely on how allowance prices over time compare to the costs of sources' various emissions reduction opportunities, which in turn depends on the relationship between the supply for allowances and the demand for allowances. In considering possible ways to address concerns about the ability to enhance the current trading program structure to better sustain incentives to control emissions over time, the EPA has focused on the trading program design elements that determine the supply of allowances, specifically the approach for setting state emissions budgets and the rules concerning the carryover of unused allowances for use in future control periods as banked allowances.

i. Revised Emissions Budget-Setting Process

In each of the previous rulemakings establishing CSAPR trading programs, the EPA has evaluated the emissions that could be eliminated through implementation of certain types of emissions control strategies available at various cost thresholds to achieve certain rates of emissions per unit of heat input (*i.e.,* the amount of fuel consumed) and the effects of the resulting emissions reductions on downwind air quality. After determining the emissions control strategies and associated emissions reductions that should be required under the good neighbor provision by considering these factors in a multifactor test, the EPA has then projected the amounts of emissions that would remain after the assumed implementation of the selected emissions control strategies at various points in the future and has established the projected remaining amounts of emissions as the state emissions budgets in trading programs.

Projecting the amounts of emissions remaining after implementation of selected emissions controls necessarily requires projections not only for sources' future emissions rates but also for other factors that influence total emissions, notably the composition of the future EGU fleet (*i.e.,* the capacity amounts of different types of sources with different emissions rates) and their future utilization levels (*i.e.,* their heat input). To the extent the projections made at the time of a rulemaking for these other factors prove inaccurate, over time the emissions budgets may not reflect the intended stringency of the emissions control strategies identified in the rulemaking as consistent with addressing states' good neighbor obligations. Further, projecting EGU fleet composition and utilization has become increasingly challenging in light of the rapid evolution of the electric power sector toward more efficient and cleaner sources of generation, driven by factors including lower prices for natural gas and wind and solar generation.

[247] With the exception of the proposed conforming revisions to allowance recordation schedules discussed in Section VII.B.12 of this proposed rule, the EPA is not proposing in this rulemaking to extend the enhancements proposed for the Group 3 trading program to the other CSAPR trading programs.

A consequence of using a trading program approach with preset emissions budgets that do not keep pace with the trends in EGU fleet composition and heat input is that the preset emissions budgets maintain the supply of allowances at levels that increasingly exceed the emissions that would occur even without implementation of the emissions control strategies used as the basis for determining the emissions budgets, causing decreases in allowance prices and hence the incentives to implement the control strategies. As an example, although the emissions budgets in the CSAPR Update established in 2016 reflected implementation of the emissions control strategy of operating and optimizing existing SCR controls, within 4 years the EPA found that EGU retirements and changes in utilization not anticipated in EPA's previous budget-setting computations had made it economically attractive for at least some sources to idle or reduce the effectiveness of their existing controls (relying on purchased allowances instead).[248] While the EPA has provided analysis indicating that, on average, sources operate their controls more effectively on high electric demand days, it has also identified cases where units fail to optimize their controls on these days. Downwind states have suggested this type of reduced pollution control performance has occurred on the day and preceding day of an ozone exceedance.[249] [250] Such an outcome undermined the ongoing achievement of emissions rate performance consistent with the control strategies defined to eliminate significant contribution to nonattainment and interference with maintenance, including continuous operation and optimization of existing controls.

In the Revised CSAPR Update, the EPA took steps to better address the rapid evolution of the EGU fleet, specifically by setting updated emissions budgets for individual future years though 2024 that reflect future EGU fleet changes known with reasonable certainty at the time of the rulemaking. Some commenters requested that the EPA also update the year-by-year emissions budgets to reflect future fleet changes that might become known after the time of the rulemaking, but the EPA declined to do so, in part because no methodology for making future emissions budget adjustments in response to post-rulemaking data had been included in the proposal for the rulemaking.

Based on information available as of December 2021, it appears that the emissions budgets set for the first control period covered by the Revised CSAPR Update generally succeeded at creating incentives to operate emissions controls under the Group 3 trading program for the programs' first control period. However, the EPA recognizes that the lack of emissions budget adjustments after 2024 in conjunction with industry trends toward more efficient and cleaner resources would likely lead to a surplus of allowances after the adjustments end. In this rulemaking, besides setting new emissions budgets for the 2023 and 2024 control periods, the EPA also proposes to extend the Group 3 trading program budget-setting methodology used in the Revised CSAPR Update to routinely set emissions budgets for each future control period in the year before that control period, with each emissions budget reflecting the latest available information on the composition and utilization of the EGU fleet at the time that emissions budget is determined.

The current budget-setting methodology established in the Revised CSAPR Update and the proposed revisions are discussed in detail in Section VII.B.4 of this proposed rule and the Ozone Transport Policy Analysis Proposed Rule TSD. To summarize here, the Revised CSAPR Update's emissions budget-setting methodology includes three primary steps: (1) Establishment of a baseline inventory of EGUs adjusted for known retirements and new units, with heat input and emissions rate data for each EGU in the inventory based on recent historical data; (2) adjustment of the baseline data to reflect assumed emissions rate changes resulting from known new controls, known gas conversions, and implementation of the emissions control strategies used to determine states' good neighbor obligations; and (3) application of an increment or decrement to reflect the effect on emissions from projected generation shifting among the units in a state at the emissions reduction cost associated with the selected emissions control strategies. In this rulemaking, the EPA proposes to modify this methodology in two ways. First, the baseline EGU inventory and heat input data, but not the emissions rate data, would be updated for each control period using the most recent available reported data. For example, in early 2024, using the final data reported for 2023, the EPA would update the baseline inventory and heat input data used to determine state emissions budgets for the 2025 control period. Second, the EPA would not apply an increment or decrement to any state emissions budget for projected generation shifting associated with implementation of the selected control strategies, because any such shifting should already be reflected in the heat input data used to update the baseline.[251]

The EPA believes that the proposed revisions to the emissions budget-setting process would substantially improve the ability of the emissions budgets to keep pace with changes in the composition and utilization of the EGU fleet. The revised methodology would account for the electric power sector's overall trends toward more efficient and cleaner resources, both of which tend to decrease total heat input at affected EGUs. The revised methodology would also account for other factors that could lead to increased heat input in some states, such as generation shifting from other states or increases in electricity demand caused by rising electrification. The updating procedure would be specified in the program regulations and the computations, which would be straightforward, could be performed in a spreadsheet to deliver reliable results. EPA would provide public notice of the preliminary calculations and the data used by March 1 of the year preceding the control period and would provide an opportunity for submission of any objections to the data and preliminary calculations before finalizing the budgets for each control period by May 1 of the year before the control period to which those budgets apply. Thus, for example, sources and other stakeholders will have certainty by May 1, 2024, of the emissions budgets that will be set for the 2025 control period that starts May 1, 2025.

[248] The price of allowances in CSAPR Update states started out at levels near $800 per ton in 2017 but declined to less than $100 per ton by 2019 and were less than $70 per ton in July 2020 (data from S&P Global Market Intelligence).

[249] 86 FR 23117.

[250] *See EPA–HQ–OAR–2020–0272–0094.* ''. . . is demonstrated through examination of Maryland's ozone design value days for June 26th–28th, 2019. On those days, Maryland recorded 8-hour ozone levels of 75, 85 and 83 ppb at the Edgewood monitor. Maryland Department of the Environment evaluated the daily NO_X emission rate for units in Pennsylvania that were found to influence the design values on the 3 exceedance days (and 1 day prior to the exceedance) against the past-best ozone season 30-day rolling average optimized NO_X rate (which tends to be higher than the absolute lowest seasonal average rate).''

[251] Emission reductions derived from generation shifting will be captured in the dynamic budgets in all cases. For the pre-set budget years it is estimated and incorporated through an additional calculation step. For dynamic budget years, it is directly incorporated through the inclusion of updated heat input data reflecting observed, compliance period generation shifting.

It bears emphasis that the annually updated information would concern only the composition and utilization of the EGU fleet and not the emissions rate data also used in the emissions budget computations. The emissions budget computations for all years would reflect only the specific emissions control strategies used to determine states' good neighbor obligations as determined in this rulemaking, along with fixed historical emissions rates for units that are not assumed to implement additional control strategies, thereby ensuring that the annual updates would eliminate emissions as determined to be required under the good neighbor provision. The stringency of the emissions budgets would simply reflect the stringency of the emissions control strategies determined in the Step 3 multifactor analysis and would do so more consistently over time than EPA's previous approach of computing emissions budgets for all future control periods at the time of the rulemaking.

The proposed revisions to state emissions budgets and the budget-setting process are discussed further in Section VII.B.4 of this proposed rule. Proposed coordinated revisions to the determination of state-level variability limits and assurance levels and to unit-level allowance allocations are discussed in Sections VII.B.5 and VII.B.9 of this proposed rule, respectively.

ii. Allowance Bank Recalibration

Besides the levels of the emissions budgets, the second design element of the trading program structure that affects the supply of allowances in each control period, and that consequently also affects the ability of a trading program to maintain the rule's selected control stringency and related EGU effective emissions rate performance level as the EGU fleet evolves over time, is the set of rules concerning the carryover of unused allowances for use in future control periods as banked allowances. As noted previously, trading and banking of allowances in the CSAPR trading programs can serve a variety of purposes: Continuously incentivizing sources to reduce their emissions even when they already hold sufficient allowances to cover their expected emissions for a control period, facilitating compliance cost minimization, accommodating necessary operational flexibility, and promoting allowance market liquidity. All of these purposes are advanced by rules that allow sources to trade allowances freely (both with other sources and with non-source entities such as brokers). All of these purposes are also advanced by rules that allow unused allowances to be carried over for possible use in future control periods, thereby preserving a value for the unused allowances. However, while the EPA considers it generally advantageous to place as few restrictions on the trading of allowances as possible,[252] unrestricted banking of allowances has a potentially significant disadvantage offsetting its advantages, namely that it allows what might otherwise be temporary surpluses of allowances in some individual control periods to accumulate into a long-term allowance surplus that reduces allowances prices and weakens the trading program's incentives to control emissions. With weakened incentives, some operators would be more likely to choose not to continuously operate and optimize their emissions controls, imperiling the ongoing achievement of emissions rate performance consistent with the control strategies defined as eliminating significant contribution to nonattainment and interference with maintenance.

As discussed in detail in Section VII.B.6 of this proposed rule, the EPA is proposing to revise the Group 3 trading program by adding provisions that would establish a routine recalibration process for banked allowances that would be carried out in August 2024 and each subsequent August, after the compliance deadline for the control period in the previous year. In each recalibration, the EPA would reset the total quantity of banked allowances for the Group 3 trading program (''Group 3 allowances'') held in all Allowance Management System accounts to a target level of 10.5 percent of the sum of the state emissions budgets for the current control period. The procedure would entail identifying the ratio of the target bank amount to the total quantity of banked allowances held in all accounts before the conversion and then, if the ratio was less than 1.0, multiplying the quantity of banked allowances held in each account by the ratio to identify the appropriate recalibrated amount for the account (rounded to the nearest allowance), and deducting any allowances in the account exceeding the recalibrated amount.

The EPA believes this revision to the Group 3 trading program's banking provisions would complement the proposed revisions to the budget-setting process by ensuring that the annual bank recalibration would prevent any surplus of allowances created in one control period from diminishing the intended stringency and resulting emissions reductions of the emissions budgets for subsequent control periods.[253]

The calibration procedure would not erase the value of unused allowances for the holder, because the larger the quantity of banked allowances that is held in a given account before each recalibration, the larger the quantity of banked allowances that would be left in the account after the recalibration for possible sale or use in meeting future compliance requirements. Because the banked allowances would always have value, the opportunity to bank allowances would continue to advance the purposes served by otherwise unrestricted banking as described above. Opportunities to bank unused allowances can serve all these same purposes whether a banked allowance is of partial value (if the bank needs recalibrating to its target level) or is of full value compared to a newly issued allowance for the next control period.

The proposal to routinely recalibrate the allowance bank is discussed further in Section VII.B.6 of this proposed rule.

d. Enhancements To Improve Emissions Performance at Individual Units

The second set of concerns about the structure of the current CSAPR trading programs relates to the general absence of source- or unit-specific emissions reduction requirements. Without such requirements, the programs affect individual sources' emissions

[252] The advantages of trading programs discussed earlier in this section—providing continuous emissions reduction incentives, facilitating compliance cost minimization, and supporting operational flexibility—depend on the existence of a marketplace for purchasing and selling allowances, and broader marketplaces generally provide greater market liquidity and therefore make trading programs better at providing these advantages. The EPA recognizes that unrestricted use of *net* purchased allowances—meaning quantities of purchased allowances that exceed the quantities of allowances sold—by a source or group of sources as an alternative to making emissions reductions can interfere with the achievement of the desired environmental outcome, and Section VII.B.1.c of this proposed rule discusses the enhancements to the Group 3 trading program that the EPA is proposing in this rulemaking to reduce reliance on net purchased allowances by incentivizing or requiring better environmental performance at individual EGUs. However, the concern arises from the *use of an excessive quantity* of net purchased allowances for a particular purpose, not from the existence of a *marketplace* where allowances may be freely bought and sold.

[253] The EPA recognizes there will be a data lag inherent in the future year emissions budgets, because the budgets would reflect fleet composition and utilization data reported for a previous control period. This means that the budgets for some individual control periods may fail to fully keep pace with the EGU fleet's trends toward more efficient and cleaner resources. Nonetheless, the new approach is a substantial improvement in environmental performance of the program compared to a more unlimited approach to allowance banking.

performance only to the extent that the incentives created by allowance prices are high enough relative to the costs of the sources' various emissions control opportunities. In circumstances where the incentives to control emissions are insufficient, some individual sources even idle existing emissions controls. Emissions from these individual sources can contribute to increased pollution concentrations downwind on the particular days that matter for downwind exceedances of the relevant air quality standard and also have the potential to cause disproportionate adverse impacts on downwind overburdened communities.

This EPA intends that the trading program enhancements described in Section VII.B.1.b of this proposed rule would improve the Group 3 trading program's ability to sustain emissions control incentives over time such that needed emissions performance would be achieved by all participating units without the need for additional requirements to be imposed at the level of individual units. However, because obtaining needed emissions performance at individual units is also important, the EPA proposes to supplement the previously discussed enhancements with two other new sets of provisions that would apply to certain individual units within the larger context of the Group 3 trading program. The allowance price would continue to be the most important driver of good environmental performance for most units, but the proposed unit-level requirements would be important supplemental drivers of performance and would offer additional assurance that significant contribution is eliminated on a daily basis during the ozone season by continuous operation of existing pollution controls.

i. Unit-Specific Backstop Daily Emissions Rates

The first of the proposed trading program enhancements intended to improve emissions performance at the level of individual units is the addition of backstop daily NO_X emissions rate provisions that would apply to large coal-fired EGUs, defined for this purpose as units serving electricity generators with nameplate capacities equal to or greater than 100 MW and combusting any coal during the control period in question. Starting with the 2024 control period, a 3-for-1 allowance surrender ratio (instead of the usual 1-for-1 surrender ratio) would apply to emissions during the ozone season from any large coal-fired EGU with existing SCR controls exceeding a daily average NO_X emissions rate of 0.14 lb/mmBtu. The additional allowance surrender requirement would be integrated into the trading program as a new component in the calculation of each unit's primary emissions limitation, such that the additional allowances would have to be surrendered by the same compliance deadline of June 1 after each control period. The amount of additional allowances to be surrendered would be determined by computing, for each day of the control period, any excess of the unit's reported emissions (in pounds) over the emissions that would have resulted from combusting that day's actual heat input at an average daily emissions rate of 0.14 lb/mmBtu, summing the daily amounts, converting from pounds to tons, and multiplying by two. Starting with the 2027 control period, the 3-for-1 surrender ratio would apply in the same way to all large coal-fired EGUs, consistent with EPA's proposed determinations, first, that a control stringency reflecting installation and operation of SCR controls on all large coal-fired EGUs is appropriate to address states' good neighbor obligations with respect to the 2015 ozone NAAQS, and second, that such controls could reasonably be installed by the 2026 control period.

In prior rules addressing interstate transport of air pollution, stakeholders have noted that while seasonal cap-and-trade programs are effective at lowering ozone and ozone-forming precursors across the ozone season, attainment of the standard is measured on key days and therefore it is necessary to ensure that the rule requires emissions reductions not just seasonally, but also on those key days.[254] They have noted that while the trading programs established under the NO_X SIP Call, CAIR, and CSAPR have all been successful in ensuring seasonal reductions, states must remain below daily peak levels, not just seasonal levels, to reach attainment. These downwind stakeholder communities have suggested that operating pollution controls on the highest ozone days (and immediately preceding days) during the ozone season is of critical importance. The EPA has analyzed hourly emissions data reported in prior cap-and-trade programs and has identified instances of sources that did not operate SCR controls for substantial portions of recent ozone seasons. These instances are discussed below and in the EGU NO_X Mitigation Strategies Proposed Rule TSD in the docket. While the EPA has in prior ozone transport actions not found sufficient evidence of emissions control idling or non-operation to take the step of building in enhancements to the trading program to ensure unit-level control operation, our review of that information applied to this context suggests this problem could become more prevalent in future years relevant to this action. Rather than allow for the potential of continued deterioration in the environmental performance of our trading programs, the EPA finds the evidence of declining SCR performance in later years of trading programs sufficient to justify prophylactic measures in this proposal to ensure the emissions control strategy selected at Step 3 is indeed implemented at Step 4. Thus, particularly in the context of the more stringent 2015 ozone NAAQS combined with the full remedy nature of this action and the extended timeframe for which upwind contribution to downwind nonattainment is projected to persist, the EPA agrees with these stakeholders that the set of measures promulgated in this rulemaking to implement the control stringency levels found necessary to address states' good neighbor obligations should include measures designed to more effectively ensure that individual units operate their emission controls routinely throughout the ozone season, thereby also ensuring that the controls are planned to be in operation on the particular days that turn out to be most critical for ozone formation and for attainment of the NAAQS.[255] Routine operation of emissions controls will also provide relief to overburdened communities downwind of any units that might otherwise have chosen not to operate their controls. In the Ozone Transport TSD, the EPA conducted a screening analysis that found nearly all of the EGUs included in this analysis are located within a 24-hour transport distance of many areas with potential EJ concerns. The EPA is proposing to adopt backstop daily rate limits at the individual unit level for this purpose, implemented in the context of a trading program (*i.e.,* through enhanced allowance surrender ratios), as an alternative to adopting enforceable rate limits.

The purpose of establishing a backstop daily NO_X emissions rate and implementing it through additional

[254] EPA–HQ–OAR–2020–0272. Comment submitted by Ben Grumbles, Secretary, Maryland Department of the Environment (MDE).

[255] The CSAPR Update was a partial remedy and the Revised CSAPR Update addressed downwind nonattainment and maintenance issues that were projected to be resolved within a 4 year window. In contrast, this rule reflects a full remedy and is addressing downwind nonattainment and maintenance issues that are projected to persist for more than a decade.

allowance surrender requirements instead of as an enforceable rate limit is to incentivize improved emissions performance at the individual unit level while continuing to preserve, to the extent possible, the advantages that the flexibility of a trading program brings to the electric power sector. As discussed in Section VII.B.7 of this proposed rule, under existing trading programs without the enhancements proposed in this rulemaking, some individual coal-fired units with SCR controls have chosen to operate the controls at lower removal efficiencies than in past ozone seasons or even to idle the controls for entire ozone seasons. In addition, some SCR-equipped units have chosen to routinely cycle their emissions controls off at lower load levels, such as while operating overnight, instead of operating the controls, upgrading the units to enable the controls to be operated under those conditions, or not operating the units under those conditions.

The EPA has identified sources of interstate ozone pollution such as the New Madrid and Conemaugh plants (in Missouri and Pennsylvania, respectively) whose SCR controls were not operating for substantial portions of recent ozone seasons. The data in Figures 1 and 2 to Section VII.B.1.c.i, included in Appendix G of the Ozone Transport Policy Analysis Proposed Rule TSD available in the docket for this rulemaking, demonstrate that these units have operated their SCRs better and more consistently during years with higher NO_X allowance prices. Downwind stakeholders have noted that some of the higher emission rates (specifically in the case of Conemaugh Unit 2 in 2019) have occurred on the day of and the preceding day of an ozone exceedance in bordering states.[256]

The EPA believes that the design of the proposed daily emissions rate provisions would be effective in addressing these types of high-emitting behavior by significantly raising the cost of planned operator decisions that substantially compromise environmental performance. At the same time, the provision would not unduly penalize an occasional unplanned exceedance, because the amount of additional allowances that would have to be surrendered to address a single day's exceedance would be much smaller than the amount that would have to be surrendered to address planned poor performance sustained over longer time periods.[257]

The EPA proposes to apply the daily emissions rate provisions to large coal-fired EGUs, and not to other types of units, for reasons that are consistent with EPA's determinations regarding the appropriate control stringency for EGUs to address states' good neighbor obligations with respect to the 2015 ozone NAAQS. Installation and operation of SCR controls is well-established as best practice for control of NO_X emissions from coal-fired EGUs, as evidenced by the fact that the technology is already installed on more than 60 percent of the sector's total coal-fired capacity. In the context of the need for states to address their good neighbor obligations with respect to the 2015 ozone NAAQS, the EPA is proposing to determine that a control stringency reflecting universal installation and operation of SCR technology at large coal-fired EGUs is appropriate, based on a multi-factor test that includes consideration of cost-effectiveness along with air quality factors. Finally, where SCR controls are installed, optimized operation of those controls is an extremely cost-effective method of achieving NO_X emissions reductions. The EPA believes these considerations support establishment of the proposed daily emissions rate provisions on a universal basis for large coal-fired EGUs, with near-term application of the provisions for units that already have the controls installed and deferred application for other units, as discussed later.

With regard to gas-fired steam EGUs, SCR controls are nowhere near as prevalent, and while the EPA is proposing to include some SCR controls at gas-fired steam units in the selected control stringency, the EPA is not proposing to include universal SCR controls at gas-fired steam units. Because the EPA does not propose to determine that universal installation and operation of SCR controls at gas-fired steam EGUs is part of the selected control stringency, in order not to constrain the power sector's flexibility to choose which particular gas-fired steam EGUs are the preferred candidates for achieving the required emissions reductions, the EPA is not proposing to apply the daily emissions rate provisions to large gas-fired steam EGUs. Focusing the backstop daily emissions rates on coal-fired units is also consistent with stakeholder input which has emphasized the need for short-term rate limits at coal units given their relatively higher emissions rates.

The EPA developed the proposed level of the daily average NO_X emissions rate—0.14 lb/mmBtu—through analysis of historical data, as described in Section VII.B.7 of this proposed rule. A rate of 0.14 lb/mmBtu represents the daily average NO_X emissions rate that has been demonstrated to be achievable on approximately 95 percent of days covering more than 99 percent of total ozone-season NO_X emissions by coal-fired units with SCR controls that are achieving a seasonal NO_X average emissions rate of 0.08 lb/mmBtu (or less), which is the seasonal NO_X emissions rate that the EPA has determined is indicative of optimized SCR performance by units with existing SCR controls.

As noted previously, the daily average emissions rate provisions are proposed to apply beginning in the 2024 control period for large coal-fired units with installed SCR controls, one control period later than optimization of those controls would be reflected in the state emissions budgets under the proposal. Likewise, the daily average emissions rate provisions are proposed to apply beginning in the 2027 control period for other large coal-fired units, one control period later than emissions reductions consistent with the installation and operation of SCR controls for such units would be reflected in the state emissions budgets under the proposal. With respect to the units with existing SCR controls, not applying the daily average rate provisions until 2024 would serve two purposes. First, it would provide all the units with a preparatory interval to focus attention on improving not only the average performance of their SCR controls but also the day-to-day consistency of performance before they would be held to increased allowance-surrender consequences for exceeding the daily rate. Second, it would provide the subset of units that exhaust to common stacks with other units that currently lack SCR controls an opportunity to exercise the option to install and certify any additional monitoring systems needed to monitor the individual units' NO_X emissions rates separately; otherwise, the daily emissions rate provisions would apply to the SCR-equipped units based on the combined

[256] EPA–HQ–OAR–2020–0272–0094.

[257] While the proposed design of the daily emissions rate provision would not deter another theoretical type of poor emissions control behavior—*i.e.,* turning off emissions controls at times of peak electricity demand in order to sell the additional electricity that otherwise would have been used to run the control equipment—EPA's analysis of hourly emissions data does not show that this behavior is actually occurring. The data actually suggest the opposite—that emissions controls are generally operated better on peak demand days than on other days. *See* the Ozone Policy Analysis Proposed Rule TSD for additional details about the assessment of the tons and the Discussion of Short-term Emissions Limit document for an assessment of control operation on peak demand days.

NO_X emissions rates measured in the common stacks.[258]

With respect to the units without existing SCR controls, not applying the daily average emissions rate provisions until 2027 would also serve two purposes. First, it would provide a window for plant personnel to gain experience operating any new SCR controls, and second, it would provide some timing flexibility for any individual unit operators who fail to complete SCR control installations before the start of the 2026 control period. With respect to both sets of units, the EPA believes that the lag in applicability of one control period is permissible because the emissions budget provisions are the principal provisions intended to drive the emissions reductions required under the proposal, while the daily average emissions rate provisions are included only to backstop those provisions.

The EPA believes that the proposed unit-specific daily emissions rate provisions would strengthen the incentives for individual coal-fired units with SCR controls to operate and optimize performance of the controls. Continuous operation and optimization of post-combustion controls at individual units would help address individual days that prove in real time to be most critical for downwind ozone levels. Better continuous emissions performance by individual units would also help address disparate impacts of pollution on overburdened communities downwind from the units.

The proposed unit-specific target daily emissions rates are discussed further in Section VII.B.7 of this proposed rule.

ii. Unit-Specific Emissions Limitations Contingent on Assurance Level Exceedances

The second of the proposed trading program enhancements intended to improve emissions performance at the level of individual units is the addition of unit-specific secondary emissions limitations. The secondary emissions limitations would be determined on a unit-specific basis according to each unit's individual performance but would apply to a given unit only under the circumstance where a state's assurance level for a control period has been exceeded, the unit is included in a group of units to which responsibility for the exceedance has been apportioned under the program's assurance provisions, and the unit operated during at least 10% of the hours in the control period. Where these conditions for application of a secondary emissions limitation to a given unit for a given control period are met, the unit's secondary emissions limitation would consist of a prohibition on NO_X emissions during the control period that exceed by more than 50 tons the NO_X emissions that would have resulted if the unit had achieved an average emissions rate for the control period equal to the higher of 0.10 lb/mmBtu or 125 percent of the unit's lowest average emissions rate for any previous control period under any CSAPR seasonal NO_X trading program during which the unit operated for at least 10 percent of the hours.

The proposed secondary emissions limitation would be in addition to, not in lieu of, the primary emissions limitation applicable to each source, which would continue to take the form of a requirement to surrender a quantity of allowances based on the source's emissions, and also in addition to the existing assurance provisions, which similarly would continue to take the form of a requirement for the owners and operators of some sources to surrender additional allowances when a state's assurance level is exceeded. In contrast to these other requirements, the proposed unit-specific secondary emissions limitation would take the form of a prohibition on emissions over a specified level, such that any emissions by a unit exceeding its secondary emissions limitation would be subject to potential administrative or judicial action and subject to penalties and other forms of relief under the CAA's enforcement authorities. The reason for proposing this form of limitation is that experience under the existing CSAPR trading programs has shown that, in some circumstances, the existing assurance provisions have been insufficient to prevent exceedances of a state's assurance level for a control period even when the likelihood of an exceedance has been foreseeable and the exceedance could have been readily avoided if certain units had operated with emissions rates closer to the lower emissions rates achieved in past control periods. The assurance levels exist to ensure that emissions from each state that contribute significantly to nonattainment or interfere with maintenance of a NAAQS in another state are prohibited. *North Carolina* v. *EPA,* 531 F.3d 896, 906–908 (D.C. Cir. 2008). EPA's programs to eliminate significant contribution must therefore achieve this prohibition, and the new evidence of exceedances of the assurance provisions demonstrate that EPA's existing approach may not be sufficient to accomplish this statutory mandate.

The purpose of including assurance levels higher than the state emissions budgets in the CSAPR trading programs is to provide flexibility to accommodate operational variability attributable to factors that are largely outside of an individual owner's or operator's control, not to allow owners and operators to plan to emit at emissions rates that could be anticipated to cause a state's total emissions to exceed the state's emissions budget or assurance level. Conduct leading to a foreseeable, readily avoidable exceedance of a state's assurance level cannot be reconciled with the statutory mandate of the CAA's good neighbor provision that emissions ''within the state'' significantly contributing to nonattainment or interfering with maintenance of a NAAQS in another state must be prohibited. Because the current CSAPR regulations do not expressly prohibit such conduct and have proven insufficient to deter it in some circumstances, the EPA is proposing to correct the regulatory deficiency in the Group 3 trading program by adding secondary emissions limitations that cannot be complied with through the use of allowances.

The EPA notes that although the principal purpose of the proposed secondary emissions limitations is to strengthen the assurance provisions, which apply on a statewide, seasonal basis, the unit-specific structure of the new limitations would strengthen the incentives for individual units to maintain their emissions performance at levels consistent with their previously demonstrated capabilities. For units with existing post-combustion emissions controls, the new limitations would strengthen the incentives to operate and optimize the controls continuously, and for units without such existing controls, the new limitations would strengthen the incentives to minimize NO_X emissions rates through other possible measures such as improved maintenance and optimization of combustion parameters. Continuous operation of post-combustion controls and greater attention to the combustion process at individual units can be expected to reduce some individual units' emissions rates throughout the ozone season, including on the days that turn out to be most critical for downwind ozone

[258] Based on the information reported by sources to the EPA in their monitoring plans under 40 CFR part 75, five plants subject to this proposal have SCR-equipped and non-SCR-equipped coal-fired EGUs that exhaust together to common stacks: The Clifty Creek plant in Indiana; the Cooper, Ghent, and Shawnee plants in Kentucky; and the Sammis plant in Ohio.

levels. Better emissions performance on average across the ozone season by individual units would also help address disparate impacts of pollution on overburdened communities downwind from some such units.

The proposed unit-specific secondary emissions limitations are discussed further in Section VII.B.8 of this proposed rule.

2. Expansion of Geographic Scope

As part of the proposed approach for implementing the NO_X emissions reductions from EGUs identified as necessary to address various states' obligations under the good neighbor provision with respect to the 2015 ozone NAAQS, the EPA is proposing to expand the existing geographic scope of the existing CSAPR NO_X Ozone Season Group 3 Trading Program to encompass the additional states (and Indian country within the borders of such states) found to have such obligations with respect to EGUs. Specifically, the EPA is proposing to expand the Group 3 trading program to include the following states and Indian country within the borders of the states: Alabama, Arkansas, Delaware, Minnesota, Mississippi, Missouri, Nevada, Oklahoma, Tennessee, Texas, Utah, Wisconsin, and Wyoming. Any unit located in a newly added jurisdiction that meets the existing applicability criteria for the Group 3 trading program would become an affected unit under the program, as discussed in Section VII.B.3 of this proposed rule.

CSAPR, the CSAPR Update, and the Revised CSAPR Update also applied to sources in Indian country, although, when those rules were issued, no existing EGUs within the regions covered by the rules were located on lands that the EPA understood at the time to be Indian country.[259] In contrast, within the proposed geographic scope of this rulemaking, the EPA is aware of areas of Indian country within the borders of both Utah and Oklahoma with existing EGUs that would meet the program's applicability criteria. Issues related to state, tribal, and federal jurisdiction with respect to sources in Indian country in general and in these areas in particular are discussed in Section IV.C.2 of this proposed rule.

EPA's proposed approach for determining a portion of each state's budget for each control period that would be set aside for allocation to any units in areas of Indian country within the state not subject to the state's CAA implementation planning authority is discussed in Section VII.B.9 of this proposed rule.

Units in each state would join the Group 3 trading program on one of two possible dates during the program's 2023 control period (that is, the period from May 1, 2023, through September 30, 2023). The reason that two entry dates are possible is that, as discussed in Section VII.B.11 of this proposed rule, the effective date of a final rule in this rulemaking may fall after May 1, 2023. In the case of states (and Indian country within the states' borders) whose sources do not currently participate in the CSAPR NO_X Ozone Season Group 2 trading program—Delaware, Minnesota, Nevada, Utah, and Wyoming—EPA proposes that the sources would begin participating in the Group 3 trading program on the later of May 1, 2023, or the final rule's effective date. However, in the case of the states (and Indian country within the states' borders) whose sources do currently participate in the Group 2 trading program—Alabama, Arkansas, Mississippi, Missouri, Oklahoma, Tennessee, Texas, and Wisconsin—EPA proposes that the sources would begin participating in the Group 3 trading program on May 1, 2023, regardless of the final rule's effective date, subject to transitional provisions designed to ensure that the increased stringency of the Group 3 trading program as revised in this rulemaking would not substantively affect the sources' requirements prior to the rule's effective date. This approach provides a simpler transition for the sources currently covered by the Group 2 trading program than the alternative approach of being required to switch from the Group 2 trading program to the Group 3 trading program in the middle of a control period, and it is the same approach that was followed for sources that transitioned from the Group 2 trading program to the Group 3 trading program in 2021 under the Revised CSAPR Update. Section VII.B.11 of this proposed rule contains further discussion of the rationale for this approach and the specific proposed transitional provisions.

The EPA notes that under the proposed rule, the expanded Group 3 trading program would include not only the 22 states for which the EPA is proposing to determine that the required control stringency includes, among other measures, installation of new post-combustion controls, but also the three states—Alabama, Delaware, and Tennessee—for which the EPA is proposing to determine that the required control stringency does not include such measures. In previous rulemakings, the EPA has chosen to combine states in a single multi-state trading program only where the selected control stringencies were comparable, in order to ensure that states did not effectively shift their emissions reduction requirements to other states with less stringent emissions reduction requirements by using net out-of-state purchased allowances. Although the assurance provisions in the CSAPR trading programs were designed to address the same general concern about excessive shifting of emissions reduction activities between states, EPA chose not to rely on the assurance provisions as sufficient to allow for interstate trading in situations where the states were assigned differing emissions control stringencies.

In this rulemaking, the EPA believes the previous concern about the possibility that certain states might not make the required emissions reductions is sufficiently addressed through the various proposed enhancements to the design of the trading program, even where states have been assigned differing emissions control stringencies. First, the existing assurance provisions would be substantially strengthened through the addition of the unit-specific secondary emissions limitations discussed in Sections VII.B.1.c.ii and VII.B.8 of this proposed rule. Second, by ensuring that individual units operate their emissions controls effectively, the unit-specific backstop daily emissions rate provisions discussed in Sections VII.B.1.c.i and VII.B.7 of this proposed rule would necessarily also ensure that required emissions reductions occur within the state. With these enhancements to the design of the trading program, the EPA does not believe it would be necessary for sources in Alabama, Delaware, and Tennessee to be excluded from the revised Group 3 trading program simply because their emissions budgets would reflect a different selected emissions control stringency than the other states in the program.

The EPA requests comment on the proposed expansion of the geographic scope of the Group 3 trading program to include the states and areas of Indian country identified above. The EPA also requests comment on the proposed timing under which the two sets of states and Indian country within the

[259] CSAPR and the CSAPR Update both applied to EGUs located in areas within Oklahoma's borders that are now understood to be Indian country, consistent with the U.S. Supreme Court's decision in *McGirt* v. *Oklahoma,* 140 S. Ct. 2452 (2020) (and subsequent case law), clarifying the extent of certain Indian country within Oklahoma's borders. However, those rules were issued before the *McGirt* decision. *See* Section IV.C.2.a.

respective states' borders would be added to the program.

3. Applicability and Tentative Identification of Newly Affected Units

The Group 3 trading program generally applies to any stationary, fossil-fuel-fired boiler or stationary, fossil fuel-fired combustion turbine located in a covered state (or Indian country within the borders of a covered state) and serving at any time on or after January 1, 2005, a generator with nameplate capacity exceeding 25 MW and producing electricity for sale, with exemptions for certain cogeneration units and certain solid waste incineration units. To qualify for an exemption as a cogeneration unit, an otherwise-affected unit generally (1) must be designed to produce electricity and useful thermal energy through the sequential use of energy, (2) must convert energy inputs to energy outputs with efficiency exceeding specified minimum levels, and (3) may not produce electricity for sale in amounts above specified thresholds. To qualify for an exemption as a solid waste incineration unit, an otherwise-affected unit generally (1) must meet the CAA section 129(g)(1) definition of a ''solid waste incineration unit'' and (2) may not consume fossil fuel in amounts above specified thresholds. The complete text of the Group 3 trading program's applicability provisions and the associated definitions can be found at 40 CFR 97.1004 and 97.1002, respectively.

The EPA is not proposing in this rulemaking to revise the existing applicability provisions for the Group 3 trading program. Thus, any unit that is located in a newly added state and that meets the existing applicability criteria for the Group 3 trading program would become an affected unit under the program. The fact that the applicability criteria for all of the CSAPR trading programs are identical therefore is sufficient to establish that any units that are currently required to participate in another CSAPR trading program in any of the proposed additional states where such other programs currently are in effect—Alabama, Arkansas, Minnesota, Mississippi, Missouri, Oklahoma, Tennessee, Texas, and Wisconsin (including Indian country within the borders of such states)—would also become subject to the Group 3 trading program.

In the proposed additional states where other CSAPR trading programs are not currently in effect—Delaware, Nevada, Utah, and Wyoming (including Indian country within the borders of such states)—units already subject to the Acid Rain Program generally would also meet the applicability criteria for the Group 3 trading program, especially if the units are not capable of producing both electricity and useful thermal energy. Based on a preliminary screening analysis of the units in these states that currently report emissions and operating data to the EPA under the Acid Rain Program and that do not report the capability to produce both electricity and useful thermal energy, the Agency believes that all such units are likely to meet the applicability criteria for the Group 3 trading program.

Because the applicability criteria for the Acid Rain Program and the Group 3 trading program are not identical, it is possible that some units could meet the applicability criteria for one program but not the other. Using data reported to the U.S. Energy Information Administration, the EPA has identified 10 sources in Delaware, Nevada, Utah, and Wyoming (and Indian country within the borders of the states) with 27 units that appear to meet the general applicability criteria for the Group 3 trading program and that either (1) do not currently report NO_X emissions and operating data to the EPA under the Acid Rain Program or (2) currently report NO_X emissions and operating data to the EPA under the Acid Rain Program and also report the capability to produce both electricity and useful thermal energy. These units are listed in Table VII.B.3–1 of this proposed rule. For each of these units, the table shows the estimated historical heat input and emissions data that the EPA proposes to use for the unit when determining state emissions budgets if the unit is ultimately treated as subject to the Group 3 trading program.[260] The EPA currently lacks sufficient information to determine whether any of the units listed in the table meets all of the relevant criteria to qualify for an exemption from the Group 3 trading program as a cogeneration unit or a solid waste incineration unit.

TABLE VII.B.3–1—SELECTED EXISTING UNITS THAT COULD BE AFFECTED UNDER PROPOSAL

State	Facility ID	Facility name	Unit ID	Unit type	Estimated ozone season heat input (mmBtu)	Estimated ozone season average NO_X emissions rate (lb/mmBtu)	Notes
Delaware	591	Christiana	11	CT	1,974	0.2594	1
Delaware	591	Christiana	14	CT	1,816	0.2027	1
Delaware	52193	Delaware City Refinery	DCPP2	Boiler	872,824	0.0176	2
Delaware	52193	Delaware City Refinery	DCPP3	Boiler	2,380,430	0.0169	2
Delaware	52193	Delaware City Refinery	DCPP4	Boiler	1,374,817	0.0438	2, 3

[260] As discussed in Section VII.B.10.b of this proposed rule, the EPA expects that any unit that becomes subject to the Group 3 trading program pursuant to a final rule in this rulemaking and that does not already report emissions data to the EPA in accordance with 40 CFR part 75 would not be required to report emissions data or be subject to allowance holding requirements under the Group 3 trading program until May 1, 2024, because of the minimum time interval allowed for installation and certification of the required monitoring systems. Such a unit would not be taken into account for purposes of determining state emissions budgets and unit-level allocations under the Group 3 trading program until the 2024 control period. As indicated in the notes to Table VII.B.3–1 of this proposed rule, six of the listed units have reported to the Energy Information Administration that they plan to retire in 2023.

TABLE VII.B.3–1—SELECTED EXISTING UNITS THAT COULD BE AFFECTED UNDER PROPOSAL—Continued

Table notes:
[1] Unit already reports NO_X emissions and heat input data to the EPA under 40 CFR part 75 to comply with SIP requirements.
[2] Unit reports capability of producing both electricity and useful thermal energy.
[3] Unit already reports NO_X emissions and heat input data to EPA under 40 CFR part 75 for the Acid Rain Program.
[4] Unit has reported a planned retirement date of March 2023 to the Energy Information Administration.

The EPA requests comment on which existing units in Delaware, Nevada, Utah, and Wyoming and Indian country within the borders of such states would or would not meet the applicability criteria for the Group 3 trading program. In addition, with respect to each of the units listed in Table VII.B.3–1 of this proposed rule, the EPA requests comment, with supporting data, on whether the unit would or would not meet all relevant criteria set forth in 40 CFR 97.1004 and the associated definitions in 97.1002 to qualify for an exemption from the trading program as a cogeneration unit or a solid waste incineration unit (however, see Section VI.B.3 of this proposed rule). The EPA also requests comment, with supporting data, on whether the estimated historical heat input and emissions data identified for the units in Table VII.B.3–1 of this proposed rule are representative for the respective units.

4. New and Revised State Emissions Budgets

The EPA is quantifying budgets or budget formulas specific to each year to ensure that EGUs continue to be incentivized to implement the full extent of EPA's selected control stringency for future control periods. By doing so, the EPA is accounting for both scheduled and not-yet-scheduled fleet turnover in future years. For instance, if State X's budget was 5,000 tons in 2023 but there are 100 tons of emissions from a unit scheduled to retire at the end of that year and 50 tons expected from a new unit coming online by the following year, then the state emissions budget for 2024 will reflect these scheduled changes by establishing a budget of 5,000 tons − 100 tons + 50 tons = 4,950 tons for the subsequent year.

In the Revised CSAPR Update, the EPA included announced fleet changes in state emissions budgets. Several commenters applauded the merit of this approach and the importance of establishing emissions budgets that were robust to an evolving fleet while noting that ''fleet composition is changing constantly and can be exceedingly difficult to project'' leading to overstated emissions budgets to the extent that future retirements were not announced at the time of rule promulgation. Commenters added that ''to address this problem and prevent future unknown retirements from exacerbating this issue, the final rule should include a provision to make additional adjustments to the NO_X budgets based on newly discovered fleet changes.''[261] Commenters were suggesting a dynamic budget approach where the mitigation measures and control stringencies that constituted removal of significant contribution would be identified in a final rule, but the future year state budgets would be dynamic as the EPA applied those stringency assumptions to future year fleet composition data as it became available. While the stringency (reflected by assumed emissions rate for a mitigation technology), would be constant, the fleet composition (reflected by unit heat input) is dynamic. Multiplying the assumed emissions rate for each unit by the heat input for each unit and summing the results to the state level would provide a given year's state emissions budget, and thus under this approach the state emissions budgets would be dynamic as well.

The EPA is proposing a dynamic budget approach in this rule, where emissions budgets starting in the 2025 control period and beyond will be determined through ministerial actions subsequent to this rule's promulgation and based upon the formula described in this rule. This rule will determine the mitigation strategies, respective emissions rates, and formulas and methodologies to be applied to future year data, with which the EPA will perform ministerial actions to calculate emissions budgets for control periods in 2025 and each year thereafter. (Such actions will be publicly announced through notices of data availability (NODAs), similar to how other periodic ministerial actions to implement the trading programs are currently handled. And as with such other actions, interested parties will have the opportunity to seek corrections or administrative adjudication under 40 CFR part 78 if they believe any data used in making these calculations, or the calculations themselves, are in error.) In this manner, the state emissions budgets ultimately implemented for each such future control period will be a product of the data and formula promulgated in this

[261] EPA–HQ–OAR–2020–0272–0094.

action applied to future year reported data that is closer to that future control period and therefore more representative of the fleet for that future control period. As such, the budgets will more accurately reflect power sector composition in that future year and will therefore better achieve the desired environmental outcome over time.

For instance, 2025 budgets will be identified by May 1, 2024, using the latest available reported operational data at that time (2023 heat input data and fleet inventory) along with the formulas and emissions rates quantified in this rule. Therefore, if a unit retires in early 2023 but had not announced its upcoming retirement at the time of rule finalization, the dynamic budget approach would ensure that the budgets for future control periods starting in 2025 would reflect the identified control stringency applied to a fleet that reflects that retirement. If the EPA took an alternative approach of computing the 2025 budget with available data at the time final rule analysis was being conducted, this retirement would likely not be captured in the 2025 state emissions budget, which would lead to a budget that did not fully reflect the application of the identified control stringency. This approach has the advantage of mitigating uncertainty regarding future retirements, new builds, and existing fleet operational/dispatch changes in response to EGU inventory changes.

The example below illustrates the effectiveness of the dynamic budget. In the preset budget approach for 2026, the 2026 heat input is estimated based on the latest available heat input data at the time of rule promulgation (*e.g.,* 2021), which cannot reflect a subsequent fleet change in heat input values (column 2) due to an unanticipated retirement of one of the state's coal-fired units in late 2023. However, the dynamic budget would use 2024 heat input values as opposed to the 2021 heat input values as the latest representative values to inform the 2026 state emissions budget. Therefore, the heat input values in column 2 under the dynamic scenario reflect the change in fleet composition, and when multiplied by the relevant identified control stringency (to be identified when this rule is finalized), the corresponding tonnage (15,000 tons) summed in column 4 constitutes a state budget that better reflects the identified control stringency applied to the fleet composition for that year as opposed to the 17,000 tons in summed in the first table. As illustrated in the example, the dynamic variable is the heat input variable which changes over time to reflect the most representative EGU fleet.

	Preset Budget Appraoch (2026)			Dynamic Budget Approach (2026)		
	Preset Heat Input (tBtu)	Preset Emissions Rate (lb/mmBtu)	Preset Tons (Heat input X Emissions Rate)/2000	Updated Heat Input (tBtu)	Emissions Rate (lb/mmBtu)	Updated Tons (Heat Input X Emissions Rate)/2000
Coal Units	600	0.05	15,000	500	0.05	12,500
Gas Units	400	0.01	2,000	500	0.01	2,500
State Budget (tons)			**17,000**			**15,000**

The EPA requests comment on this dynamic budget approach, including the methodology, the start year, and the impacts.

With regard to the state emissions budgets for the 2023 and 2024 control periods promulgated in this rule, the EPA is using the best available data at the time of the proposed rule regarding retirements and new builds. The EPA relies on a compilation of data from DOE EIA Form 860 (where facilities report their future retirement plans) and information included in the Agency's NEEDS database. This information is considered to be highly reliable, real-world information that provides the EPA with high confidence that such retirements will in fact occur. EPA plans to update this data on retirements and new builds at final rule using the latest information available from these sources at that time as well as input provided by commenter.

EPA's emissions budget methodology and formula for establishing Group 3 budgets are described in detail in the Ozone Transport Policy Analysis Proposed Rule TSD and summarized below.

a. Methodology for Determining Preset State Emissions Budgets for the 2023 and 2024 Control Periods

For determining state emissions budgets, the EPA generally uses historical ozone season data from the 2021 ozone season, the most recent data and therefore the most representative of near-term fleet conditions. This is similar to the approach taken in the CSAPR Update where the EPA began with 2015 data (the most recent year at the time). As in the CSAPR Update, the EPA combined historical data with IPM data to determine emissions budgets as follows:

(1) Determine a future year baseline—Start with the latest reported historical unit-level data (*e.g.,* 2021), and adjust any unit data where a retirement, a new build, a coal-to-gas conversion, or a SCR retrofit is known to occur by the baseline year. This results in a future year (*e.g.,* 2023) baseline for emissions budget purposes.

(2) Factor in additional emissions controls for the selected control stringency for the given state in the given year—For the unit-level emissions control technologies identified in this control stringency, adjust the baseline unit-level emissions and emissions rates. For example, if an SCR-controlled coal unit had a baseline emissions rate greater than 0.08 lb/mmBtu, its emissions rate and corresponding emissions would be adjusted down to levels reflecting its operation at 0.08 lb/mmBtu.

(3) Incorporate generation shifting—Use IPM in a relative way to capture the reductions expected from generation shifting (constrained to within each state) at the representative dollar per ton level corresponding to the selected control stringency.

By using historical unit and state-level NO_X emissions rates, heat input, and emissions data in the first stage of budget setting process outlined above, the EPA is grounding its budgets in the most recent representative historical operation for the covered units.[262] This dataset is a reasonable starting point for

[262] The EPA notes that historical state-level ozone season EGU NO_X emissions rates are publicly available and quality assured data. They are monitored using CEMS or other methodologies allowed for use by qualifying units under 40 CFR part 75 and are reported to the EPA directly by power sector sources.

the budget-setting process as it reflects the latest data reported by affected facilities under 40 CFR part 75. The reporting requirements include quality control measures, verification measures, and instrumentation to best record and report the data. In addition, the designated representatives of EGU sources are required to attest to the accuracy and completeness of the data. The EPA adjusted the 2021 ozone-season data to reflect committed fleet changes under a baseline scenario (*i.e.,* announced and confirmed retirements, new builds, and retrofits that have already occurred). For example, if a unit emitted in 2021, but retired in 2022, its 2021 emissions would not be included in the 2023 baseline estimate. For units that had no known changes, the 2023 baseline emissions assumption was the actual reported data from 2021. The EPA also included known new units and scheduled retrofits in this manner. Using this method, the EPA arrived at a baseline emission, heat input, and emissions rate estimate for each unit for a future year (*e.g.,* 2023), and then was able to aggregate those unit-level estimates to state-level totals. These state-level totals constituted the state's baseline from an engineering analytics perspective. The ozone-season state-level emissions, heat input, and emissions rates for covered sources under a baseline scenario were determined for each future year examined that receives a preset budget under this proposed rule (2023 and 2024).

The EPA then examined how the baseline emissions and emissions rates would change under different control stringencies for EGUs. For instance, under the SCR optimization scenario, if a unit was not operating its SCR at 0.08 lb/mmBtu or lower in the baseline, the EPA lowered that unit's assumed emissions rate to 0.08 lb/mmBtu and calculated the impact on the unit's and state's emissions rate and emissions. Note that the heat input is held constant for the unit in the process, reflecting the same level of unit operation compared to historical 2021 data. An improved emissions rate is then applied to this heat input, reflecting control optimization. In this manner, the state-level baseline totals reflecting known changes were adjusted to reflect the additional application of the assumed control technology at a given control stringency.

Finally, the EPA used IPM to capture any generation shifting at a given control stringency necessary for the majority of the respective emissions control technology to operate. The EPA explains how it accounts for generation shifting in more detail in Section VI.B of this proposed rule and in the Ozone Transport Policy Analysis Proposed Rule TSD. In this rule, as a proxy for the near-term reductions required in 2023 and 2024, the EPA has constrained generation shifting to occur only within-state. The EPA also estimates emissions reductions associated with generation shifting in 2025 and 2026 for purposes of the illustrative state budgets, but as explained below, the dynamic budget process to determine budgets for those years will incorporate emissions reductions attributable to generation shifting through the inclusion of newly reported unit-level data from the future compliance periods.

b. Methodology for Determining Dynamic State Emissions Budgets for Control Periods in 2025 Onwards

The methodology for determining state emissions budgets for later control periods (2025 and beyond) is nearly identical to the process for quantifying preset budgets in 2023 and 2024 described earlier; it is just applied at a later date and applied to the most recent representative operational available at that time. The EPA will issue by ministerial action these dynamic budget quantifications approximately 1 year before the relevant control period. For instance, starting in early 2024, the EPA would take the most recent 2023 ozone season data, calculate 2025 state emissions budgets using the methodology below and update its unit-level and state-level state emissions budget files that will be released when this rule is finalized (and for which the EPA has included in this proposed rule current examples for public comment). By March 1 of 2024, and each year thereafter, the EPA would make publicly available (in manner similar to data and preliminary computations for allocations from new unit set-asides) the preliminary state emissions budgets and unit-level allocations for the subsequent control period (*e.g.,* 2025) and would provide stakeholders with a 30-day opportunity to submit any objections to the updated data and computations. By May 1 of 2024, and each year thereafter, the EPA would issue the final budgets and allowance allocations for the next control period (*e.g.,* 2025).

The differences to each of the formula steps to calculate dynamic budgets for control periods in 2025 and beyond, relative to the calculation of preset budgets for the 2023 and 2024 control periods, are described later:

(1) Determine a future year baseline—At this step, the EPA would start with the latest reported historical unit-level heat input data available at that time (*e.g.,* for 2025 state emissions budgets, the EPA would use the newly available 2023 heat input data rather than 2021 heat input data). Doing so would capture the latest operational data reflecting new builds and retirements. This would yield a future year (*e.g.,* 2025) baseline for emissions budget purposes.

(2) Factor in additional emissions controls for the selected control stringency for the given state in the given year—For the unit-level emissions reduction measures identified in the selected control stringency, adjust the baseline unit-level emissions and emissions rates. This step would be nearly the same for control periods in 2025 and beyond as for the 2023 and 2024 control periods, the only difference being that as described in Section VI.D of this proposed rule, for each control period from 2026 onward, the unit-specific emissions rates assumed for all affected states except Alabama, Delaware, and Tennessee will reflect the selected control stringency that incorporates post-combustion control retrofit opportunities for the relevant units identified in the state emissions budgets and calculations appendix to the Ozone Transport Policy Analysis Proposed Rule TSD. These rates would be defined in this rule and would not change subsequently. They would not be applied until 2026, based on the time necessary to install these mitigation technologies as discussed in Sections VI.B, VI.C, and VII.A of this proposed rule.

(3) Incorporate generation shifting—This step would be automatically captured in dynamic budget calculations as generation shifting in a compliance scenario would no longer have to be projected by IPM and incorporated into the state budgets through an additional calculation. Instead, it would be embodied in the newly reported heat input data described above and that is used to determine the dynamic budgets.

Additional details, corresponding data and formulas, and examples for the dynamic budget are described in the Ozone Transport Policy Analysis Proposed Rule TSD.

c. Proposed and Illustrative State Emissions Budgets

For each covered state (and Indian country within the state's borders), preset budgets are established for the two individual control periods 2023 and 2024. For 2025 and beyond, the dynamic budget formula promulgated in this proposed rule would be applied to future year data to quantify state emissions budgets for those control periods. The proposed default procedures for allocating the allowances from each state budget among the units in each state (and Indian country within the state's borders) are described in Section VII.B.9 of this proposed rule. The amounts of the proposed state emissions budgets for the 2023 and 2024 control periods are shown in Table VII.B.4.c–1. Table VII.B.4.c–2 shows illustrative state emissions budgets for the 2025 and 2026 control periods derived by applying the identified control stringency to the most recent historical data, but these budgets are only illustrative because, under the proposal, the implemented state emissions budgets for these years will be determined at a future date through application of the proposed budget-setting methodology to data that reflect the emissions control stringencies finalized in the rulemaking combined with the latest available data on the composition and utilization of the EGU fleet.

TABLE VII.B.4.C–1—PROPOSED CSAPR NO_X OZONE SEASON GROUP 3 STATE EMISSIONS BUDGETS FOR THE 2023 AND 2024 CONTROL PERIODS [a b]

State	Proposed emissions budgets for 2023 control period (tons)	Proposed emissions budgets for 2024 control period (tons)
Alabama	6,364	6,306
Arkansas	8,889	8,889
Delaware	384	434
Illinois	7,364	7,463
Indiana	11,151	9,391
Kentucky	11,640	11,640
Louisiana	9,312	9,312
Maryland	1,187	1,187
Michigan	10,718	10,718
Minnesota	3,921	3,921
Mississippi	5,024	4,400
Missouri	11,857	11,857
Nevada	2,280	2,372
New Jersey	799	799
New York	3,763	3,763
Ohio	8,369	8,369
Oklahoma	10,265	9,573
Pennsylvania	8,855	8,855
Tennessee	4,234	4,234
Texas	38,284	38,284
Utah	14,981	15,146
Virginia	3,090	2,814
West Virginia	12,478	12,478
Wisconsin	5,963	5,057
Wyoming	9,125	8,573

Table Notes:

[a] The state emissions budget calculations pertaining to Tables VII.B.4.c–1 and VII.B.4.c–2 are described in greater detail in the Ozone Transport Policy Analysis Proposed Rule TSD. Budget calculations and underlying data are also available in Appendix A of that TSD.

[b] In the event a final rule in this rulemaking becomes effective after May 1, 2023, the emissions budgets and assurance levels for the 2023 control period would be adjusted under the rule's proposed transitional provisions to ensure that the increased stringency of the new budgets would apply only after the rule's effective date, even though the revised Group 3 trading program would be implemented for most sources as of the start of the 2023 ozone season on May 1, 2023. The 2023 budget amounts shown in Table VII.B.4.c–1 do not reflect these possible adjustments. The transitional provisions are discussed in Section VII.B.11 of this proposed rule.

TABLE VII.B.4.C–2—ILLUSTRATIVE CSAPR NO_X OZONE SEASON GROUP 3 STATE EMISSIONS BUDGETS FOR THE 2025 AND 2026 CONTROL PERIODS

State	Illustrative emissions budgets for 2025 control period (tons)	Illustrative emissions budgets for 2026 control period (tons)
Alabama	6,306	6,306
Arkansas	8,889	3,923
Delaware	434	434
Illinois	7,463	6,115
Indiana	8,714	7,791
Kentucky	11,134	7,573
Louisiana	9,179	3,752

5. Variability Limits and Assurance Levels

Like each of the other CSAPR trading programs, the Group 3 trading program currently includes assurance provisions designed to limit the total emissions from the sources in each state (and Indian country within the state's borders) in each control period to an amount close to the state's emissions budget for the control period, consistent with the good neighbor provision's requirement that required emissions reductions must be achieved within the state, while allowing some flexibility beyond the emissions budget to accommodate year-to-year operational variability beyond sources' reasonable ability to control. For each state, the assurance provisions establish an assurance level for each control period, defined as the sum of the state's emissions budget for the control period plus a variability limit, which under the existing Group 3 trading program regulations is 21 percent of the relevant state emissions budget. The purpose of the variability limit is to account for year-to-year variability in EGU operations, which can occur for a variety of reasons including changes in weather patterns, changes in electricity demand, and disruptions in electricity supply from other units or from the transmission grid. Because of the need to account for such variability in operations of each state's EGUs, the fact that emissions from the state's EGUs may exceed the state's emissions budget for a given control period is not treated as inconsistent with satisfaction of the state's good neighbor obligations as long as the total emissions from the EGUs remain below the state's assurance level. Emissions from a state's EGUs above the state's emissions budget but below the state's assurance level are treated in the same manner as emissions below the state's emissions budget in that such emissions are subject to the same requirement to surrender allowances at a ratio of one allowance per ton of emissions. In contrast, emissions above the state's assurance level for a given control period are strongly discouraged as inconsistent with the state's good neighbor obligations and are subject to an overall 3-for-1 allowance surrender ratio. The establishment of assurance levels with associated extra allowance surrender requirements was intended to respond to the D.C. Circuit's holding in *North Carolina* requiring the EPA to ensure within the context of an interstate trading program that sources in each state are required to address their good neighbor obligations within the state and may not simply shift those obligations to other states by failing to reduce their own emissions and instead surrendering surplus allowances purchased from sources in other states.[263]

In this rulemaking, the EPA is not proposing to alter the basic structure of the Group 3 trading program's assurance provisions, which would continue to set an assurance level for each control period equal to the state's emissions budget for the control period plus a variability limit and would continue to apply a 3-for-1 surrender ratio to emissions exceeding the state's assurance level.[264] Each assurance level also would continue to apply to the collective emissions of all units within the state and Indian country within the state's borders.[265] For the 2023 and 2024 control periods, the EPA proposes to retain the Revised CSAPR Update's methodology for determining each state's variability limit as 21 percent of the state's emissions budget for the control period, except that because the EPA is proposing to revise the state emissions budgets for these control periods, the EPA proposes to determine the corresponding variability limits as 21 percent of the revised budgets. However, for control periods after 2024, the EPA is proposing a change to the methodology for determining the variability limits. Specifically, the EPA proposes to determine each state's variability limit for the control periods in 2025 or a later year so that, instead of always multiplying the state's emissions budget for the control period by a value of 21 percent, the percentage value used would be the higher of 21 percent or the percentage (if any) by which the total reported heat input of the state's affected EGUs in the control period exceeds the total reported heat input of the state's affected EGUs as reflected in the state's emissions budget for the control period. For example, if the total reported heat input of the state's covered sources for the 2025 control period was 90 percent or 110 percent of the total reported heat input of the state's covered sources for the 2023 control period (*i.e.,* the heat input the EPA would have used in computing the state's 2025 emissions budget), then the state's variability limit for the 2025 control period would be 21 percent of the state's emissions budget, while if the total reported heat input of the state's covered sources for the 2025 control period was 130 percent of the total reported heat input of the state's covered sources for the 2023 control period, then the state's variability limit for the 2025 control period would be 30 percent of the state's emissions budget. The EPA expects that the minimum 21 percent would apply in almost all instances, and that the alternative, higher percentage value would apply only in control periods where operational variability caused an extreme increase relative to the earlier year used in setting the state's emissions budget, which would be a situation

[263] 531 F.3d at 908.

[264] As discussed in Section VII.B.8 of this proposed rule, the EPA is also proposing to establish a new secondary emissions limitation for individual units that would apply in situations where an exceedance of the relevant state's assurance level has occurred.

[265] *See* 40 CFR 97.1002 (definitions of ''common designated representative,'' ''common designated representative's assurance level'' and ''common designated representative's share''), 97.1006(c)(2), and 97.1025.

meriting a temporarily higher variability limit and assurance level.

The purpose of the proposed revision to the variability limits is to better align the variability limits for successive control periods with the regularly updated heat input data that would be used in the proposed process for dynamically setting the state emissions budgets. Under EPA's proposed budget-setting process, each emissions budget would be computed using the latest available reported heat input, which for each budget set for a control period in 2025 or a later year would be the heat input for the control period two years before the control period whose budget is being determined (for example, the state emissions budgets for the 2025 control period would be computed in early 2024 using the reported heat input for the 2023 control period). The proposed revised variability limits would be well coordinated with the budgets established using this dynamic budgeting process, because the percentage change in the actual heat input for the control period relative to the earlier-year heat input used in computing the state's emissions budget would be an appropriate measure of the degree of operational variability actually experienced by the state's EGUs in the control period relative to the assumed operating conditions reflected in the state's budget. Setting a variability limit in this manner would be entirely consistent with the overall purpose of including variability limits in the assurance provisions.

The reason the EPA is proposing to use the higher of a fixed 21% or the percentage change in heat input computed as just described is that the EPA believes that, for operational planning purposes, it can be useful for sources to know in advance of the control period a minimum value for what the variability limit could turn out to be. Because a state's actual total heat input for a control period is not known until after the end of the control period, this proposed revision would have the consequence that the state's final variability limit and assurance level for the control period also would not be known until after the control period. However, because the proposed rule provides that the variability limit would always be at least 21 percent, the sources in a state would be able to rely for planning purposes on the knowledge that the assurance level would always be at least 121 percent of the state's emissions budget for the control period. Advance knowledge of the minimum possible amount of the assurance level can be useful to sources, because one way a source can be confident that it will never incur the 3-for-1 allowance surrender ratio owed for emissions exceeding its state's assurance level is to plan its operations so as to never allow its own emissions to exceed its own share of the state's assurance level for the control period. Knowing that the variability limit would always be at least 21 percent would provide sources with values they could use for such planning purposes.

The EPA believes that 21 percent is a reasonable value to use as the fixed variability limit for the 2023 and 2024 control periods and as the minimum variability limit for the control periods in 2025 and later years. To determine appropriate variability limits for the trading programs established in CSAPR, the EPA analyzed historical state-level heat input variability over the period from 2000 through 2010 as a proxy for emissions variability, assuming constant emissions rates. *See* 76 FR 48265. Based on that analysis, the variability limits for ozone season NO_X in both CSAPR and the CSAPR Update were set at 21 percent of each state's budget, and these variability limits for the NO_X ozone season trading programs were then codified in 40 CFR 97.510 and 40 CFR 97.810, along with the respective state budgets. For the Revised CSAPR Update, the EPA performed an updated variability analysis for the twelve states being moved into the Group 3 trading program in that rulemaking, evaluating historical state-level heat input variability over the period from 2000 through 2019. The updated analysis again resulted in a variability estimate of 21 percent. The EPA also considered shorter time periods for the updated analysis and found that the resulting variability estimates were not especially sensitive to the particular time period analyzed.[266] A further updated analysis for this rulemaking again results in a variability estimate of 21 percent for most states, and although the historical analysis indicates higher percentages for the two states with the smallest total heat input figures in this analysis—Delaware and New Jersey—the EPA does not consider it appropriate to raise the variability limit percentage beyond 21 percent for all other states based on the analytic results for these states, where small absolute heat input figures have resulted in larger variability percentages.[267] Based on the consistent conclusions of these multiple analyses, the EPA proposes to continue using 21 percent as the fixed variability limit percentage for the 2023 and 2024 control periods and as the minimum value in the revised approach for establishing variability limits for the control periods in 2025 and later years.

The EPA requests comment on the proposed rule to set variability limits for the 2023 and 2024 control periods as 21 percent of the respective revised state emissions budgets, consistent with the methodology used to determine the variability limits for these control periods set in the Revised CSAPR Update. In addition, the EPA requests comment on whether to set higher variability limits for Delaware and New Jersey for 2023 and 2024 based on the results of the most recent variability analysis. The EPA also requests comment on the proposed rule to establish a revised methodology for setting variability limits for all states for control periods in 2025 and later years, as discussed in this section.

6. Annual Recalibration of Allowance Bank

As discussed in Section VII.B.1.b of this proposed rule, in this rulemaking, the EPA is proposing two revisions to the Group 3 trading program designed to better maintain the control stringency selected in the final rule in this rulemaking. The first proposed revision, discussed Section VII.B.4 of this proposed rule, is to adopt a dynamic budget-setting methodology that would allow state emissions budgets in future years to reflect more accurate information about the composition and utilization of the EGU fleet. The second, complementary, proposed revision is to recalibrate the bank of unused allowances each control period in order to prevent allowance surpluses in individual control periods from accumulating and adversely impacting the ability of the trading program in future control periods to maintain the selected control stringency identified in the rulemaking as necessary to address states' good neighbor obligations with respect to the 2015 ozone NAAQS.

The EPA proposes to begin the bank recalibration process starting with the 2024 control period, after the compliance process for the 2023 control period for all current and newly added states in the Group 3 trading program

[266] For details on the original variability analysis for 26 states over the 2000–2010 period, including a description of the methodology, see the Power Sector Variability Final Rule TSD from the CSAPR (EPA–HQ–OAR–2009–0491–4454). For the updated variability analysis for twelve states for the 2000–2019 period, *see* the Excel file ''Historical Variability in Heat Input 2000 to 2019.xls.'' Both documents are available in the docket for this proposal.

[267] *See* the Excel document, ''OS Heat Input Variability 2000 to 2021.xls'' for updated data, application of the CSAPR variability methodology, and results applied to heat input for 2000 through 2021 for all states and for the region collectively.

has been completed. The recalibration process for each control period would be carried out on or shortly after August 1 of that control period, two months after the compliance deadline for the previous control period, making the proposed date of the first recalibration August 1, 2024. The recalibrations could not take place significantly earlier than August 1 each year because compliance for the previous control period would not be completed until after June 1. However, because data on the amounts of allowances held are publicly available and the total quantity of allowances needed for compliance for the previous control period would be known shortly after the end of that control period, sources and other market participants would be able to ascertain with reasonable accuracy shortly after the end of each control period what degree of recalibration to expect for the next control period, even if the recalibration would not actually be carried out until the following August.

Before undertaking a recalibration process each control period, the EPA would first determine whether the total amount of all banked Group 3 allowances from previous control periods held in all facility accounts and general accounts in the Allowance Management System accounts exceeds the target bank amount. (For this purpose, no distinction would be made between banked Group 3 allowances issued from the state emissions budgets for previous control periods and banked Group 3 allowances issued through the conversion of previously banked Group 2 allowances.) If the total amount of banked Group 3 allowances does not exceed the target bank amount, the EPA would not carry out any recalibration for that control period. If the total amount of unused allowances does exceed the target bank amount, the EPA would determine for each account with holdings of banked Group 3 allowances the account-specific recalibrated amount of allowances, computed as the target bank amount multiplied by the account's total holdings of banked Group 3 allowances and divided by the total amount of banked Group 3 allowances in all accounts, rounded up to the nearest allowance. Finally, the EPA would deduct from each account any banked Group 3 allowances exceeding the account's recalibrated amount of banked allowances.

As the target bank amount used in the recalibration process for each control period, the EPA proposes to use an amount determined as 10.5 percent of the sum of the state emissions budgets for the control period, or half of the sum of the states' proposed minimum variability limits. The EPA has two reasons for proposing this amount. First, in the transition from CSAPR to the CSAPR Update, where the EPA set a target bank amount 1.5 times the sum of the variability limits, and in the transition from the CSAPR Update to the Revised CSAPR Update, where the EPA set a target bank amount of 1.0 times the sum of the variability limits, in each case the initial bank proved larger than necessary, as total emissions of all sources in the program were less than the budgets. Second, an analysis of year-to-year variability of heat input for the region covered by this proposed rule suggests that the regional heat input for an individual year can be expected to vary by up to 10.5 percent above or below the central trend with 95% confidence. This variability analysis is an application to the entire region of the variability analysis EPA has performed for individual states to establish the variability limit of 21 percent for the states in the trading program.[268] When the analysis is performed at the regional level, the data show less year-to-year variation than when the analysis is performed at the individual state level. Within the trading program structure, it is logical to use variability analyzed at the level of individual states to set the variability limits, which apply at the level of individual states, while using variability analyzed at the level of the overall region to set a target level for a bank, which will apply at the level of the overall program.

The annual bank recalibrations will help maintain the control stringency determined to be necessary to address states' good neighbor obligations for the 2015 ozone NAAQS. Moreover, the proposed recalibrations are less complex than alternative approaches would be. For example, the NO_X Budget Trading Program established in the NO_X SIP Call also contained provisions designed to prevent excessive accumulations of banked allowances on program stringency, but those provisions—under the name ''progressive flow control''—introduced uncertainty as to whether banked allowances would be usable to offset one ton of emissions or less than one ton of emissions in the current control period. The EPA considers the recalibration mechanism proposed here to be simpler with less associated uncertainty.

Finally, the EPA observes that the proposed recalibration mechanism is entirely consistent with the Agency's existing authority under 40 CFR 97.1006(c)(6) to ''terminate or limit the use and duration'' of any Group 3 allowance ''to the extent the Administrator determines is necessary or appropriate to implement any provision of the Clean Air Act.'' The Administrator proposes to determine that the recalibrations are both necessary and appropriate to ensure that the control stringency selected in this rulemaking is maintained and states' good neighbor obligations with respect to the 2015 ozone NAAQS are addressed.

The EPA requests comment on the proposed bank recalibration provisions and the proposed use of a target bank amount computed as 10.5 percent times the sum of the state emissions budgets for each control period.

7. Unit-Specific Backstop Daily Emissions Rates

While the identified EGU emissions reductions in Section VI of this proposed rule are incentivized and secured primarily through the corresponding seasonal state emissions budgets (expressed as a seasonal tonnage limit for all covered EGUs within a state's borders) described earlier, the EPA is also incorporating backstop daily emissions rates of 0.14 lb/mmBtu for coal-fired steam units serving generators with nameplate capacity greater than or equal to 100 MW in covered states. The backstop emissions rates will first apply in 2024 for coal-fired steam units with existing SCR controls, and in 2027 for coal-fired steam units currently without SCR controls. For a unit that exceeds its applicable backstop daily emissions rate on any day, all emissions on that day exceeding the emissions that would have occurred at the backstop daily emissions rate will be subject to a 3-for-1 allowance surrender ratio instead of the normal 1-for-1 allowance surrender ratio. See Appendix A of the Ozone Transport Policy Proposed Rule TSD for a list of coal-fired steam units serving generators larger than or equal to 100 MW in covered states for which the identified backstop emissions rate would apply starting in either 2024 or 2027.

The EGU NO_X Mitigation Strategies Proposed Rule TSD describes the methodology for deriving the 0.14 lb/mmBtu daily rate limit in more detail. The methodology is summarized as follows. First, consistent with

[268] See the Power Sector Variability Final Rule TSD from CSAPR, available at *https://www.epa.gov/csapr/power-sector-variability-final-rule-tsd for a description of the methodology.* Also see the Excel document ''OS Heat Input—Variability 2000 to 2021.xls'' for updated data, application of the CSAPR variability methodology, and results applied to heat input for 2000 through 2021 for all states and for the region collectively.

stakeholders' focus on providing daily assurance of control operation, EPA determined that daily (as opposed to hourly or monthly) was an appropriate time metric for backstop emissions rate limits instituted to ensure operation of controls on high ozone days. The EPA derived the 0.14 lb/mmBtu daily rate limit by determining the particular level of a daily rate that would be comparable in stringency to the 0.08 lb/mmBtu seasonal emissions rate that the Agency has identified as reflecting SCR optimization at existing units.[269] The EPA first conducted an empirical exercise using reported daily emissions rate data from existing, SCR-controlled coal units that were emitting at or below 0.08 lb/mmBtu on a seasonal average basis. Recognizing that this seasonal rate reflects the average across a unit's range of varying daily rates reflecting different operation conditions, including some occasions when the SCR control may not be operating or may not be fully optimized, the EPA identified the upper end of the daily emissions rate range for these units. When the EPA examined the daily emissions rate pattern for these units considered to be optimizing their SCRs on a seasonal basis, the EPA observed that over 95 percent of the time, their daily rates were below 0.14 lb/mmBtu. In addition, for these units, less than 1 percent of their seasonal emissions would exceed this daily rate limit.

The EPA conducted this analysis to be consistent with the methodology developed in the 2014 1-hr SO_2 attainment area guidance for identifying ''comparably stringent'' emissions rates over varying time-periods.[270] Appendix C of that guidance describes a series of steps that involve: (1) Compiling emissions data to reflect a distribution of emissions rates with various averaging times, (2) determining the 99th percentile of the average emissions values compiled in the previous step, and then (3) applying ''adjustment factors'' or ratios of the 99th percentile values to emissions rates to convert them (usually from a short-term rate to a longer-term rate). In this case, the EPA applied the methodology in reverse to convert a longer-term limit (the seasonal rate of 0.08 lb/mmBtu which was assumed to be equal to a 30-day rate of 0.08 lb/mmBtu) to a comparably stringent short-term limit (a daily rate of 0.14 lb/mmBtu). The EPA requests comment on the proposed incorporation of a backstop daily emissions rate element into the Group 3 trading program and on the proposed methodology for determining the daily emissions rate of 0.14 lb/mmBtu.

In addition, the EPA requests comment on application of the backstop daily emissions rates in the event that an affected unit finds it more economic to retire shortly after the start of the 2027 ozone season in lieu of investing in new NO_X post-combustion control technology. This proposed rule's state emissions budgets would require emissions reductions starting in 2026 commensurate with SCR retrofits at these units regardless of when these unit-level backstop rates are subsequently imposed. The EPA recognizes that such retrofits in practice may be less environmentally efficient compared to imminent retirement that would potentially yield lower cumulative emissions of NO_X and multiple other pollutants over time. The EPA also recognizes that several coal-fired EGUs have been considering retirement by 2028 under compliance pathways available under Clean Water Act effluent guidelines[271] and the coal combustion residuals rule under the Resource Conservation and Recovery Act.[272] 2028 also represents the end of the second planning period under the Regional Haze program, and thus is a significant year in states' planning of strategies to make reasonable progress towards natural visibility at Class I areas.[273] To facilitate a potentially economic and environmentally superior unit-level compliance response across these programs that nonetheless maintains the NO_X reductions required by the state budgets from 2026 forward in this proposed rule, the EPA is requesting comment on potentially deferring the application of the backstop daily rate for large coal EGUs that submit written attestation to the EPA that they make an enforceable commitment to retire by no later than the end of calendar year 2028. EPA anticipates that units failing to retire contrary to their attestation would become subject to the backstop emissions rate in the 2029 ozone season, and would likely be subject to other appropriate enforcement proposed rule under the Clean Air Act or other relevant authorities.

8. Unit-Specific Emissions Limitations Contingent on Assurance Level Exceedances

As emphasized by the D.C. Circuit in its decision invalidating CAIR, under the CAA's good neighbor provision, emissions ''within the State'' that contribute significantly to nonattainment or interfere with maintenance of a NAAQS in another state must be prohibited. *North Carolina* v. *EPA,* 531 F.3d 896, 906–908 (D.C. Cir. 2008). The CAIR trading programs contained no provisions limiting the degree to which a state could rely on net purchased allowances as a substitute for making in-state emissions reductions, an omission which the court found was inconsistent with the requirements of the good neighbor provision. *Id.* In response to that holding, the EPA established the CSAPR trading programs' assurance provisions to ensure that, in the context of a flexible trading program, the emissions reductions required under the good neighbor provision in fact will take place within the state. The EPA believes the assurance provisions have generally been successful in achieving that objective, as evidenced by the fact that since the assurance provisions took effect in 2017, out of the nearly 300 instances where a given state's compliance with the assurance provisions of a given CSAPR trading program for a given control period has been assessed, a state's collective emissions have exceeded the applicable assurance level only four times.

Unfortunately, the EPA also recognizes that the assurance provisions' very good historical compliance record is not good enough. The four past exceedances all occurred under the Group 2 trading program: Sources in Mississippi collectively exceeded their applicable assurance levels in the 2019 and 2020 control periods, and sources in Missouri collectively exceeded their applicable assurance levels in the 2020 and 2021 control periods.[274] Both of the

[269] *See* page 24 of ''Guidance for 1-hour SO_2 Nonattainment Area SIP Submission'' at *https://www.epa.gov/sites/default/files/2016-06/documents/20140423guidance_nonattainment_sip.pdf.* ''A limit based on the 30-day average of emissions, for example, at a particular level is likely to be a less stringent limit than a 1-hour limit at the same level 1 since the control level needed to meet a 1-hour limit every hour is likely to be greater than the control level needed to achieve the same limit on a 30-day average basis.''

[270] *See* Guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions available at *https://www.epa.gov/sites/default/files/2016-06/documents/20140423guidance_nonattainment_sip.pdf.*

[271] *See* 40 CFR 423.11(w).

[272] *See* 40 CFR 257.103(b).

[273] *See* 40 CFR 51.308(f).

[274] Information on the assurance level exceedances in the 2019 and 2020 control periods is available in the final notices concerning EPA's administration of the assurance provisions for those control periods. 85 FR 53364 (August 28, 2020); 86 FR 52674 (September 22, 2021). The EPA will publish an analogous final notice for the 2021 control period by October 1, 2022, and will also publish a preliminary notice by August 1, 2022. At this time, information on the relevant Missouri assurance level for the 2021 control period is available at 40 CFR 97.806(c)(2) and 97.810 and preliminary data on Missouri units' emissions of

exceedances by Missouri sources could easily have been avoided if the owner and operator of several SCR-equipped, coal-fired steam units had not chosen to idle the units' controls and rely instead on net out-of-state purchased allowances. The exceedances were large, and ample quantities of allowances to cover the resulting 3-for-1 allowance surrender requirements were purchased in advance, suggesting that the assurance level exceedances may have been anticipated as a possibility. In the case of the Mississippi exceedances, the exceedances were smaller, operational variability (manifesting as increased heat input) appears to have been a material contributing factor, and the EPA has not concluded that the owners and operators anticipated the exceedances. However, an additional contributing factor was the fact that several large, gas-fired steam units without SCR controls emitted NO_X at average rates much higher than the average emissions rates the same units had achieved in previous control periods. In short, while the Missouri exceedances appear far more significant, EPA's analysis indicates that all four past exceedances could have been avoided if the units most responsible had achieved emissions rates more comparable to the same units' previous performance. In EPA's view, the operation of the Missouri units in particular—although not prohibited by the current regulatory requirements—cannot be reconciled with the statutory requirements of the good neighbor provision. The fact that such operation is not prohibited by the current regulations therefore indicates a deficiency in the current regulatory requirements.

To correct the deficiency in the regulatory requirements, the EPA proposes in this rulemaking to revise the Group 3 trading program regulations to establish an additional emissions limitation to more effectively deter avoidable assurance level exceedances. Because the pollutant involved is ozone season NO_X and the particular sources for which deterrence is most needed are located in states that are proposed to transition soon from the Group 2 trading program to the Group 3 trading program, the EPA is proposing to promulgate the strengthening provisions as revisions to the Group 3 trading program regulations rather than the Group 2 trading program regulations.[275]

The two current emissions-related compliance requirements in the Group 3 trading program regulations are both structured in the form of requirements to hold allowances. The first requirement applies at the source level: Specifically, at the compliance deadline after each control period, the owners and operators of each source covered by the program must surrender a quantity of allowances that is determined based on the emissions from the units at the source during the control period. The second requirement applies at the designated representative level (which typically is the owner or operator level): If the state's sources collectively emit in excess of the state's assurance level, the owners and operators of each set of sources determined to have contributed to the exceedance must surrender an additional quantity of allowances. As long as a source's owners and operators comply with these two allowance surrender requirements (and meet certain other requirements not related to the amounts of the sources' emissions), they are in compliance with the program.

In light of the operation of the Missouri sources, the EPA is doubtful that strengthening the assurance provisions by increasing allowance surrender requirements at the unit, source, or designated representative level would create a sufficient deterrent. Accordingly, the EPA is proposing instead to add a new, unit-level emissions limitation structured as a prohibition to emit NO_X in excess of a defined amount. A violation of the prohibition would not trigger additional allowance surrender requirements beyond the surrender requirements that would otherwise apply, but would trigger the possible application of the CAA's enforcement authorities. Because the purpose of the new unit-level emissions limitation would be to deter conduct causing exceedances of a state's assurance level, the EPA proposes to condition applicability of the new limitation on (1) the occurrence of an exceedance of the state's assurance level for the control period, and (2) the apportionment of at least some of the responsibility for the assurance level exceedance to the set of units represented by the unit's designated representative. Apportionment of responsibility for the assurance level exceedance would be carried out according to the existing assurance provision procedures and would therefore depend on the designated representative's shares of both the state's total emissions for the control period and the state's assurance level for the control period. The new emissions limitation would be in addition to, not in lieu of, the other requirements of the Group 3 trading program. This point would be made explicit by relabeling the source-level allowance holding requirement, currently called the "emissions limitation," as the "primary emissions limitation" and labeling the new unit-level requirement as the "secondary emissions limitation." (The regulations label the designated representative-level requirement as "compliance with the . . . assurance provisions.")

The EPA proposes to define the unit-level secondary emissions limitation by formula to reflect the amount of additional NO_X emissions caused by the unit's deviation from a benchmark seasonal average NO_X emissions rate during the control period, where the benchmark seasonal average NO_X emissions rate for the unit would be based on emissions rates the unit has achieved in the past plus a 25 percent margin. The EPA also proposes to use a floor for past performance of 0.08 lb/mmBtu (yielding 0.10 lb/mmBtu when the 25 percent margin is added), exclude control periods where the unit operated in less than 10 percent of the hours (in order to avoid data that might be unrepresentative), and screen out instances where the amount of additional emissions caused by the poor performance is less than 50 tons. Specifically:

- The EPA proposes to define a unit's secondary emissions limitation for a control period, in tons of NO_X, as the sum of 50 tons plus the product of (1) the unit's benchmark seasonal average emissions rate times (2) the unit's actual heat input for the control period, except that if the unit operated during less than 10 percent of the hours in the control period, no secondary emissions limitation would be defined for the unit for that control period.
- The EPA proposes to calculate the benchmark seasonal average NO_X

NO_X during the 2021 ozone season are available at *ampd.epa.gov.*

275 The EPA believes that the occurrence of avoidable assurance level exceedances under the Group 2 trading program, combined with the express statutory directive that good neighbor obligations must be addressed "within the state," and through "prohibition," would also provide a sufficient legal basis for the Agency to promulgate the same revisions to the assurance provisions for all the other CSAPR trading programs. The EPA is not proposing to do so at this time because the Agency has seen no reason to expect exceedances of the assurance levels under any of the other CSAPR trading programs by any of the states that will remain subject to the respective trading programs after this rulemaking, except possibly by Missouri under the CSAPR NO_X Annual Trading Program. The EPA expects that reductions in Missouri's seasonal NO_X emissions sufficient to comply with the proposed provisions of the revised Group 3 trading program, including the secondary emissions limitations, would also prevent exceedances of Missouri's currently applicable assurance level for annual NO_X emissions.

emissions rate for a unit for this purpose, in lb NO_X/mmBtu, as the higher of (1) 0.10 lb/mmBtu or (2) 125 percent of the unit's lowest seasonal average NO_X emissions rate in a previous control period under the CSAPR NO_X Ozone Season Group 1, Group 2, or Group 3 Trading Program, excluding any control periods where the unit operated for less than 10 percent of the hours in the ozone season.[276]

Table VII.B.8–1 shows the secondary emissions limitations that the proposed formula would have produced and which units would have exceeded those limitations if the limitations and formula had been in effect for the Group 2 trading program in 2019, 2020, and 2021 when assurance level exceedances occurred in Mississippi and Missouri. The EPA believes that in each case the formula functions in a reasonable manner, and the units identified as exceeding their respective secondary emissions limitations are sources for which an enforcement deterrent under CAA sections 113 and 304 would have been appropriate to compel better control of NO_X emissions.

TABLE VII.B.8–1—ILLUSTRATIVE RESULTS OF APPLYING PROPOSED SECONDARY EMISSIONS LIMITATION IN PREVIOUS INSTANCES OF ASSURANCE LEVEL EXCEEDANCES

Owner/operator	Unit	Benchmark NO_X emissions rate (lb/mmBtu)	Actual NO_X emissions rate (lb/mmBtu)	Secondary emissions limitation (tons)	Actual NO_X emissions (tons)	Exceedance (tons)

For further illustrations of the application of the proposed formula and secondary emissions limitation to other units in the states proposed to be subject to the expanded Group 3 trading program in the control periods from 2016 through 2021, see the spreadsheet ''Illustrative Calculations Using Proposed Secondary Emissions Limitation Formula'', available in the docket. The EPA notes that, with the exception of the units listed in Table VII.B.8–1, no unit shown in the spreadsheet as having emissions exceeding the illustrative secondary emissions limitation calculated for the unit would have violated the proposed prohibition because no violation would occur in the absence of an exceedance of the assurance level and apportionment of responsibility for a share of the exceedance to the unit under the assurance provisions.

The EPA requests comment on the proposal to establish a secondary emissions limitation for the Group 3 trading program as described in this section. The EPA specifically requests comment on the proposed form of the secondary emissions limitation, the proposed formula for computing each unit's secondary emissions limitation, and the proposed values for the screening parameters used in the calculations.

9. Unit-Level Allowance Allocation and Recordation Procedures

In the Revised CSAPR Update, the EPA established default procedures for allocating CSAPR NO_X Ozone Season Group 3 allowances (''Group 3 allowances'') in amounts equal to each state emissions budget for each control period among the sources in the state for use in complying with the Group 3 trading program. The EPA also provided states with several options to submit SIP revisions which, if approved, would result in the replacement of EPA's allowance allocations with state-determined allowance allocations for the 2022 control period and beyond. The current regulations (*i.e.,* before this proposed rule) provide that EPA's allocations and allocation procedures apply for the 2021 control period and, by default, for subsequent control periods unless and until a state provides state-determined allowance allocations under an approved SIP revision.

The current default allocation process for the Group 3 trading program established in the Revised CSAPR Update involves three main steps. First, a portion of each state emissions budget for each control period is reserved for potential allocation to units that are subject to allowance holding requirements and that would not otherwise receive allowance allocations in the overall allocation process. Under the current Group 3 trading programs, the reserved allowances are made available generally (but not exclusively[277]) to ''new'' units—which for purposes of the Revised CSAPR Update means units commencing commercial operation on or after January 1, 2019—through a ''new unit set-aside'' established for qualifying units in each state and, if areas of Indian country exist within the state's borders, a separate ''Indian country new unit set-

[276] In proposing a formulation for a benchmark rate for the specific regulatory purpose of defining a secondary emissions limitation under the Group 3 trading program, the EPA is not expressing a view that the same formulation of a benchmark rate would be suitable for any other regulatory purpose.

[277] The units qualifying for allocations from a new unit set-aside may include not only units that have recently started operating but also units that previously received, but are no longer eligible to receive, allocations from the unreserved portion of the budget as ''existing'' units.

aside'' for qualifying units in such Indian country. Second, in advance of each control period, the unreserved portion of the state budget is allocated among the state's eligible ''existing'' units—which for purposes of the Revised CSAPR Update generally means units that commenced commercial operation before January 1, 2019—and the allocations are recorded in the respective sources' compliance accounts. Finally, after the control period but before the compliance deadline by which sources must hold allowances to cover their emissions for the control period, allowances from the reserved portions of the budget are allocated to qualifying units, any remaining reserved allowances not allocated to qualifying units are allocated among the state's existing units, and the allocations are recorded in the respective sources' compliance accounts.

In this rulemaking, the EPA would retain the overall three-step allocation process summarized above but is proposing revisions to each step to better address units in Indian country and to better coordinate the unit-level allocation process with the proposed dynamic budget-setting process discussed in Section VII.B.4 of this proposed rule. Like the allocation process established in CSAPR, the CSAPR Update, and the Revised CSAPR Update, the revised process proposed in this rulemaking would be designed to provide default allowance allocations to all units that are subject to allowance holding requirements, including, for the first time under any CSAPR trading program, an existing EGU in Indian country not covered by a state's CAA implementation planning authority. The proposed revisions to the three steps are discussed in Sections VII.B.4.a, VII.B.4.b, and VII.B.4.c of this proposed rule, respectively.

Echoing the approach to unit-level allocations followed in CSAPR, the CSAPR Update, and the Revised CSAPR Update, in this rulemaking, EPA is again proposing to provide states with several options to submit SIP revisions which, if approved, would result in the replacement of EPA's default allocations with state-determined allocations for subsequent control periods. Specifically, the proposed regulations would provide that EPA's allocations and allocation procedures will apply for the 2023 control period and, by default, for subsequent control periods unless and until a state provides state-determined allocations under an approved SIP revision. The options to submit SIP revisions that would accomplish this purpose are discussed in Section VII.D of this document. Similarly, for a covered area of Indian country not subject to a state's CAA implementation planning authority, a tribe could elect to work with the EPA under the Tribal Authority Rule to develop a full or partial tribal implementation plan under which the tribe would determine allowance allocations that would replace EPA's default allocations for subsequent control periods.

a. Set-Asides of Portions of State Emissions Budgets for New Units

As the first step in the default allocation process that the EPA has applied under CSAPR, the CSAPR Update, and the Revised CSAPR Update for any control period where a state does not employ an alternative allocation process pursuant to an approved SIP revision, EPA has reserved a portion of the state's emissions budget for potential allocation to units that are subject to allowance holding requirements and that would not otherwise receive allowance allocations in the overall allocation process. Consistent with the budget-setting approach in those rulemakings, where the state emissions budgets for all future control periods were determined in the initial rulemakings, the amounts of the reserved portions of the budgets were also determined in the initial rulemakings.[278]

The units for which portions of the budgets were reserved in set-asides have fallen into two main categories: First, units for which the data needed to determine allowance allocations does not exist at the time when the allocations for other units were being determined—*i.e.,* ''new'' units[279]—and second, units that would be left out if a state chooses to replace EPA's default allocations with state-determined allocations—*i.e.,* any units in Indian country not covered by a state's CAA implementation planning authority. Because there were no existing units in what the EPA understood to be Indian country for purposes of CSAPR, the CSAPR Update, and the Revised CSAPR Update, potential units in Indian country were considered to be a subcategory of ''new'' units, and the two types of set-asides that have been created are ''new unit set-asides'' and ''Indian country new unit set-asides.'' The principal difference between these two types of set-asides under the regulations for all of the CSAPR trading programs has been that a state can take over administration of the allowances allocated to a new unit set-aside from the EPA through an approved SIP revision but cannot take over administration of the allowances allocated to an Indian country new unit set-aside.

In this rulemaking, the EPA is proposing several revisions affecting the establishment of set-asides. The first proposed revision, which is largely unrelated to the other aspects of this rulemaking, would update the regulations for the Group 3 trading program[280] to reflect the D.C. Circuit's holding in *ODEQ* v. *EPA* that the relevant states have initial CAA implementation planning authority in non-reservation areas of Indian country until displaced by a demonstration of tribal jurisdiction over such an area.[281] Consistent with this holding, EPA is proposing to revise language in the Group 3 trading program regulations that, for purposes of allocating allowances from a given state's emissions budget, currently distinguishes between (1) the set of units within the state's borders that are not in Indian country and (2) the set of units within the state's borders that are in Indian country. As revised, the provisions would distinguish between (1) the set of units within the state's borders that are not in Indian country or are in areas of Indian country covered by the state's CAA implementation planning authority and (2) the set of units within the state's borders that are in areas of Indian country not covered by the state's CAA implementation planning authority. The revised language would more accurately distinguish which units are, or are not, covered by a state's CAA implementation planning authority, which is the underlying purpose for which the term ''Indian country'' is currently used in the allowance allocation provisions. The effect of the proposed revision would be that any

[278] Under the current regulations for each of the CSAPR trading programs, when a unit that has received allocations as an ''existing'' unit ceases operation, after a specified number of control periods the unit loses the allocations, which are then allocated to the state's new unit set-asides for subsequent control periods.

[279] A unit that has received allocations as an ''existing'' unit, then loses its allocations because of non-operation, and then later resumes operation is treated as a type of ''new'' unit for allocations purposes.

[280] As further discussed in Section VII.B.12 of this proposed rule, the EPA is also proposing to make this revision to the regulations for the other CSAPR trading programs in addition to the Group 3 trading program.

[281] For additional discussion of the *ODEQ* v. *EPA* decision and other issues related to the CAA implementation planning authority of states, tribes, and the EPA in various areas of Indian country, *see* Section IV.C.2 of this proposed rule.

units located in areas of ''Indian country'' as defined in 18 U.S.C. 1151 that are covered by a state's CAA implementation planning authority would be treated for allowance allocation purposes in the same manner as units in areas of the state that are not Indian country, consistent with the *ODEQ* holding.[282]

The remaining proposed revisions, which are interrelated, concern the types of set-asides that in the context of this proposal will best accomplish the goal of ensuring the availability of allocations to units that are subject to allowance holding requirements and that would not otherwise receive allowance allocations. One proposed revision to the types of set-asides addresses allocations to existing units in Indian country. The revised geographic scope of the Group 3 trading program under this proposal would for the first time include an existing EGU in Indian country not covered by a state's CAA implementation planning authority—the Bonanza coal-fired unit in the Uintah and Ouray Reservation within Utah's borders. In order to provide an option for Utah (or a similarly situated state in the future) to replace EPA's default allowance allocations to most existing units with state-determined allocations through a SIP revision while continuing to ensure the availability of a default allocation to the Bonanza unit (or similarly situated units in the future), the EPA proposes to revise the Group 3 trading program regulations to provide for ''Indian country existing unit set-asides.'' Specifically, for each state and for each control period where the inventory of units used to compute the state's emissions budget includes one or more existing units[283] in an area of Indian country not covered by the state's CAA implementation planning authority, the EPA would reserve a portion of the state's emissions budget in an Indian country existing unit set-aside for the unit or units. The amount of each Indian country existing unit set-aside would equal the sum of the default allocations that the units covered by the set-aside would receive if the allocations to all existing units within the state's borders were computed according to EPA's default allocation procedure (which is discussed in Section VII.B.9.b of this proposed rule). Immediately after determining the amount of a state's emissions budget for a control period (and after reserving a portion for potential allocation to new units, as discussed below), the EPA would first determine the default allocations for all existing units within the state's borders, then allocate the appropriate quantity of allowances to the Indian country existing unit set-aside, then allocate the allowances from the set-aside to the covered units in Indian country, and finally record the allocations in the sources' compliance accounts at the same time as the allocations to other sources not in Indian country. The existence of the Indian country existing unit set-aside thus would have no substantive effect unless and until the relevant state chose to replace EPA's default allowance allocations through a SIP revision, in which case the state would have the ability to establish state-determined allocations for the units subject to the state's CAA implementation planning authority while the EPA would continue to administer the Indian country existing unit set-aside for the units in Indian country not covered by the state's CAA implementation planning authority.[284] The EPA believes the proposal to establish Indian country existing unit set-asides would accomplish the objective of allowing states to control allowance allocations to units covered by their CAA implementation planning authority while providing equitable allocations to units in Indian country not covered by such authority.

The remaining revisions to the types of set-asides address the set-asides used to ensure availability of allowance allocations to *new* units in light of the division of the budget for *existing* units into a reserved portion for existing units in Indian country and an unreserved portion for other existing units. Under the current Group 3 trading program regulations, allowances for new units are provided from separate new unit set-asides and Indian country new unit set-asides. The EPA proposes to combine these two types of set-asides starting with the 2023 control period by eliminating the Indian country new unit set-asides and expanding eligibility for allocations from the new unit set-asides to include units anywhere within the relevant states' borders. However, as with the Indian country new unit set-asides under the current regulations, the EPA would continue to administer the new unit set-asides in the event a state chose to replace EPA's default allocations to existing units with state-determined allocations, thereby ensuring the availability of allocations to any new units not covered by a state's CAA implementation planning authority.

The reason for the proposed revisions to the new unit set-asides and Indian country new unit set-asides is to avoid unnecessary and potentially inequitable changes to the degree to which individual existing units contribute to, or benefit from, the new unit set-asides. Under the current regulations, the allowances used to establish these set-asides are reserved from each state emissions budget before determination of the allocations from the unreserved portion of the budget to existing units, so that certain existing units—generally those receiving the largest allocations—contribute to creation of the set-asides through roughly proportional reductions in their allocations. Later, if any allowances in a set-aside are not allocated to qualifying new units, the remaining allowances are reallocated to the existing units in proportion to their initial allocations from the unreserved portion of the budget, so that certain existing units—again, generally those receiving the largest allocations—benefit from the reallocations in rough proportion to their previous contributions.[285] The EPA believes maintaining this symmetry, where the same existing units—whether in Indian country or not—both contribute to and potentially benefit from the set-asides, is a reasonable policy objective, and doing so requires that the EPA continue to administer the new unit set-asides in the event a state chooses to replace EPA's default allocations to existing units with state-determined allocations, because otherwise the EPA would be unable to ensure that the units in Indian country would receive an appropriate

[282] The EPA notes that the units that would be treated for allocation purposes in the same manner as units not in Indian country would include units in any areas of Indian country subject to a state's CAA implementation planning authority, whether those are non-reservation areas (consistent with *ODEQ*) or reservation areas (such as areas of Indian country within Oklahoma's borders covered by the EPA's October 1, 2020 approval of Oklahoma's request under SAFETEA, as discussed in Section IV.C.2 of this proposed rule).

[283] In coordination with the dynamic budgeting process discussed in Section VII.B.4 of this proposed rule, each unit included in the unit inventory used to determine a state's emissions budget for a given control period in 2025 or a later year would be considered an ''existing'' unit for that control period for purposes of the determination of unit-level allowance allocations. In other words, there would no longer be a single fixed date that would divide ''existing'' from ''new'' units.

[284] As noted in Section VII.D, of this proposed rule a tribe could elect to work with EPA under the Tribal Authority Rule to develop a full or partial tribal implementation plan under which the tribe would determine allowance allocations for units in the relevant area of Indian country that would replace EPA's default allocations for subsequent control periods.

[285] Allowances from an Indian country new unit set-aside that are not allocated to qualifying new units are first transferred to the state's new unit set-aside, and if the allowances are still not allocated to qualifying new units, the allowances are then reallocated to the state's existing units.

share of any reallocated allowances.[286] Since the principal difference between the new unit set-asides and the Indian country new unit set-asides under the current regulations is that the EPA continues to administer the Indian country new unit set-asides in the event a state chooses to replace EPA's default allocations with state-determined allocations, if under the revised regulations the EPA would need to continue to administer the new unit set-asides, then there would no longer be any reason to establish separate Indian country new unit set-asides.

With respect to the total amounts of allowances that would be set aside for potential allocation to new units from the emissions budgets for each state, for the control periods in 2023 and 2024 (but not for subsequent control periods, as discussed below), EPA proposes to establish total set-aside amounts equal to the projected amounts of emissions from any planned units in the state for the control period, plus an additional 2% of the state emissions budget to address any unknown new units. For example, if planned units in a state are projected to emit 3% of the state's NO_X ozone season emissions budget, then the new unit set-aside for the state would be set at 5 percent, which is the sum of the minimum 2% set-aside plus an additional 3 percent for planned units. This is the same approach previously used to establish the amounts of new unit set-asides in CSAPR, the CSAPR Update, and the Revised CSAPR Update for all the CSAPR trading programs. *See, e.g.,* 76 FR 48292 (August 8, 2011). As under the Revised CSAPR Update, EPA proposes to make an exception for New York for the 2023 and 2024 control periods, establishing a total new unit set-aside amount for each control period of 5 percent of the state's emissions budget, with no additional consideration for planned units, because this approach is consistent with New York's preferences as reflected in an approved SIP addressing allowance allocations for the Group 2 trading program. Because the amounts of the state emissions budgets for the 2023 and 2024 control periods would be determined in the rulemaking, the amounts of the new unit set-asides for these control periods would also be determined in the rulemaking. The proposed amounts are shown in Tables VII.B.9.a-1 and VII.B.9.a-2 of this proposed rule.

TABLE VII.B.9.a–1—PROPOSED CSAPR NO_X OZONE SEASON GROUP 3 NEW UNIT SET-ASIDE (NUSA) AMOUNTS FOR THE 2023 CONTROL PERIOD [a]

State	Emissions budgets (tons)	New unit set-aside amount (percent)	New unit set-aside amount (tons)
Alabama	6,364	3	191
Arkansas	8,889	2	178
Delaware	384	14	54
Illinois	7,364	5	368
Indiana	11,151	2	223
Kentucky	11,640	2	233
Louisiana	9,312	2	186
Maryland	1,187	2	24
Michigan	10,718	4	429
Minnesota	3,921	2	78
Mississippi	5,024	2	100
Missouri	11,857	2	237
Nevada	2,280	6	137
New Jersey	799	2	16
New York	3,763	5	188
Ohio	8,369	5	418

Tennessee	4,234	2	85
Texas	38,284	2	766
Utah	14,981	3	449
Virginia	3,090	5	155
West Virginia	12,478	2	250
Wisconsin	5,963	2	119
Wyoming	9,125	3	274

Table Notes:

[a] In the event a final rule in this rulemaking becomes effective after May 1, 2023, the emissions budgets for the 2023 control period would be adjusted under the rule's proposed transitional provisions to ensure the new budgets would apply only after the rule's effective date, even though the revised Group 3 trading program would be implemented for most sources as of the start of the 2023 ozone season on May 1, 2023. The 2023 budget amounts shown in Table VII.B.9.a–1 do not reflect these possible adjustments. The transitional provisions are discussed in Section VII.B.11 of this proposed rule.

[286] If units in Indian country were unable to share in the benefits of reallocation of allowances from the new unit set-asides, it would be possible to achieve a different form of symmetry by simultaneously exempting the units in Indian country from the obligation to share in the contribution of allowances to the new unit set-asides. However, some stakeholders might view this alternative as potentially inequitable because existing units in Indian country would then make no contributions toward the new unit set-aside while other existing units would still be required to do so.

TABLE VII.B.9.a–2—PROPOSED CSAPR NO_X OZONE SEASON GROUP 3 NEW UNIT SET-ASIDE (NUSA) AMOUNTS FOR THE 2024 CONTROL PERIOD

State	Emissions budgets (tons)	New unit set-aside amount (percent)	New unit set-aside amount (tons)
Alabama	6,306	3	189
Arkansas	8,889	2	178
Delaware	434	14	61
Illinois	7,463	5	373
Indiana	9,391	2	188

Michigan	10,718	4	429
Minnesota	3,921	2	78
Mississippi	4,400	2	88
Missouri	11,857	2	237
Nevada	2,372	6	142
New Jersey	799	2	16
New York	3,763	5	188
Ohio	8,369	5	418
Oklahoma	9,573	2	191
Pennsylvania	8,855	3	266
Tennessee	4,234	2	85
Texas	38,284	2	766
Utah	15,146	3	454
Virginia	2,814	5	141
West Virginia	12,478	2	250
Wisconsin	5,057	2	101
Wyoming	8,573	3	257

For control periods in 2025 and later years, the EPA proposes to allocate a total of 2% of each state emissions budget to a new unit set-aside, with no additional amount for planned new units. The amounts of the set-asides for each state and control period would be computed when the emissions budgets for the control period are established, by May 1 of the year before the year of the control period. The procedure for determining the amounts of the set-asides based on the amounts of the state emissions budgets would be codified in the Group 3 trading program regulations and would reflect the same percentage of the emissions budget for all states.

The purpose of the proposed change to the procedure for establishing the amounts of the set-asides is to coordinate with the dynamic budget-setting process that would also become effective as of the 2025 control period. As discussed in Section VII.B.4 of this proposed rule, under the dynamic budget-setting process, each state's budget for each control period would be computed using fleet composition information and the total ozone season heat input reported by all affected units in the state for the latest control period before the budget-setting computations, which would be 2 years before the control period for which the budgets are being determined. (For example, 2025 emissions budgets would be based on 2023 fleet composition and heat input data.) Moreover, as discussed in Section VII.B.9.b of this proposed rule, all units whose heat input was used in the budget computations for a given control period would be eligible to receive allocations as ''existing'' units in that control period. Consequently, by the 2025 control period, all or almost all units that commence commercial operation before issuance of a final rule in this rulemaking would be considered ''existing'' units for purposes of budget-setting and allocations, and units commencing commercial operation after issuance of a final rule generally would be considered ''existing'' units for all but their first two full control periods of operation (and possibly a preceding partial control period). Given that new units would not be relying on the new unit set-asides as a permanent source of allowances, as is the case for ''new'' units under the other CSAPR trading programs, the EPA believes smaller set-asides would be sufficient.

The EPA requests comment on the proposals to establish Indian country existing unit set-asides, eliminate Indian country new unit set-asides, and expand eligibility for allocations from new unit set-asides to include units in Indian country for control periods in 2023 and later years. In the alternative, the EPA requests comment on establishing emissions budgets (and assurance levels and new unit set-asides) for the Uintah and Ouray Reservation separate from the emissions budgets (and assurance levels, new unit set-asides, and Indian country new unit set-asides) established for the remaining lands within Utah's borders, and otherwise retaining the structure of prior CSAPR trading programs' approach to allocations to new units in Indian country (*i.e.,* keeping the Indian country new unit set-asides, and not expanding eligibility for allocations from the new unit set-asides). The EPA also requests comment on the proposed new unit set-aside amounts for the 2023 and 2024 control periods, the proposed procedure for establishing the new unit set-aside amounts for the control periods in 2025 and later years, and the proposed procedure for establishing the Indian country existing unit set-aside amounts for the control periods in 2023 and later years.

b. Allocations to Existing Units, Including Units That Cease Operation

In conjunction with the new and revised state emissions budgets for the Group 3 trading program proposed in this rulemaking, the EPA is necessarily proposing new unit-level allocations of Group 3 allowances to existing units.[287]

[287] The proposed revisions to the procedures for computing unit-level allowance allocations in this rulemaking apply only to the Group 3 trading

The procedure that the EPA proposes to employ to compute the unit-level allocations is very similar but not identical to the procedure used to compute unit-level allocations for units subject to the Group 3 trading program in the Revised CSAPR Update. The steps of the proposed procedure for determining allocations from each state emissions budget for each control period, are described in detail in the Unit-Level Allowance Allocations Proposed Rule TSD. The steps are summarized later, with changes from the procedure followed in the Revised CSAPR Update noted.

In the first step, the EPA would identify the list of units eligible to receive allocations for the control period, which would be the same set of units whose heat input was used in computing the state's emissions budget for the control period (except any units that are included in the budgets as ''new'' units, which would receive allocations from the new unit set-asides instead). The unit inventories used to compute emissions budgets for the 2023 and 2024 control periods would be determined in the rulemaking in the same manner as in the Revised CSAPR Update. The unit inventories used to compute emissions budgets and unit-level allocations for control periods in 2025 and later years would be determined in the year before the control period in question based on the latest reported emissions and operational data, which is an extension of the methodology used in the Revised CSAPR Update to reflect more recent data (for example, the unit inventories used to compute 2025 budgets and allocations would reflect reported data for the 2023 control period). The procedures for updating the unit inventories for 2023 and 2024 and for 2025 and beyond are discussed in Section VII.B.4 of this proposed rule, and the criteria that the EPA has applied to determine whether a unit's scheduled retirement is sufficiently certain to serve as a basis for adjusting emissions budgets and unit-level allocations are discussed in Section VI.B and in the Ozone Transport Policy Analysis Proposed Rule TSD. With regard to the use of the inventories from the budget-setting procedure in setting unit-level allocations, in the Revised CSAPR Update, the inventories used to establish the budgets were generally also used to compute unit-level allocations, except that units that commenced construction after January 1, 2019, were not treated as eligible to receive allocations as existing units and instead received allocations from the new unit set-asides. Under this rulemaking, any unit whose heat input is used to set a state's emissions budget for a given control period would also be eligible to receive allocations as an existing unit for that control period.

The EPA notes that this proposal to base the list of eligible units on the list of units that reported heat input in the control period 2 years earlier than the control period for which allocations are being determined would represent a revision to the current regulations concerning the treatment of allocations to retired units. Under the current regulations, units that cease operations for 2 consecutive control periods continue to receive allocations as existing units for 3 additional years (that is, a total of 5 years) before the allowances they would otherwise have received are reallocated to the new unit set-aside for the state. Under the proposal in this rulemaking, units that cease operation would receive allocations for only two full control periods of non-operation. While the EPA has in prior transport rulemakings noted a qualitative concern that ceasing allowance allocations prematurely could distort the economic incentives of EGUs to continue operating when retirement is more economical, the EPA believes current market conditions are such that a continuation of allowance allocations to retiring units likely has no more than a de minimis effect on the consideration of an EGU whether to retire or not.

In the second step of the procedure for determining allocations to existing units, the EPA would compile a database containing for each eligible unit the unit's historical heat input and total NO_X emissions data for the five most recent ozone seasons. For each unit, the EPA would compute an average heat input value based on the three highest non-zero heat input values over the 5-year period, or as the average of all the non-zero values in the period if there are fewer than three non-zero values. For each unit, the EPA would also determine the maximum total NO_X emissions value over the 5-year period. These procedures are nearly identical to the procedures used in the Revised CSAPR Update, with two exceptions. First, instead of using only the data available at the time of the rulemaking, for each control period the EPA would use data from the most recent five control periods for which data had been reported. (For example, for the 2025 control period, the EPA would use data for the 2019–2023 control periods.) Second, to simplify the data compilation process, the EPA would use only a five-year period for NO_X mass emissions, in contrast to the 8-year period used in the Revised CSAPR Update for NO_X mass emissions.

In the third step of the procedure for determining allocations to existing units in each state, the EPA would allocate the available allowances for that state among the state's eligible units in proportion to the share each unit's average heat input value represents of the total of the average heat input values for all the state's eligible units, but not more than the unit's maximum total NO_X value. If the allocations to one or more units are curtailed because of the units' maximum total NO_X values, the EPA would iterate the calculation procedure as needed to allocate the remaining allowances, excluding from each successive iteration any units whose allocations have already reached their maximum total NO_X values. This calculation procedure is identical to the calculation procedure used in the Revised CSAPR Update (as well as the CSAPR Update and CSAPR).

The unit-level allocations for the 2023 and the 2024 control periods would be determined in the rulemaking based on the emissions budgets for those control periods also determined in the rulemaking and would be recorded 30 days after the effective date of the final rule (in order to provide time to execute the proposed recall of 2023 and 2024 Group 2 allowances, as discussed in Section VII.B.11.c of this proposed rule). This proposed recordation schedule represents a revision to the recordation schedule currently in the Group 3 trading program regulations which calls for allocations of 2023 and 2024 Group 3 allowances to existing units to be recorded on July 1, 2022. The EPA notes that for the three states with approved SIP revisions establishing their own methodologies for allocating Group 2 allowances—Alabama, Indiana, and New York—EPA proposes to follow those methodologies to the extent possible in developing the allocations of Group 3 allowances for the 2023 and 2024 control periods. For the amounts of the proposed allocations to existing units for the 2023 and 2024 control periods, see the ''Unit-Level Allowance Allocations Proposed Rule TSD'' in the docket.

The unit-level allocations for each control period in 2025 or a later year would be computed immediately following the determination of the emissions budgets for the control period. The EPA would perform the

program. In this rulemaking, the EPA is not proposing changes to or reopening the methodology for computing the amounts of allowances allocated to any unit under any other CSAPR trading program.

computations and issue a notice of data availability concerning the preliminary unit-level allocations for each control period by March 1 of the year before the control period. Objections to the data and preliminary computations could be submitted for 30 days, and the EPA would make any appropriate revisions and issue another notice of data availability by May 1 of the year before the control period. The EPA would then record the allocations by July 1 of the year before the control period. This proposed recordation schedule—which is necessitated by the fact that the amounts of the unit-level allocations to be recorded would not be known until the year before the control period, as just discussed—represents a revision to the recordation schedule currently in the Group 3 trading program regulations which calls for allocations of Group 3 allowances to existing units for control periods in 2025 and later years to be recorded on July 1 of the third year before the year of the control period. The EPA does not propose to follow any state-specific methodologies as part of the procedures for determining default unit-level allocations of Group 3 allowances for control periods in 2025 or later years, but any state wishing to use a procedure different than EPA's default allocations procedure could do so by obtaining approval of a SIP revision, as discussed in Section VII.D of this proposed rule.

In the case of any states making state-determined allocations under approved SIP revisions, the allocations would have to be submitted to EPA by June 1 of the year before the control period and the EPA would record the allocations by July 1 of the year before the control period. The proposed submission deadline would represent a revision of the current deadline of June 1 of the year 3 years before the control period, and the proposed recordation deadline would represent a revision of the current deadline of July 1 of the year 3 years before the control period. The purpose of revising the submission deadline is to provide each state for which the EPA has approved a SIP revision authorizing state-determined allowance allocations a period of time in which to apply the state's preferred allocation methodology to the state's trading budget for the appropriate control period. Because the state trading budgets under the Group 3 trading program as revised would not be known until May 1 of the year before each control period, states could not determine unit-level allocations of the budgets using their own methodologies significantly before June 1 of the year before the control period. Submission by June 1 would allow the allowance allocations to the units in the state to be recorded by July 1 of the year before the control period, simultaneously with the recordation of allocations to units in states where the EPA determines the allocations.

As an exception to all of the recordation deadlines that would otherwise apply, the EPA proposes to not record any allocations of Group 3 allowances in a source's compliance account unless that source has complied with the requirements to surrender previously allocated 2023–2024 Group 2 allowances. The surrender requirements are necessary to maintain the previously established levels of stringency of the Group 2 trading program for the states and sources that remain subject to that program under this final rule. The EPA finds that it is reasonable to condition the recordation of Group 3 allowances on compliance with the surrender requirements because the condition will spur compliance and will not impose an inappropriate burden on sources. The EPA considers establishment of this condition, which will facilitate the continued functioning of the Group 2 trading program, to be an appropriate exercise of the Agency's authority under CAA section 301 (42 U.S.C. 7601) to prescribe such regulations as are necessary to carry out its functions under the Act.

The EPA requests comment on the proposed revisions to the procedures for allocating allowances to existing units under the Group 3 trading program, the deadlines for recording the allocations, and the deadlines for submission of state-determined allowance allocations to the EPA.

c. Allocations From Portions of State Emissions Budgets Set Aside for New Units

As promulgated in the Revised CSAPR Update, the Group 3 trading program regulations provide for the EPA to allocate allowances from each new unit set-aside and Indian country new unit set-aside after the end of the control period at issue. The regulations call for the EPA to allocate allowances to any eligible ''new'' units in the state in proportion to their respective emissions during the control period, up to the amounts of those emissions if the relevant set-aside contains sufficient allowances, and not exceeding those emissions. An eligible new unit for purposes of allocations from a set-aside for a given control period is generally any unit in the relevant area that reported emissions subject to allowance surrender requirements during the control period and that was not eligible to receive an allowance allocation as an ''existing'' unit for the control period. Any allowances remaining in an Indian country new unit set-aside after the allocations to new units are transferred to the new unit set-aside for the state for potential allocation to new units in non-Indian country areas of the state, and any allowances remaining in a new unit set-aside after the allocations to new units are reallocated to the existing units in the state in proportion to those units' previous allocations for the control period as existing units. The EPA issues a notice of data availability concerning the proposed allocations by March 1 following the control period, provides an opportunity for submission of objections, and issues a final notice of data availability and record the allocations by May 1 following the control period, one month before the June 1 compliance deadline.

In this rulemaking, as discussed in Section VII.B.9.a of this document, the EPA is proposing to eliminate Indian country new unit set-asides after the 2022 control period and to expand eligibility for allocations from each state's new unit set-aside for a control period in 2023 or a later year to include units in Indian country within the state's borders, regardless of whether the area of Indian country is covered by the state's CAA implementation planning authority. The reasons for these proposed revisions are discussed in Section VII.B.9.a of this proposed rule. The EPA is not proposing any substantive revisions to the current Group 3 trading program provisions governing the procedures for allocating allowances from a state's new unit set-aside for a control period to the eligible units within the state's borders.[288]

This EPA notes that the proposed revisions to other provisions of the Group 3 trading program regulations discussed elsewhere in this document will reduce the portions of the state emissions budgets that are allocated through the new unit set-asides. Specifically, because the new unit set-asides will no longer receive any additional allowances when units retire, for control periods in 2025 and later years the amounts of allowances in the new unit set-asides will always be 2 percent of the respective state emissions budgets for the respective control periods. This reduction in the size of the

[288] As discussed in Section X of this proposed rule, the EPA is proposing to relocate some of the regulatory provisions relating to administration of the new unit set-asides and is also proposing to remove certain provisions that would be made obsolete by proposed revisions to other provisions of the Group 3 trading program regulations.

new unit set-asides is appropriate given that the number of consecutive control periods for which any particular unit is likely to receive allocations from a state's new unit set-aside will be reduced to two or three before the unit becomes eligible to receive allocations from the unreserved portion of the state's emissions budget. This approach contrasts with the approach under the other CSAPR trading programs where a new unit never becomes eligible to receive allocations from the unreserved portion of the emissions budget and where the new unit set-aside therefore needs to grow to accommodate an ever-increasing share of the state's total emissions.

The EPA also notes that, as discussed in Sections VII.D.2 and VII.D.3 of this proposed rule, in the event that a state chooses to replace EPA's default allowance allocations under the Group 3 trading program with state-determined allocations through a SIP revision, the EPA will continue to administer the portion of each state emissions budget reserved in a new unit set-aside in order to ensure the availability of allowance allocations to new units in any areas of Indian country within the state not covered by the state's CAA implementation planning authority.

d. Incorrectly Allocated Allowances

The Group 3 trading program regulations as promulgated in the Revised CSAPR Update include provisions addressing incorrectly allocated allowances. With regard to any allowances that were incorrectly allocated and are subsequently recovered, the current provisions generally call for the recovered allowances to be reallocated to other units in the relevant state (or Indian country within the borders of the state) through the process for allocating allowances from the new unit set-aside (or Indian country new unit set-aside) for the state. If the procedures for allocating allowances from the set-asides have already been carried out for the control period for which the recovered allowances were issued, the allowances would be allocated through the set-asides for subsequent control periods.

The EPA continues to view the current provisions for disposition of recovered allowances as reasonable in the case of any allowances that are recovered before the deadline for recording allocations of allowances from the new unit set-aside for the control period for which the recovered allowances were issued. However, in the case of any allowances that are recovered after that deadline, adding the recovered allowances to the new unit set-aside for a subsequent control period, as provided in the current regulations, would be inconsistent with the proposed trading program enhancements discussed elsewhere in this document, where the amounts of allowances provided in the state emissions budgets for each control period are designed to reflect the most current available information on fleet composition and utilization and where the quantities of banked allowances available for use in each control period are recalibrated for consistency with the state emissions budgets. The EPA therefore proposes that, starting with allowances allocated for the 2024 control period, any incorrectly allocated allowances that are recovered after the deadline for allocating allowances from the new unit set-aside for that control period (*i.e.,* May 1 of the year following the control period) would be transferred to a surrender account instead of being reallocated to other units in the state.

The EPA requests comment on the proposed revision to the provisions for disposition of incorrectly allocated allowances that are recovered after the deadline for allocating allowances from the new unit set-asides for the control periods for which the recovered allowances were issued.

10. Other Trading Program Provisions

This section discusses how certain existing provisions of the Group 3 trading program regulations would apply to sources that become subject to the program as a result of a final rule in this rulemaking as well as certain proposed changes to reporting requirements associated with the proposed backstop daily NO_X emissions rates for coal-fired units.

a. Designated Representative Requirements

As noted in Section VII.B.1.a of this document, a core design element of all the CSAPR trading programs is the requirement that each source must have a designated representative who is authorized to represent all of the source's owners and operators and is responsible for certifying the accuracy of the source's reports to the EPA and overseeing the source's Allowance Management System account. The necessary authorization of a designated representative is certified to the EPA in a certificate of representation. The EPA is not proposing any change to the Group 3 trading program's designated representative provisions in this rulemaking.

The existing designated representative provisions in the Group 3 trading program regulations already provide that EPA will interpret references to the Group 2 trading program in certain documents—including a certificate of representation as well as a notice of delegation to an agent or an application for a general account—as if the documents referenced the Group 3 trading program instead of the Group 2 trading program. For these reasons, sources that currently participate in the Group 2 trading program and that transition to the Group 3 trading program because of a final rule in this rulemaking will not need to submit any new forms as part of the transition, because previously submitted forms will be valid for purposes of the Group 3 trading program.

Designated representatives for sources that are newly affected under the Group 3 trading program and that are not currently affected under the Group 2 trading program would need to submit new or updated certificates of representation. If the source is also affected under other CSAPR trading programs or the Acid Rain Program, the source's designated representative for all of the programs must be the same individual. The EPA will not record any Group 3 allowances allocated to a source in the source's compliance account until the source has a properly authorized designated representative.

b. Monitoring and Reporting Requirements

The Group 3 trading program requires monitoring and reporting of emissions and heat input data in accordance with the provisions of 40 CFR part 75. In this rulemaking, the EPA is not proposing any change to these provisions of the Group 3 trading program except with respect to the monitor certification deadline for certain units. The EPA is also not proposing any changes to the monitoring requirements in 40 CFR part 75 for units subject to such requirements. However, because of the proposed geographic expansion of the Group 3 trading program, certain units that were not previously subject to monitoring requirements under 40 CFR part 75 would become subject to such requirements. Also, the EPA is proposing certain additional recordkeeping and reporting requirements that would be met using some of the data that are already collected by the required monitoring systems.[289]

[289] The EPA is not proposing to amend the existing provisions of the Group 3 trading program regulations that govern whether units covered by the program must record and report required data on a year-round basis or may elect to record and

Continued

Under 40 CFR part 75, a unit has several options for monitoring and reporting, including the use of continuous emissions monitoring systems (CEMS), excepted monitoring methodologies for qualifying gas- or oil-fired units that rely in part on fuel-flow metering in combination with CEMS-based or testing-based NO_X emissions rate data, low-mass emissions monitoring for certain non-coal-fired, low emitting units, and alternative monitoring systems approved by the Administrator through a petition process. In addition, sources can submit petitions to the Administrator for alternatives to individual monitoring, recordkeeping, and reporting requirements specified in 40 CFR part 75. Each CEMS must undergo rigorous initial certification testing and periodic quality assurance testing thereafter, including the use of relative accuracy test audits and 24-hour calibrations. In addition, when a monitoring system is not operating properly, standard substitute data procedures are applied to produce a conservative estimate of emissions for the period involved. Further, 40 CFR part 75 requires electronic submission of quarterly emissions reports to the Administrator, in a format prescribed by the Administrator. The reports would contain all of the data required concerning ozone season NO_X emissions.

For units exhausting to common stacks, 40 CFR part 75 includes options that often allow monitoring to be conducted at the common stack on a combined basis for all the units as an alternative to installing separate monitoring systems for the individual units in the ductwork leading to the common stack. The units then keep records and report hourly and cumulative NO_X mass emissions and in many cases heat input data on a combined basis for all units exhausting to the common stack. With respect to heat input data, but not NO_X mass emissions data, most such units are also required to record and report hourly and cumulative data on an individual-unit basis, and where necessary they typically compute the necessary unit-level hourly heat input values by apportioning the combined hourly heat input values for the common stack in proportion to the individual units' recorded hourly output of electricity or steam. *See generally* 40 CFR 75.72.

In this rulemaking, the proposed provisions governing default unit-level allowance allocations, backstop daily NO_X emissions rates for certain coal-fired units, and secondary emissions limitations for units contributing to assurance level exceedances would all require the use of unit-level reported data on NO_X mass emissions (or unit-level NO_X emissions rates computed in part based on unit-level reported data on NO_X mass emissions). To facilitate the implementation of these proposed provisions, the EPA is proposing to require all units covered by the Group 3 trading program exhausting to common stacks to record and report unit-level hourly and cumulative NO_X mass emissions data starting with the 2024 control period. To obtain the necessary unit-level hourly mass emissions values, the EPA proposes to allow the units to apportion hourly mass emissions values determined at the common stack in proportion to the individual units' recorded hourly heat input. The proposed apportionment procedure would be very similar to the apportionment procedure that most such units already apply to compute reported unit-level heat input data. Because the additional required data values would be obtained through apportionment, implementation of the proposed additional recordkeeping and reporting requirements would necessitate a one-time update to the units' data acquisition and handling systems but would not require any changes to the monitoring systems already needed to meet other requirements under 40 CFR part 75. In most cases, the EPA expects that the reported values computed through these apportionment procedures would reasonably approximate the values that could be obtained through installation and operation of separate monitoring systems for the individual units, because the units exhausting to the common stack would be expected to have similar NO_X emissions rates. However, the EPA also recognizes that at some plants, unit-level values determined through apportionment based on electricity or steam output could overstate the reported NO_X mass emissions for some units and correspondingly understate the reported NO_X mass emissions for other units. While the EPA has not at this time identified any reason to expect such potential overstatement and understatement to cause the proposed requirements in this rule to be less stringent overall, the Agency requests comment on whether units in particular situations should be required to obtain the necessary hourly mass emissions values through installation and operation of monitoring systems at the individual-unit level.[290]

In addition, to implement the proposed backstop daily NO_X emissions rates during the ozone season for certain coal-fired units, the EPA is proposing to require additional recordkeeping and reporting requirements for these units. Specifically, starting in 2024 for coal-fired units with existing SCR controls serving generators larger than 100 MW, and starting in 2027 for other coal-fired units serving generators larger than 100 MW (except circulating fluidized bed units), the units would be required to record and report total daily NO_X emissions and total daily heat input, daily average NO_X emissions rate, and daily NO_X emissions exceeding the applicable backstop daily NO_X emissions rates. The units would also be required to record and report cumulative NO_X emissions exceeding the backstop daily NO_X emissions rates for the ozone season. These data would be used to determine the allowance surrender requirements related to the backstop daily NO_X emissions rates. As with the additional recordkeeping and reporting requirements discussed above for units exhausting to common stacks, implementation of the additional recordkeeping and reporting requirements for coal-fired units would necessitate a one-time update to the units' data acquisition and handling systems but would not require any changes to the monitoring systems already needed to meet other requirements under 40 CFR part 75.

In states whose sources currently participate in the Group 3 trading program, as well as states whose sources participate in the Group 2 trading program and would transition to the

report required data on an ozone season-only basis. *See* 40 CFR 97.1034(d)(1); *see also* 40 CFR 75.74(a)–(b). Thus, for units that are required or elect to report other data on a year-round basis, the proposed additional recordkeeping and reporting requirements would also apply year-round, while for units that are allowed and elect to report other data on an ozone season-only basis, the proposed additional requirements would also apply for the ozone season only.

[290] For example, as noted in Section VII.B.7 of this proposed rule, there are currently five plants in the states covered by this proposal where SCR-equipped coal-fired units and non-SCR-equipped coal-fired units exhaust to common stacks. If the owners and operators of these plants choose to report apportioned NO_X mass emissions data in preference to installing and operating separate monitoring systems, the likely effect would be to overstate reported NO_X mass emissions for the SCR-equipped units and correspondingly understate reported NO_X mass emissions for the non-SCR equipped units. This would make compliance with the proposed backstop daily NO_X emissions rate more challenging for the SCR-equipped units. If the EPA does not require the owners and operators to install and operate separate monitoring systems for the individual units in a final rule in this rulemaking, the owners and operators would still have the option to do so if they believed it would be to their benefit.

Group 3 trading program under this proposal, units that are not subject to the proposed backstop daily NO_X emissions rates would not need to make any changes to their current monitoring and reporting as a result of the transition. The sources in states currently in the Group 2 trading program would be required to begin monitoring and reporting of NO_X emissions and operational data for purposes of the Group 3 trading program as of May 1, 2023, the start of the 2023 control period.

In states whose sources do not currently participate in the Group 2 trading program, any sources that currently report ozone season NO_X mass emissions according to 40 CFR part 75 to comply with SIP requirements and that are not subject to the proposed backstop daily NO_X emissions rates similarly would not need to make any changes to their current monitoring and reporting as a result of the transition. Other sources in these states that currently report SO_2 and NO_X emissions data according to 40 CFR part 75 under other CSAPR trading programs or the Acid Rain Program would not need to certify new monitoring systems for purposes of the Group 3 trading program but would need to update their monitoring plans and possibly update the software in their data acquisition and handling systems to compute certain additional values from the measurements that are already being recorded. All the sources in these states that already have monitoring systems certified under 40 CFR part 75 would be required to begin monitoring and reporting of NO_X emissions and operational data for purposes of the Group 3 trading program as of the later of May 1, 2023, or the effective date of the final rule.[291]

Finally, any sources that meet the applicability criteria of the Group 3 trading program and that do not currently report NO_X emissions data to the EPA under 40 CFR part 75 would need to certify new monitoring systems in accordance with part 75 before they would be required to monitor and report emissions for purposes of the Group 3 trading program. The units the EPA has been able to identify as potentially affected under this proposal that may need to certify new monitoring systems are listed in Table VII.B.3–1 (along with some other units that are potentially affected under this proposal and that already have certified monitoring systems). Because each of the listed units commenced commercial operation more than 180 days before the date when a final rule in this rulemaking would become effective, under the current Group 3 trading program regulations (*i.e.,* without the revisions proposed in this section), each unit's monitor certification deadline would generally be the effective date of the final rule. To ensure that the final rule does not impose monitor installation and certification requirements on these units before the effective date of the final rule, the EPA is proposing to revise the Group 3 trading program's monitor certification deadline provisions to establish a 180-day window for certification of the new monitoring systems after the effective date of a final rule in this rulemaking for units that do not already have monitoring systems certified under 40 CFR part 75, similar to the 180-day window already provided to units commencing commercial operation after (or less than 180 days before) the final rule's effective date. The 180th day for units in this situation would likely fall after the end of the 2023 ozone season, with the result that the certification deadline would be extended until May 1, 2024, the first day of the 2024 ozone season. Because the program's allowance holding requirements apply to a given unit only after that unit's monitor certification deadline, the units in this situation consequently would become subject to allowance holding requirements as of the 2024 ozone season rather than the 2023 ozone season.[292]

The EPA requests comment on the proposed revisions to the recordkeeping and reporting provisions in 40 CFR part 75 and the proposed establishment of a 180-day window for certification of new monitoring systems after the effective date of a final rule in this rulemaking for units that do not already have monitoring systems certified under 40 CFR part 75. As discussed above, with respect to units exhausting to common stacks, the EPA also requests comment on whether units in particular situations should be required to obtain hourly NO_X mass emissions values through installation and operation of monitoring systems at the individual-unit level instead of being allowed to obtain values for individual units through apportionment of the combined values for the units exhausting to the common stack.

11. Transitional Provisions

This section discusses several provisions that the EPA proposes to implement in order to address the transition of sources into the Group 3 trading program as revised. The purposes of the proposed transitional provisions are generally the same as the purposes of the analogous transitional provisions promulgated in the Revised CSAPR Update: First, accounting for the possibility that the effective date of a final rule in this rulemaking will fall after the starting date of the first affected ozone season (which in this case is, May 1, 2023); second, establishing an appropriately-sized initial allowance bank through the conversion of previously banked allowances; and third, preserving the intended stringency of the Group 2 trading program for the sources that will continue to be subject to that program.[293] However, the sources that would be participants in the revised Group 3 trading program under this proposal are transitioning from several different starting points—with some sources already in the Group 3 trading

[291] For units that currently report under 40 CFR part 75 only for annual programs and that use the optional low mass emissions methodology in 40 CFR 75.19, an additional consideration could arise. Specifically, eligibility to use the low mass emissions methodology for reporting ozone season NO_X mass emissions is restricted to units demonstrating that they have not exceeded or will not exceed a maximum of 50 tons of NO_X per ozone season. In theory, some units that would be eligible to use the low mass emissions methodology for purposes of annual programs only might lose that eligibility because of the 50-ton ozone season cap (which does not apply to units reporting for annual programs only). Based on the emissions reports submitted for the 2018–2020 control periods under the Acid Rain Program and the CSAPR annual programs, none of the existing units that currently report under 40 CFR part 75 for annual programs only and that would be added to the Group 3 trading program under the proposal are presently in this theoretical situation.

[292] Table VII.B.3–1 of this proposed rule lists 22 existing units in Delaware, Nevada, Utah, and Wyoming that appear to meet the Group 3 trading program's general applicability criteria and that do not already report NO_X emissions data to the EPA under 40 CFR part 75 pursuant to any other existing regulatory requirements. As noted in Section VII.B.3 of this proposed rule, six of the 22 listed units have reported that they may retire before the 2023 ozone season, and the possibility exists that up to nine of the remaining listed units could qualify for an exemption from the Group 3 trading program available to certain cogeneration units. EPA therefore projects that the revision to the monitor certification deadline proposed in this section, and the related delay in allowance holding requirements from 2023 to 2024, could apply to between seven and 22 units, with the total estimated 2021 ozone season NO_X emissions for all such units ranging between 250 and 450 tons. During the period before allowance holding requirements apply to the units—*i.e.,* the period from the effective date of a final rule in this rulemaking until the start of the 2024 control period—other requirements of the program would still apply, such as the requirement for submission of a certificate of representation by a designated representative and the requirements related to installation and certification of required monitoring systems.

[293] The EPA is not proposing to create a ''safety valve mechanism'' in this rulemaking analogous to the safety valve mechanism established under the Revised CSAPR Update.

program under its current regulations, some sources coming from the Group 2 trading program, and some sources not currently participating in any seasonal NO_X trading program. EPA is therefore proposing transitional provisions that differ across the sets of potentially affected sources based on the sources' different starting points.

a. Prorating Emissions Budgets, Assurance Levels, and Unit-Level Allowance Allocations in the Event of an Effective Date After May 1, 2023

While it is EPA's intent for a final rule in this rulemaking to take effect before the start of the Group 3 trading program's 2023 control period on May 1, 2023, it is possible that the final rule's effective date will fall after that date. The EPA proposes to address this contingency by determining the amounts of emissions budgets and unit-level allowance allocations on a full-season basis in the rulemaking and by also including provisions in the revised regulations to prorate the full-season amounts as needed to ensure that no sources become subject to new or more stringent regulatory requirements before the final rule's effective date.[294] Variability limits and assurance levels for 2023 would be computed using the appropriately prorated emissions budgets amounts, and unit-level allocations would also be prorated.[295]

As discussed in Section VII.B.2 of this proposed rule, in the case of states (and Indian country within the states' borders) whose sources do not currently participate in either the Group 2 trading program or the Group 3 trading program—Delaware, Minnesota, Nevada, Utah, and Wyoming—the sources would begin participating in the Group 3 trading program on the later of May 1, 2023, or the final rule's effective date. For these states, in the rulemaking the EPA would compute the full-season emissions budgets that would apply for the entire 2023 control period if the final rule becomes effective no later than May 1, 2023, and is therefore in effect for the entire 153-day control period from May 1, 2023, through September 30, 2023. If the final rule becomes effective after May 1, 2023, the EPA would determine prorated emissions budgets by multiplying each full-season emissions budget by the number of days from the rule's effective date through September 30, 2023, dividing by 153 days, and rounding to the nearest allowance. The prorated variability limits would be computed as 21 percent of the prorated emissions budgets, rounded to the nearest allowance, yielding prorated assurance levels that equal 121 percent of the prorated emissions budgets. To determine unit-level allocation amounts from the prorated emissions budgets, the EPA would determine full-season allocation amounts in the rulemaking and would determine preliminary prorated allocation amounts in the same manner as described for the emissions budgets previously. The preliminary prorated amounts of the largest unit-level allowance allocations for each state would then each be adjusted up or down by one allowance as needed to cause the sum of the final prorated unit-level allowance allocations for the state to equal the state's prorated emissions budget. All calculations required to determine the prorated emissions budgets and variability limits and the unit-level allocations for the 2023 control period would be carried out as soon as possible after the EPA learns the effective date of a final rule in this rulemaking (which is expected to be approximately 60 days after the date of the final rule's publication in the **Federal Register**). The unit-level allocations for both the 2023 and 2024 control periods would be recorded in facilities' compliance accounts approximately 30 days after the final rule's effective date, as discussed in Section VII.B.9.b of this proposed rule.

In the case of states (and Indian country within the states' borders) whose sources currently participate in the Group 3 trading program—Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, New Jersey, New York, Ohio, Pennsylvania, Virginia, and West Virginia—the sources would continue to participate in the Group 3 trading program for the 2023 control period, subject to prorating procedures designed to ensure that the changes in 2023 emissions budgets and assurance levels would not substantively affect the sources' requirements prior to the rule's effective date. For these states, in the rulemaking the EPA would compute the full-season emissions budgets that would apply for the entire 2023 control period if the final rule becomes effective no later than May 1, 2023, but the EPA would not remove from the regulations the full-season emissions budgets for the 2023 control period that were established in the Revised CSAPR Update rulemaking. Instead, the EPA would include both sets of emissions budgets and variability limits in the regulations, along with a provision indicating that the emissions budgets promulgated in the Revised CSAPR Update would apply on a prorated basis for the portion of the 2023 control period before the final rule's effective date and the emissions budgets established in this rulemaking would apply on a prorated basis for the portion of the 2023 control period on and after the final rule's effective date. Under this provision, the EPA would determine a blended emissions budget for each state for the 2023 control period, computed as the sum of the appropriately prorated amounts of the state's current and revised emissions budgets. (For example, if the final rule became effective on the eleventh day of the 153-day 2023 control period, the blended emissions budget would equal the sum of 10/153 times the current emissions budget plus 143/153 times the revised emissions budget, rounded to the nearest allowance.) Blended variability limits for the 2023 control period would be computed as 21% of the blended emissions budgets, yielding blended assurance levels equal to 121 percent of the blended emissions budgets. Unit-level allocations would be determined by applying the allocation procedure described in Section VII.B.9 of this proposed rule to the blended budgets. In the case of states (and Indian country within the states' borders) whose sources currently participate in the Group 2 trading program—Alabama, Arkansas, Mississippi, Missouri, Oklahoma, Tennessee, Texas, and Wisconsin—the sources would begin to participate in the Group 3 trading program as of May 1, 2023, regardless of the final rule's effective date, as discussed in Section VII.B.2 of this proposed rule, subject to prorating procedures designed to ensure that the transition from the Group 2 trading program to the Group 3 trading program would not substantively affect the sources' requirements prior to the rule's effective date. The prorating procedures for these states would mirror the procedures for the states currently in the Group 3 trading program, except that because no emissions budgets currently appear in the Group 3 trading program regulations for the states that are currently covered by the Group 2 trading program, the EPA would add two sets of emissions budgets for these states to the Group 3 trading program regulations: First, the states' emissions budgets for the 2023 control period that currently appear in the Group 2 trading

[294] As discussed in Sections VII.B.7 and VII.B.8 of this proposed rule, the proposed revisions establishing unit-specific backstop daily emissions rates and, for units contributing to assurance level exceedances, secondary unit-specific emissions limitations, would not take effect until the 2024 control period or later.

[295] The EPA notes that transitional provisions similar to the prorating provisions proposed in this section were finalized and implemented under the Revised CSAPR Update.

program regulations, which would be included in the revised Group 3 trading program regulations to represent the states' emissions budgets for the portion of the 2023 control period before the final rule's effective date, and second, the emissions budgets for the 2023 control period established for the states in this rulemaking, which would be included in the revised Group 3 trading program regulations to represent the state's emissions budgets for the portion of the 2023 control period on and after the final rule's effective date. The procedures for determining blended emissions budgets, variability limits and assurance levels, and unit-level allowance allocations would be the same as for the states currently in the Group 3 trading program. Again, all calculations required to determine the prorated emissions budgets and variability limits and the unit-level allocations for the 2023 control period would be carried out as soon as possible after the EPA learns the effective date of a final rule in this rulemaking (which is expected to be approximately 60 days after the date of the final rule's publication in the **Federal Register**). The unit-level allocations for both the 2023 and 2024 control periods would be recorded in facilities' compliance accounts approximately 30 days after the final rule's effective date, as discussed in Section VII.B.9.b of this proposed rule.

The reason for proposing that sources currently in the Group 2 trading program would begin to participate in the Group 3 trading program on May 1, 2023 even if the final rule's effective date is after May 1, 2023, is that it would serve the public interest and greatly aid in administrative efficiency for most elements of the Group 3 trading program—specifically, all elements of the trading program other than the elements designed to establish more stringent emissions limitations for the sources coming from the Group 2 trading program—to apply to the sources starting on May 1, 2023. This would facilitate implementation of the Group 3 trading program in an orderly manner for the entire 2023 ozone season and reduce compliance burdens and potential confusion. Each of the CSAPR trading programs for ozone season NO_X is designed to be implemented over an entire ozone season. Implementing the transition from the Group 2 trading program to the Group 3 trading program in a manner that required the covered sources to participate in the Group 2 trading program for part of the 2023 ozone season and the Group 3 trading program for the remainder of that ozone season would be complex and burdensome for sources. Attempting to address the issue by splitting the Group 2 and Group 3 requirements for these sources into separate years is not a viable approach, because EPA has no legal basis for releasing the transitioning Group 2 sources from the emissions reduction requirements found to be necessary in the CSAPR Update for a portion of the 2023 ozone season, and EPA similarly has no legal basis for deferring implementation of the 2023 emissions reduction requirements found to be necessary under this rule for the transitioning Group 2 sources until 2024. Moreover, the requirements of the current Group 2 trading program and the revised Group 3 trading program for the 2023 control period are substantively identical as to almost all provisions, such that with respect to those provisions, a source will not need to alter its operations in any manner or face different compliance obligations as a consequence of a transition from the Group 2 trading program to the Group 3 trading program. Thus, the EPA believes that no substantive concerns regarding retroactivity arise from transitioning the sources currently in the Group 2 trading program to the Group 3 trading program starting on May 1, 2023, as long as those aspects of the revised Group 3 trading program for the 2023 control period that *do* meaningfully differ from the analogous aspects of the Group 2 trading program—that is, the relative stringencies of the two trading programs, as reflected in the emissions budgets and associated assurance levels—are applied only as of the effective date of the final rule.

In all respects other than prorating the emissions budgets, variability limits and assurance levels, and unit-level allowance allocations, with respect to the sources currently participating in the Group 2 trading program or the Group 3 trading program, the EPA proposes to implement the revised Group 3 trading program for the 2023 control period in a uniform manner for the entire control period. Thus, emissions would be monitored and reported for the entire 2023 ozone season (*i.e.,* May 1, 2023, through September 30, 2023), and as of the allowance transfer deadline for the 2023 control period (*i.e.,* June 1, 2024) each source would be required to hold in its compliance account vintage-year 2023 Group 3 allowances not less than the source's emissions of NO_X during the entire 2023 ozone season. Any efforts undertaken by one of these sources to reduce its emissions during the portion of the 2023 ozone season before the effective date of the rule would aid the source's compliance by reducing the amount of Group 3 allowances that the source would need to hold in its compliance account as of the allowance transfer deadline, increasing the range of options available to the source for meeting its compliance obligations under the revised Group 3 trading program. In the case of the sources that do not currently participate in the Group 2 trading program or the Group 3 trading program, the EPA similarly proposes to implement the revised Group 3 trading program for the 2023 control period in a uniform manner for the entire control period, except that the 2023 control period for these sources may be shorter than the normal 153-day length.

The EPA requests comment on this approach for implementing the Group 3 trading program in a manner that would apply the substantive increases in stringency of the emissions budgets and assurance levels established under the final rule on and after, but not before, the final rule's effective date.

b. Creation of Additional Group 3 Allowance Bank for 2023 Control Period

In the CSAPR Update, where the EPA established the Group 2 trading program and transitioned over 95% of the sources that had been participating in what is now the CSAPR NO_X Ozone Season Group 1 Trading Program (the ''Group 1 trading program'') to the new program, the EPA determined that it was reasonable to establish an initial bank of allowances for the Group 2 trading program by converting almost all allowances banked under the Group 1 trading program at a conversion ratio determined by a formula. In the Revised CSAPR Update, where EPA established the Group 3 trading program and transitioned approximately 55% of the sources that had been participating in the Group 2 trading program to the new program, the EPA similarly determined that it was reasonable to establish an initial bank of allowances for the Group 3 trading program by converting allowances banked under the Group 2 trading program at a conversion ratio determined by a formula, using a conversion procedure that was modified to leave much of the Group 2 allowance bank available for use by the approximately 45% of sources then in the Group 2 trading program that would remain in that program. Any conversion of banked allowances from a previous trading program for use in a new trading program must ensure that implementation of the new trading program will result in NO_X emissions reductions sufficient to address significant contribution by all states that would be participating in the new trading program, while also providing industry certainty (and obtaining an environmental benefit) through continued recognition of the value of saving allowances through early reductions in emissions. EPA's approach to balancing these concerns in the CSAPR Update through the conversion of banked allowances from the Group 1 trading program to the Group 2 trading program was upheld in *Wisconsin* v. *EPA,* see 938 F.3d at 321.

In the current rulemaking, applying the same balancing principle as in the CSAPR Update and the Revised CSAPR Update, the EPA proposes to carry out a further conversion of allowances banked for control periods before 2023 under the Group 2 trading program into allowances usable in the Group 3 trading program in control periods in 2023 and later years. Because the EPA is proposing to transition over 90% of the remaining sources in the Group 2 trading program to the Group 3 trading program—much closer to the situation in the CSAPR Update than the situation in the Revised CSAPR Update—in this rulemaking EPA proposes to apply a conversion procedure similar to the procedure followed in the CSAPR Update. Under the proposed conversion procedure, in the final rule in this rulemaking the EPA would not set a predetermined conversion ratio but instead would set provisions defining the types of accounts whose holdings of Group 2 allowances would be converted to Group 3 allowances and establishing the target amount of new Group 3 allowances that would be created. The proposed conversion date would be August 1, 2023, which is 2 months after the compliance deadline for the 2022 control period under the Group 2 trading program and ten months before the compliance deadline for the 2023 control period under the Group 3 trading program. The actual conversion ratio would be determined as of the conversion date and would be the ratio of the total amount of Group 2 allowances held in the identified types of accounts prior to the conversion to the total amount of Group 3 allowances being created. Consistent with the approach taken in the CSAPR Update, the EPA proposes to define the types of accounts included in the conversion to include all accounts except the facility accounts of sources in states that would remain in the Group 2 trading program.[296] Thus, the accounts whose holdings of Group 2 allowances would be converted to Group 3 allowances would include (1) the facility accounts of all sources in the states transitioning from the Group 2 trading program to the Group 3 trading program, (2) the facility accounts of all sources in the states already participating in the Group 3 trading program, (3) the facility accounts of all sources in any other states not covered by the Group 2 trading program that happen to hold Group 2 allowances as of the conversion date, and (4) all general accounts (that is, accounts that are not facility accounts, including other accounts controlled by source owners as well as accounts controlled by non-source entities such as allowance brokers). Creating the new Group 3 allowances through conversion of previously banked Group 2 allowances would also help preserve the stringency of the Group 2 trading program for the states that remain covered by that trading program at levels consistent with the stringency found to be appropriate to address those states' good neighbor obligations with respect to the 2008 ozone NAAQS in the CSAPR Update.

With respect to setting the target amount of Group 3 allowances that would be created in the conversion process, the EPA proposes to follow the same approach that was used in the Revised CSAPR Update for creation of the initial Group 3 allowance bank. Specifically, the target amount of Group 3 allowances to be created would be computed as the sum of the variability limits for the 2024 control period[297] established in the final rule for the states being transitioned to the Group 3 trading program from the Group 2 trading program, prorated to reflect the portion of the 2023 control period occurring on and after the effective date of the final rule. Based on the amounts of the proposed state emissions budgets and variability limits, the full-season target amount for the conversion would be 18,517 Group 3 allowances. The quantity of banked Group 2 allowances currently held in accounts other than the facility accounts of sources in Iowa and Kansas exceeding the quantity of allowances likely to be needed for 2021 compliance is approximately 110,000 allowances. If the quantities of banked Group 2 allowances did not change between now and the conversion date, and if there was no prorating adjustment, the conversion ratio would be approximately 5.9-to-1, meaning that one Group 3 allowance would be created for every 5.9 Group 2 allowances deducted in the conversion process.[298]

As noted in Section VII.B.11.a of this proposed rule, it is possible that the effective date of this rule will occur after the start of the 2023 ozone season, and provisions are being proposed to ensure that the increased stringency of this rule's state budgets and state assurance levels (*i.e.,* the sums of the budgets and variability limits) would take effect only after the rule's effective date. Consistent with these other procedures, the EPA is proposing to similarly prorate the bank target amount used in the conversion process. For example, if the effective date of the final rule is the eleventh day of the 153-day 2023 ozone season, the full-season initial bank target amount of 18,517 allowances would be prorated to an initial bank target amount of 17,307 allowances.[299] The EPA notes that prorating the bank amount in this manner would not reduce sources' compliance flexibility for the 2023 ozone season, because the amounts of Group 3 allowances that sources would receive for the portion of the 2023 ozone season before the rule's effective date would be based on the current trading program budgets for the 2023 control period before this rulemaking. The current trading program budgets exceed the sources' collective 2021 emissions by approximately 18,600 tons, indicating potentially surplus allowances roughly equal to the full-season bank conversion target amount of 18,517 allowances. Thus, although the prorating procedure would reduce the amount of Group 3 allowances that would be available to sources in the form of an initial bank, the reduction in the quantity of these allowances would be offset by the quantities of Group 3 allowances that would be allocated in excess of sources' recent historical emissions levels for the portion of the ozone season before the final rule's effective date.

As in the CSAPR Update and the Revised CSAPR Update, EPA's overall objective in establishing the target amount for the allowance conversion would be to achieve a total target amount for the bank at a level high enough to accommodate year-to-year

[296] If the proposed expansion of geographic scope for the Group 3 trading program is unchanged in the final rule, the states whose sources would continue to participate in the Group 2 trading program would be Iowa and Kansas.

[297] Similar to the approach taken in the Revised CSAPR Update, because emissions reductions from some of the emissions controls that EPA has identified as appropriate to use in setting budgets are first reflected in the 2024 state budgets rather than the 2023 state budgets, the EPA is proposing to base the bank target amount on the sum of the states' 2024 variability limits rather than the 2023 variability limits.

[298] By comparison, the analogous conversion ratio under the Revised CSAPR Update was 8-to-1.

[299] $18,517 \times (153 - 10) \div 153 = 17,307$.

variability in operations and emissions, as reflected in states' variability limits, but not high enough to allow sources collectively to plan to emit in excess of the collective state budgets. EPA believes that a well-established trading program would be able to function with an allowance bank lower than the full amount of the covered states' variability limits, as discussed in section VII.B.6 with respect to the proposed bank recalibration process that would begin with the 2024 control period. However, EPA also believes there are several compelling reasons in this instance to use a bank target higher than the minimum practicable level.

First, making an allowance bank available for use in the 2023 control period that is somewhat higher than the minimum practicable level would help to address concerns that might otherwise arise regarding the transition to a new set of compliance requirements, for some sources, and the transition to compliance requirements based on revised emissions budgets different from the emissions budgets that the sources had reason to anticipate under previous rulemakings, for the remaining sources. Although the EPA is confident that the emissions budgets being proposed in this rulemaking for the 2023 control period are readily achievable, the EPA also believes that the existence of a somewhat larger allowance bank at this transition point will promote sources' confidence in their ability to meet their 2023 compliance obligations in general and in a liquid allowance market in particular. Second, because the large majority of the remaining Group 2 allowances that would be converted to Group 3 allowances in this rulemaking are held by the sources currently in the Group 2 trading program, while the large majority of the initial bank of Group 3 allowances previously created in the conversion under the Revised CSAPR Update are held by the sources already in the Group 3 trading program, basing the conversion in this rulemaking on a target bank amount set in the same manner as the target bank amount used in the Revised CSAPR Update is expected to result in a less concentrated distribution of holdings of banked Group 3 allowances following the conversion than would be the case if a more stringent target bank amount were used under this rulemaking than was used in the Revised CSAPR Update. A lower concentration of holdings of banked Group 3 allowances would generally be expected to help ensure allowance market liquidity. Third, EPA considers it equitable to treat the sources in the states transitioning from the Group 2 trading program to the Group 3 trading program in this rulemaking roughly similarly to the sources in the states that transitioned between the same two trading programs in the Revised CSAPR Update with respect to the benefit they would receive under the Group 3 trading program for any efforts they may have made to make emissions reductions under the Group 2 trading program beyond the minimum efforts that were required to comply with the emissions budgets under that program. Finally, to the extent that the proposed conversion results in a larger bank of allowances remaining after the 2023 control period than is considered necessary to sustain a well-functioning trading program in subsequent control periods, the excess would be removed from the program in the proposed bank recalibration process that would be implemented starting with the 2024 control period and therefore would not weaken sources' incentives to control emissions on a permanent basis.

The EPA requests comment on the proposal to create additional banked Group 3 allowances through the conversion of Group 2 allowances banked for control periods before 2023.

c. Recall of Group 2 Allowances Allocated for Control Periods After 2022

To maintain the previously established levels of stringency of the Group 2 trading program for the states and sources that remain subject to that program under this proposed rule, the EPA proposes to recall CSAPR NO_X Ozone Season Group 2 allowances equivalent in amount and usability to all vintage year 2023–2024 CSAPR NO_X Ozone Season Group 2 allowances previously allocated to sources in Group 3 states and areas of Indian country and recorded in the sources' compliance accounts. The proposed recall provisions would apply to all sources in jurisdictions newly added to the Group 3 trading program in whose compliance accounts CSAPR NO_X Ozone Season Group 2 allowances for a control period in 2023 or 2024 were recorded, including sources where some or all units have permanently retired or where the previously recorded 2023–2024 allowances have been transferred out of the compliance account. The proposed recall provisions provide a flexible compliance schedule intended to accommodate any sources that have already transferred the previously recorded 2023–2024 allowances out of their compliance accounts and allows Group 2 allowances of earlier vintages to be surrendered to achieve compliance. Like the similar recall provisions finalized in the Revised CSAPR Update, the proposed recall provisions include specifications for how the recall provisions apply in instances where a source and its allowances have been transferred to different parties and for the procedures that the EPA will follow to implement the recall.

Under the Group 2 trading program regulations, each Group 2 allowance is a ''limited authorization to emit one ton of NO_X during the control period in one year,'' where the relevant limitations include the EPA Administrator's authority ''to terminate or limit the use and duration of such authorization to the extent the Administrator determines is necessary or appropriate to implement any provision of the Clean Air Act.'' 40 CFR 97.806(c)(6)(ii). The Administrator proposes to determine that, in order to effectively implement the Group 2 trading program as a compliance mechanism through which states not subject to the Group 3 trading program may continue to meet their obligations under CAA section 110(a)(2)(D)(i)(I) with regard to the 2008 ozone NAAQS, it is necessary to limit the use of Group 2 allowances equivalent in quantity and usability to all Group 2 allowances previously allocated for the 2023–2024 control periods and recorded in the compliance accounts of sources in the newly added Group 3 jurisdictions. The Group 2 allowances that have already been allocated to sources in the newly added Group 3 states for the 2023–2024 control periods and recorded in the sources' compliance accounts represent the substantial majority of the total remaining quantity of Group 2 allowances that have been allocated and recorded for the 2023–2024 control periods and that were not already made subject to recall when other jurisdictions were transferred from the Group 2 trading program to the Group 3 trading program in the Revised CSAPR Update. Because allowances can be freely traded, if the use of the 2023–2024 Group 2 allowances previously recorded in newly added Group 3 sources' compliance accounts (or equivalent Group 2 allowances) were not limited, the effect would be the same as if the EPA had issued to sources in the states that will remain covered by the Group 2 trading program a quantity of allowances available for compliance under the 2023–2024 control periods many times the levels that the EPA determined to be appropriate emissions budgets for these states in the CSAPR Update. Through the use of banked allowances, the excess Group 2 allowances would affect compliance under the Group 2 trading program in control periods after 2024 as well. Continued implementation of the Group 2 trading program at levels of stringency consistent with the levels contemplated under the CSAPR Update therefore requires that the EPA limit the use of the excess allowances, as the EPA is proposing here.

In this rulemaking, the EPA proposes to implement limitations on the use of the excess 2023–2024 Group 2 allowances through requirements to surrender, for each 2023–2024 Group 2 allowance recorded in a newly added Group 3 source's compliance account, one Group 2 allowance of equivalent usability under the Group 2 trading program. The surrender requirements would apply to the owners and operators of the Group 3 sources in whose compliance account the excess 2023–2024 Group 2 allowances were initially recorded. In general, each source's current owners and operators would be required to comply with the surrender requirements for the source by ensuring that sufficient allowances to complete the deductions are available in the source's compliance account by one of two possible deadlines discussed below. However, an exception would be provided if a source's current owners and operators obtained ownership and operational control of the source in a transaction that did not include rights to direct the use and transfer of some or all of the 2023–2024 Group 2 allowances allocated and recorded (either before or after that transaction) in the source's compliance account. The proposed rule provides that in such a circumstance, with respect to the 2023–2024 Group 2 allowances for which rights were not included in the transaction, the surrender requirements would apply to the most recent former owners and operators of the source before any such transactions occurred. Because in this situation a source's former owners and operators might lack the ability to access the source's compliance account for purposes of complying with the surrender requirements, the former owners and operators would instead be allowed to meet the surrender requirements with Group 2 allowances held in a general account.[300]

To provide as much flexibility as possible consistent with the need to limit the use of the excess Group 2 allowances, for each 2023–2024 Group 2 allowance recorded in a Group 3 source's compliance account, the EPA proposes to accept the surrender of either the same specific 2023–2024 Group 2 allowance or any other Group 2 allowance with equivalent (or greater) usability under the Group 2 trading program. Thus, a surrender requirement with regard to a Group 2 allowance allocated for the 2023 control period could be met through the surrender of any Group 2 allowance allocated for the 2023 control period or the control period in any earlier year—in other words, any 2017–2023 Group 2 allowance.[301] Similarly, the surrender requirement with regard to a 2024 Group 2 allowance could be met through the surrender of any 2017–2024 Group 2 allowance.

Owners and operators subject to the surrender requirements could choose from two possible deadlines for meeting the requirements. The first deadline would be 15 days after the effective date of a final rule in this rulemaking.[302] As soon as practicable or after this date, the EPA would make a first attempt to complete the deductions of Group 2 allowances required for each Group 3 source from the source's compliance account. The EPA would deduct Group 2 allowances first to address any surrender requirements for the 2023 control period and then to address any surrender requirements for the 2024 control period. When deducting Group 2 allowances to address the surrender requirements for each control period, EPA would first deduct allowances allocated for that control period and then would deduct allowances allocated for each successively earlier control period. This order of deductions is intended to ensure that whatever Group 2 allowances are available in the account are applied to the surrender requirements in a manner that both maximizes the extent to which all of the source's surrender requirements would be met and also ensures that any Group 2 allowances left in the source's compliance account after completion of all required deductions would be the earliest allocated, and therefore most useful, Group 2 allowances possible. Among the Group 2 allowances allocated for a given control period, The EPA would first deduct allowances that were initially recorded in that account, in the order of recordation, and would then deduct allowances that were transferred into that account after having been initially recorded in some other account, in the order of recordation.

Following the first attempt to deduct Group 2 allowances to address Group 3 sources' surrender requirements, the EPA would send a notification to the designated representative for each such source (as well as any alternate designated representative) indicating whether all required deductions were completed and, if not, the additional amounts of Group 2 allowances usable in the 2023 or 2024 control periods that must be held in the appropriate account by the second surrender deadline of September 15, 2023. Each notification would be sent to the email addresses most recently provided to the EPA for the recipients and would include information on how to contact the EPA with any questions. The EPA proposes that no allocations of Group 3 allowances would be recorded in a source's compliance account until all the source's surrender requirements with regard to 2023–2024 Group 2 allowances have been met. For this reason, the principal consequence to a source of failure to fully comply with the surrender requirements by 15 days after the effective date of a final rule would be that any Group 3 allowances allocated to the units at the source for the 2023 and 2024 control periods that would otherwise have been recorded in the source's compliance account by 30 days after the effective date of a final rule would not be recorded as of that recordation date.

If all surrender requirements of 2023–2024 Group 2 allowances for a source have not been met in EPA's first attempt, the EPA would make a second attempt to complete the required deductions from the source's compliance account (or from a specified general account, in the limited circumstance noted above) as soon as practicable on or after September 15, 2023. The order in which Group 2 allowances are deducted would be the same as described above for the first attempt.

If the second attempt to deduct Group 2 allowances to meet the surrender requirements through deductions from the source's compliance account (or

[300] The EPA is currently unaware of any source that would need to use this flexibility but has included the option in the proposal to address the theoretical possibility of such a situation.

[301] The first control period for the Group 2 trading program was in 2017.

[302] As discussed later in this section and in Section VII.B.9.b, the EPA is proposing to condition recordation of any allocations of Group 3 allowances in a source's compliance account on the source's prior compliance with the proposed recall requirements for Group 2 allowances. The purpose of providing a first deadline for the recall provisions 15 days after a final rule's effective would be to ensure that sources have an early opportunity to comply with the recall provisions in order to be eligible to have allocations of Group 3 allowances recorded in their accounts as proposed 30 days after the final rule's effective date. Because the vast majority of sources subject to the proposed recall provisions already hold sufficient Group 2 allowances to comply with the recall provisions, the EPA anticipates that the sources would easily be able to comply with the proposed first recall deadline.

from a specified general account) is unsuccessful for a given source, the EPA proposes that as soon as practicable on or after November 15, 2023, to the extent necessary to address the unsatisfied surrender requirements for the source, the EPA would deduct the 2023–2024 Group 2 allowances that were initially recorded in the source's compliance account from whatever accounts the allowances are held in as of the date of the deduction, except for any allowances where, as of April 1, 2022, no person with an ownership interest in the allowances was an owner or operator of the source, was a direct or indirect parent or subsidiary of an owner or operator of the source, or was directly or indirectly under common ownership with an owner or operator of the source.[303] Before making any deduction under this provision, the EPA would send a notification to the authorized account representative for the account in which the allowance is held and would provide an opportunity for submission of objections concerning the data upon which the EPA is relying. In EPA's view, this provision would not unduly interfere with the legitimate expectations of participants in the allowance markets because the provision would not be invoked in the case of any allowance that was transferred to an independent party in an arms-length transaction before EPA's intent to recall 2023–2024 Group 2 allowances became widely known. The provision would apply only to a Group 2 allowance that, as of April 1, 2022, was still controlled either by the owners and operators of the source in whose compliance account it was initially recorded or by an entity affiliated with such an owner or operator. The EPA believes that by April 1, 2022, all market participants will have had ample opportunity to become informed of the proposed rule provisions to recall 2023–2024 Group 2 allowances recorded in Group 3 sources' compliance accounts, particularly since the EPA implemented a closely analogous recall of Group 2 allowances in the Revised CSAPR Update.[304]

The EPA proposes that failure of a source's owners and operators to comply with the surrender requirements would be subject to possible enforcement as a violation of the CAA, with each allowance and each day of the control period constituting a separate violation.

To eliminate any possible uncertainty regarding the amounts of Group 2 allowances allocated for the 2023–2024 control periods (or earlier control periods) that the owners and operators of each Group 3 source would be required to surrender under the recall provisions, the EPA has prepared a list of the sources in the proposed additional Group 3 states and areas of Indian country in whose compliance accounts allocations of 2023–2024 Group 2 allowances were recorded, with the amounts of the allocations recorded in each such compliance account for the 2023 and 2024 control periods. An additional list shows, for each newly added Group 3 source, the specific Group 2 allowances (batched by serial number) allocated for each control period and recorded in the source's compliance account and indicates whether, as of December 31, 2021, that batch of allowances was held in the source's compliance account, in an account believed to be partially or fully controlled by a related party (*i.e.,* an owner or operator of the source or an affiliate of an owner or operator of the source), or in an account believed to be fully controlled by independent parties. The lists are in a spreadsheet titled, ''Recall of Additional CSAPR NO_X Ozone Season Group 2 Allowances'', available in the docket for this proposed rule. After the first and second surrender deadlines, the EPA intends to update the lists to indicate for each Group 3 source whether the surrender requirements for the source under the recall provisions have been fully satisfied. The EPA would post the updated lists on a publicly accessible website to ensure that all market participants have the ability to determine which specific 2023–2024 Group 2 allowances initially recorded in any given Group 3 source's compliance account do or do not remain subject to potential deduction to address the source's surrender requirements under the recall provisions.

The EPA requests comment on the proposal to recall Group 2 allowances equivalent in quantity and usability to the Group 2 allowances previously issued for the 2023 and 2024 control periods and recorded in the compliance accounts of sources in jurisdictions being newly added to the Group 3 trading program in this proposed rule.

12. Conforming Revisions to Other Regulations

As noted in Section VII.B.1.a of this proposed rule, in addition to the Group 3 trading program, EPA currently administers five other CSAPR trading programs, all of which have provisions that in most respects parallel the provisions of the Group 3 trading program.[305] The EPA also administers the Texas SO_2 Trading Program, whose provisions parallel the provisions of the CSAPR trading programs to a somewhat lesser extent.[306] In this rulemaking, in addition to the proposed revisions to the Group 3 trading program, the EPA is proposing a small number of conforming revisions to the other CSAPR trading programs and/or the Texas SO_2 Trading Program to maintain consistency across the regulations for the various trading programs to the extent possible.

The first set of proposed conforming revisions concerns the use of the term ''Indian country'' in the allowance allocation provisions of the regulations for all the CSAPR trading programs. As discussed in Section VII.B.9.a of this proposed rule, to reflect the D.C. Circuit's holding in *ODEQ* v. *EPA* that states have initial CAA implementation planning authority in non-reservation areas of Indian country until displaced by a demonstration of tribal jurisdiction over such an area, the EPA is proposing to revise the allowance allocation provisions in the Group 3 trading program regulations so that, instead of distinguishing between the sets of units within a given state's borders that either are not or are in Indian country, the revised regulations would distinguish between (1) the set of units within the state's borders that are not in Indian country or are in areas of Indian country covered by the state's CAA implementation planning authority and (2) the set of units within the state's borders that are in areas of Indian country not covered by the state's CAA implementation planning authority. For the same reasons stated in Section VII.B.9.a of this proposed rule for the

[303] The proposed provision under which the EPA would not deduct Group 2 allowances transferred to unrelated parties before April 1, 2022 from the transferees' accounts would not relieve the source to which the Group 2 allowances were originally allocated from the obligation to comply with the recall requirements. Specifically, the source would be required to comply with the recall requirements by obtaining and surrendering other Group 2 allowances.

[304] Even before publication of the proposed rule, the EPA posted information on its websites to notify market participants that a pending rulemaking could have consequences for the value and usability of Group 2 allowances. The posted locations included the electronic portal that authorized account representatives use to enter allowance transfers for recordation by the EPA in the Allowance Management System. Additionally, the EPA emailed a notice identifying the possibility of such consequences to the representatives for all Allowance Management System accounts.

[305] The regulations for the Group 3 Trading Program are at 40 CFR 97, subpart GGGGG. The regulations for the other five CSAPR trading programs are at 40 CFR part 97, subparts AAAAA, BBBBB, CCCCC, DDDDD, and EEEEE.

[306] The regulations for the Texas SO_2 Trading Program are at 40 CFR part 97, subpart FFFFF.

Group 3 trading program, the EPA proposes to make revisions to the allowance allocation provisions in the regulations for all the other CSAPR trading programs establishing the same substantive distinction among the sets of units within each state's borders. The specific regulatory provisions that would be affected are identified in Section X of this proposed rule. The EPA is unaware of any currently operating units that would be affected by this proposed revision to the regulations for the other CSAPR trading programs.

The second set of proposed conforming revisions concerns the schedule for recording allocations of allowances to existing units. To maintain consistency with the provisions of the revised Group 3 Trading Program to the extent possible, the EPA proposes to revise the regulations for each of the other five CSAPR trading programs and the Texas SO_2 Trading Program to reflect whatever revised schedule for recording most allowance allocations the EPA may adopt for the revised Group 3 trading program in a final rule in this rulemaking. The proposed revisions to the recordation deadlines would affect only the timing of recordation, not the amounts of allowances allocated to and recorded for any source for any control period.

The effect of the proposed revisions would be to establish a new common recordation schedule for all the CSAPR trading programs and the Texas SO_2 Trading Program. Assuming the common schedule adopted is the specific schedule proposed for the Group 3 trading program in Section VII.B.9 of this proposed rule, allocations from the portion of each state emissions budget under each program not reserved in a set-aside would be recorded by July 1 of the year immediately preceding the year of the relevant control period. Under the current regulations before the proposed revisions, the equivalent recordation deadline is July 1 of the year three years before the year of the relevant control period. Relatedly, the EPA also proposes to revise the deadline for states to submit any state-determined allocations to the EPA under each trading program to June 1 of the year immediately preceding the year of the relevant control period, instead of June 1 of the year three years before the year of the relevant control period.[307]

This EPA believes that revising the recordation schedules as proposed to establish a new common recordation schedule for the affected trading programs would make the programs procedurally more consistent, generally reducing the time and cost expended by sources to understand and comply with multiple trading programs. Greater consistency across the various programs would also support greater administrative efficiency by the EPA and by states that elect to determine allowances allocations under the various programs. In addition, by reducing the number of future control periods for which allowances are recorded, the proposed revisions would reduce the likelihood that the EPA might need to recall already-recorded allowances as part of a transition for some sources to new regulatory requirements in a future rulemaking. The EPA has implemented such a recall in the Revised CSAPR Update and has proposed to implement a similar recall in this rulemaking.

Finally, the EPA believes that revising the recordation schedules for the other CSAPR trading programs and the Texas SO_2 Trading Program as proposed would not adversely impact allowance market liquidity. Allowances issued for control periods through 2024 under each of these programs were recorded by July 1, 2020. As of December 2021, although recorded private transfers of earlier vintage allowances usable for 2021 compliance have been increasing in advance of the upcoming June 1, 2022, compliance deadline for the 2021 control periods, few allowances recorded for the 2023 or 2024 control periods (or even the 2022 control period) under any of the programs have been transferred out of the accounts in which they were initially recorded, except as needed to comply with the recall of certain allowances under the Revised CSAPR Update. Moreover, most of the recorded transfers of allowances issued for 2022, 2023, and 2024 have been between accounts controlled by the same entity, corporate affiliates, or other related entities (such as unit co-owners) rather than between accounts controlled by unrelated parties. The EPA therefore believes there would have been little effect on arms-length allowance market activity in these programs if the proposed revised recordation schedule had already been in effect and the allowances for 2023 and 2024 consequently had not yet been recorded.

Further details on the specific regulatory provisions that would be affected by the proposed revisions to allowance allocation recordation schedules are provided in Section X of the proposed rule.

The EPA requests comment on the proposed revision to the definition of ''Indian country'' under the CSAPR NO_X Annual, NO_X Ozone Season Group 1, SO_2 Group 1, SO_2 Group 2, and NO_X Ozone Season Group 2 Trading Programs and the proposed revisions to the allowance allocation recordation deadlines under the CSAPR NO_X Annual, NO_X Ozone Season Group 1, SO_2 Group 1, SO_2 Group 2, and NO_X Ozone Season Group 2 Trading Programs and the Texas SO_2 Trading Program.

C. Regulatory Requirements for Non-EGUs

The EPA is proposing that the FIPs for 23 of the states covered in this proposed rule will include new emissions limitations on emissions units in seven non-EGU industries that EPA finds (as discussed in Section VI of this proposed rule) to be significantly contributing to nonattainment or interfering with maintenance in other states.

In order to achieve the necessary non-EGU emissions reductions for the 23 states, the EPA proposes emissions limitations for the most impactful units in the relevant industries that are achievable with the control technologies identified in the Step 3 analysis. The EPA is proposing a direct control approach with rate-based limits, production-based limits, and work practice standards set on a uniform basis for the different segments of non-EGU emissions units using applicability criteria based on size and type of unit and, in some cases, emissions thresholds. The EPA believes this approach can achieve the requisite level of emissions reductions from the covered units through the assignment of emissions limits that are achievable across the entire segment. The EPA believes that establishing emissions limits for emissions units based on size and type of unit and, in some cases, emissions thresholds, will achieve the necessary reductions without requiring a unit-by-unit assessment.[308] By

[307] The regulations for the various programs already establish a common recordation schedule for the portion of each state emissions budget set aside for possible allocation to new units—namely, by May 1 of the year after the year of the relevant control period. The related deadline for states to submit any state-determined allocations of these allowances to the EPA under each program is April 1 of the year after the year of the relevant control period.

[308] If an emissions unit installs SCR or SNCR to meet an emissions limit in response to the proposed FIP that would be a physical change under new source review (NSR) and lead to an assessment of potential emissions changes. If the installation of SCR results in an emissions increase that exceeds the thresholds in the NSR regulations for one or more regulated NSR pollutants, including the

establishing uniform emissions limits for categories of units rather than on a unit-by-unit basis, the EPA can also ensure that any new source of emissions constructed after this proposed rulemaking are also subject to the emissions limits identified later (*see* Section IV.B.1.d of this proposed rule).

The EPA recognizes that the numerous variables that contribute to differences in units' emissions rates may complicate development of limits for groups of units as large as those addressed in this proposed rule. For each emissions source category, the EPA considered the range of emissions limits that currently apply to these sources under other CAA programs, such as RACT, NSPS, NESHAP, and OTC model rules, to develop an emissions limit that should be achievable by all sources after installing the controls identified in the Step 3 analysis. For a detailed discussion of the technical bases for EPA's proposed requirements for non-EGU emissions units, see the Non-EGU Sectors TSD.

The EPA is proposing that the emissions limits and compliance requirements for non-EGUs will apply only during the ozone season (which runs annually from May–September). This is consistent with EPA's prior practice in federal actions to eliminate significant contribution of ozone in the 1998 NO_X SIP Call, CAIR, CSAPR, CSAPR Update, and the Revised CSAPR Update. EPA is seeking comment on whether non-EGU sources would run controls that would be installed as a result of this proposed FIP year-round (*i.e.,* will some source categories run their controls year-round due to the nature of those controls?).

In addition, the EPA proposes to apply the FIP requirements to all existing emissions units and any future emissions units constructed after the promulgation of a final rule. Further, the non-EGU emissions limits and compliance requirements will apply in all 23 states (and, as discussed in Section IV.C.2 of this proposed rule, in areas of Indian country within the borders of those states), even if some of those states do not currently have emissions units in a particular source category. This approach will ensure that all new sources constructed in any of the 23 states will be subject to the same regulatory requirements as applied for the existing units under this proposed rule. This will also mitigate any potential incentive to move production from an existing non-EGU source in one linked state to a new non-EGU source of the same type but lacking the relevant emissions control requirements in another linked state.

At this time, this EPA is not proposing to include non-EGUs in the trading program described in this proposed rule. If EPA were to include non-EGUs in the trading program, we would require monitoring and reporting of hourly mass emissions in accordance with 40 CFR part 75 as we have required for all trading programs. Monitoring and reporting under part 75 include CEMS (or an approved alternative method), rigorous initial certification testing, and periodic quality assurance testing thereafter, such as relative accuracy test audits and daily calibrations. This type of consistent and accurate measurement of emissions is necessary to ensure each allowance actually represents one ton of emissions and that one ton of reported emissions from one source would be equivalent to one ton of reported emissions from another source. *See* 75 FR 45325 (August 2, 2010). Moreover, these monitoring requirements generally would need to be in place for at least one full ozone season to establish baseline data before it would be appropriate to rely on a trading program as the mechanism to achieve the required emissions reductions. Therefore, at this time, the EPA believes that applying unit-level emissions limitations on non-EGU emissions units rather than constructing an emissions trading regime is more administratively feasible and more easily implementable at the source level, and it will effectively eliminate each state's significant contribution without the need for establishing a new emissions trading program.

The EPA is proposing to require electronic reporting for all seven non-EGU industries. Specifically, owners and operators of affected units must submit electronic copies of required performance test reports, performance evaluation reports, quarterly and semi-annual reports, and excess emissions reports through EPA's Central Data Exchange (CDX) using the Compliance and Emissions Data Reporting Interface (CEDRI). The EPA is proposing to require that performance test results collected using test methods that are supported by EPA's Electronic Reporting Tool (ERT) as listed on the ERT website [309] at the time of the test be submitted in the format generated through the use of the ERT or an electronic file consistent with the xml schema on the ERT website, and that other performance test results be submitted in portable document format (PDF) using the attachment module of the ERT. Similarly, the EPA is proposing to require that performance evaluation results of CEMS measuring relative accuracy test audit (RATA) pollutants that are supported by the ERT at the time of the test be submitted in the format generated through the use of the ERT or an electronic file consistent with the xml schema on the ERT website, and that other performance evaluation results be submitted in PDF using the attachment module of the ERT. In addition, the EPA is proposing to require that quarterly and semi-annual reports and excess emissions reports be submitted in PDF uploaded in CEDRI.

The EPA is proposing to allow for an extension of time to file a report where an owner or operator demonstrates that it cannot meet the reporting deadline for reasons outside of its control. Specifically, the EPA has identified two broad circumstances under which the EPA may grant a request for an extension of time to file an electronic report. These circumstances are (1) outages of EPA's CDX or CEDRI which preclude an owner or operator from accessing the system and submitting required reports and (2) *force majeure* events, which are defined as events that will be or have been caused by circumstances beyond the control of the affected facility, its contractors, or any entity controlled by the affected facility that prevent an owner or operator from complying with the requirement to submit a report electronically. Examples of *force majeure* events are acts of nature, acts of war or terrorism, or equipment failure or safety hazards beyond the control of the facility. In both circumstances, the decision to grant an extension of time to report is within the discretion of the Administrator, and reporting should occur as soon as possible.

Electronic submittal of required reports will increase the usefulness of the data contained in those reports, is in keeping with current trends in data availability and transparency, will further assist in the protection of public health and the environment, will improve compliance by facilitating the ability of regulated facilities to demonstrate compliance with requirements and by facilitating the ability of the EPA to assess and determine compliance, and will ultimately reduce burden on regulated facilities and the EPA. Electronic reporting also eliminates paper-based, manual processes, thereby saving time and resources, simplifying data entry, eliminating redundancies, minimizing

netting analysis, the changes would trigger the applicability of NSR.

[309] *https://www.epa.gov/electronic-reporting-air-emissions/electronic-reporting-tool-ert.*

data reporting errors, and providing data quickly and accurately to the affected facilities, air agencies, EPA, and the public. Moreover, electronic reporting is consistent with EPA's plan [310] to implement Executive Order 13563 and is in keeping with EPA's agency-wide policy [311] developed in response to the White House's Digital Government Strategy.[312]

The EPA notes that no emissions standard or other requirement established for non-EGUs in these FIPs may be interpreted, construed, or applied to diminish or replace the requirements of any emissions limitation or other applicable requirement established by the Administrator pursuant to other CAA authority or a standard issued under State authority.

1. Pipeline Transportation of Natural Gas

Applicability

The EPA is proposing to establish regulatory requirements for the Pipeline Transportation of Natural Gas industry that apply to stationary, natural gas-fired, spark ignited reciprocating internal combustion engines (''stationary SI engines'') within these facilities that have a maximum rated capacity of 1,000 horsepower (hp) or greater. Based on our review of the potential emissions from stationary SI engines, we find that use of a maximum rated capacity of 1,000 hp reasonably approximates the selection of 100 tpy used within the non-EGU screening assessment. Therefore, stationary SI engines subject to the proposed rule requirements of this section are those found within any of the 23 covered states with non-EGU emissions reduction obligations that are within the Pipeline Transportation of Natural Gas industry and have a maximum rated capacity of 1,000 hp or greater.

Emissions Limitations and Rationale

In developing the emissions limits for the Pipeline Transportation of Natural Gas industry, EPA reviewed RACT NO_X rules, air permits, and OTC model rules. While some permits and rules express engine emissions limits in parts per million by volume (pmmv), the majority of rules and source-specific requirements express the emissions limits in grams per horsepower per hour (g/hp-hr). The EPA has historically set emissions limits for these types of engines using g/hp-hr and finds that method appropriate for this proposed FIP as well.

Based on the available information for this industry, applicable State and local air agency rules, and active air permits issued to sources with similar engines, the EPA is proposing the following emissions limits for stationary SI engines in the covered states:

TABLE VII.C–1—SUMMARY OF PROPOSED NO_X EMISSIONS LIMITS FOR PIPELINE TRANSPORTATION OF NATURAL GAS

Engine type and fuel	Proposed NO_X emissions limit	Additional information
Natural Gas Fired Four Stroke Rich Burn	1.0 g/hp-hr	Limits reviewed ranged between 0.2 and 3.0 g/hp-hr.
Natural Gas Fired Four Stroke Lean Burn	1.5 g/hp-hr	Limits reviewed ranged between 0.5 and 3.0 g/hp-hr.
Natural Gas Fired Two Stroke Lean Burn	3.0 g/hp-hr	Limits reviewed ranged between 0.5 and 3.0 g/hp-hr.

With regard to four stroke rich burn engines, the EPA is proposing an emissions limit of 1.0 g/hp-hr. This limit is designed to be achievable by installing Non-Selective Catalytic Reduction (NSCR) on existing four stroke rich burn engines, as identified in the non-EGU screening assessment. Sources are free to install another control technology besides NSCR as long as the unit is still able to meet the emissions limit. In particular for four stroke rich burn engines, NSCR can be an effective control technology due to the low oxygen percentage in the exhaust. Efficient operation of the catalyst in NSCR requires the engine exhaust gases contain no more than 0.5 percent oxygen, which makes rich burn engines uniquely suitable to NCSR. Given that NSCR can achieve NO_X reductions of 90 to 99 percent, the EPA believes an emissions limit of 1.0 g/hp-hr should be readily achievable by all four stroke rich burn engines subject to this proposed rulemaking. The EPA is taking comment on whether a lower emissions limit is more appropriate since even an assumed reduction of 95 percent would result in most engines being able to achieve an emissions rate of 0.5 g/hp-hr. However, at this time, the EPA does not have the information necessary to determine if a lower emissions limit is achievable for the four stroke rich burn engines subject to the proposed rulemaking, and therefore, the EPA is proposing an emissions limit of 1.0 g/hp-hr.

With regard to four stroke lean burn engines, the EPA is proposing an emissions limit of 1.5 g/hp-hr. This limit is designed to be achievable by installing SCR on existing four stroke lean burn engines. Sources are free to install another control technology with or without SCR as long as the unit is still able to meet the emissions limit. For example, it might be more cost effective on an ongoing basis for some four stroke lean burn engines to install layered combustion controls alone or along with SCR to achieve the necessary emissions reductions. Information available to the EPA suggests that some four stroke lean burn engines can achieve 90% reductions from layered combustion controls alone, such as turbochargers and inter-cooling, pre-chamber ignition or high energy ignition, improved fuel injection control, air/fuel ratio control.[313] Independent of unit specific considerations, the EPA believes that four stroke lean burn engines subject to this proposed FIP can achieve an emissions limit of 1.5 g/hp-hr with the installation and operation of SCR or other control technologies at the marginal cost threshold of $7,500 per

[313] Ozone Transport Commission, *Technical Information Oil and Gas Sector Significant Stationary Sources of NO_X Emissions,* 35–39, October 17, 2012.

ton identified in the non-EGU screening assessment. While a lower emissions limit may be achievable with SCR for some four stroke lean burn engines, the achievability of those lower limits may depend on engine age and come with increased costs not accounted for in this proposed rule. The EPA is seeking comment on whether a lower and higher emissions limit is appropriate for these units.

For two stroke lean burn engines, the EPA is currently proposing an emissions limit of 3.0 g/hp-hr. This limit is designed to be achievable by retrofitting existing two stroke lean burn engines with layered combustion to achieve this emissions limit. Sources are free to install another control technology besides layered combustion as long as the unit is still able to meet the emissions limit. As identified in the non-EGU screening assessment, the EPA believes that layered combustion controls, such as improved airflow, improved fuel to air mixing, improved ignition, and modern engine electronic controls can be achieved on two stroke engines at the marginal cost threshold of $7,500 per ton. With these types of controls, the information currently available to the EPA indicates that the amount of achievable emissions reductions is unit specific and can range from a 60 to 90 percent reduction in NO_X emissions. The EPA estimates that existing uncontrolled two stroke lean burn engines would need to reduce emissions by about 80 percent to comply with a 3.0 g/hp-hr emissions limit. While some RACT and model rules reviewed contained more stringent emissions limits for two stroke lean burn engines, the EPA does not have information adequate to conclude that the two stroke lean burn engines across all 23 states can meet a lower limit. Further, some information available supports a finding that an emissions limit below 3.0 g/hp-hr might not be achievable with layered combustion controls alone for some units, and those units would require additional controls beyond our cost threshold.[314] Therefore, the EPA is proposing an emissions limit of 3.0 g/bhp-hr for two stroke engines. The EPA is seeking comment on whether a lower emissions limit would be achievable with layered combustion alone for the sources covered by this FIP. Further, the EPA is seeking comment on whether additional control technology could be installed on these sources at or below the marginal cost threshold to achieve a lower emissions rate.

Compliance Assurance Requirement

The EPA is proposing to require stationary SI engines subject to this proposed FIP to conduct semi-annual performance testing in accordance with 40 CFR 60.8 to ensure that the engine is meeting the NO_X emissions limit. The EPA is proposing that affected engines then monitor and record hours of operation and fuel consumption to calculate ongoing compliance with the applicable emissions limit. In addition, the EPA is proposing that affected engines would use continuous parametric monitoring systems (CPMS) to ensure that the NO_X emissions limit is being met at all times. For example, engines utilizing layered combustion controls would need to monitor and record temperature, air to fuel ratio, and other parameters as appropriate to ensure that combustion conditions are optimized to reduce NO_X emissions and assure compliance with the emissions limit. For engines using SCR or NSCR, the EPA is proposing that source monitor and record parameters such as inlet temperature to the catalyst and pressure drop across the catalyst.

The EPA is seeking comment on whether it is feasible or appropriate to require affected engines to be equipped with continuous emissions monitoring systems (CEMS) to measure and monitor the NO_x emissions instead of conducting performance tests on a semiannual basis.

2. Cement and Concrete Product Manufacturing

Applicability

The EPA is proposing to establish regulatory requirements for the Cement and Concrete Product Manufacturing source category that apply to emissions units (kilns) that directly emit or have the potential to emit 100 tpy or more of NO_X. Further, the EPA is proposing emissions limits based on type of unit to ensure that the necessary NO_X emissions reductions occur. The EPA is seeking comment on whether it should set an applicability threshold based on a unit's design production capacity rather than an emissions threshold.

Emissions Limitations and Rationale

In developing the emissions limits for the Cement and Concrete Manufacturing industry, the EPA reviewed RACT NO_X rules, air permits, and consent decrees. These rules and source-specific requirements most commonly express the emissions limits for this industry in terms of mass of pollutant emitted (pounds) per kiln's clinker output (tons), *i.e.,* pounds of NO_X emitted per ton of clinker produced. A regulated entity routinely monitors and keeps track of its clinker output as it pertains to a kiln design capacity and the plant's production. Therefore, the EPA believes that this form of NO_X emissions limit is effective, practicable and convenient to record and report to an air agency.

In determining the averaging time for the limit, the EPA considered the NSPS for Portland Cement Plants at 40 CFR part 60, subpart F. Section 60.62(a)(3) of this subpart establishes a 30-operating day rolling average period for the NO_X emitted per ton of clinker produced and further states that an operating day includes all valid data obtained in any daily 24-hour period during which the kiln operates and excludes any measurements made during the daily 24-hour period when the kiln was not operating. In addition, 40 CFR 60.44b(i) requires that compliance with the applicable NO_X emissions limit be determined on a 30-day rolling average basis. The EPA is proposing to require a 30-operating day rolling average period as the averaging time frame for this particular industry. The proposed averaging timeframe is consistent with the longstanding national technology-based NSPS for this industry at 40 CFR part 60, subpart F. Furthermore, an air agency may choose to require an averaging period shorter than a 30-operating day rolling average in air permit(s) issued to these plants. The EPA finds that a 30-operating day rolling average period provides a reasonable balance between short term (hourly or daily) and long term (annual) averaging periods, while being flexible and responsive to fluctuations in operations and production.

Based on the available information for this industry, applicable State and local air agency rules, and active air permits or enforceable orders issued to affected cement plants, the EPA is proposing the following emissions limits for cement kilns:

[314] Ozone Transport Commission, *Technical Information Oil and Gas Sector Significant Stationary Sources of NO_X Emissions* at 24–25.

TABLE VII.C–2—SUMMARY OF PROPOSED NO_X EMISSIONS LIMITS FOR KILN TYPES IN CEMENT AND CONCRETE PRODUCT MANUFACTURING

Kiln type	Proposed NO_X emissions limit (lb/ton of clinker)	Additional information
Long Wet	4.0	Limits reviewed ranged between 3.88–5.2; one State rule allows as high as 6.0; with addition of a post combustion NO_X control the upper range could be reduced significantly.
Long Dry	3.0	Limits reviewed showed 5.1; with addition of post combustion NO_X control the limit could be reduced significantly; limit of 3.0 would achieve a 41% reduction in NO_X emissions.
Preheater	3.8	Limits reviewed ranged between 1.5–3.44; limit of 3.8 is consistent with 30 TAC 117.3110(a)(3) and 35 IAC 217.224(a).
Precalciner	2.3	Requires post combustion NO_X control; consistent with permit A0017 for Lehigh Southwest Cement Company issued on May 5, 2020 by the Bay Area Air Quality Management District.
Preheater/Precalciner	2.8	Limits reviewed ranged between 1.8–3.4; limit of 2.8 is consistent with 30 TAC 117.3110(a)(4); Mitsubishi Cement Corporation Lucerne Valley Federal Operating Permit 11800001 issued by the Mojave Desert Air Quality Management District (MDAQMD) June 18, 2020; MDAQMD Rule 1161 (C)(2); and Illinois 35 IAC 217.224(a).

Although the EPA is proposing NO_X emissions limits based on the specific kiln types listed in Table VII.C–2, to provide operational flexibility the EPA is also proposing a source cap limit expressed in tons per day (tpd) of NO_X for each individual cement plant according to the following equation.

$$CAP2015\ Ozone\ Transport = \frac{(KW\ x\ NW) + (KD\ x\ ND)}{(2000\frac{pounds}{ton}\ x\ 365\frac{days}{year})}$$

Where:

CAP2015 Ozone Transport = total allowable NO_X emissions from all cement kilns located at one cement plant, in tons per day, on a 30-operating day rolling average basis;

KD = 1.7 pounds NO_X per ton of clinker for dry preheater-precalciner or precalciner kilns;

KW = 3.4 pounds NO_X per ton of clinker for long wet kilns;

ND = the average annual production in tons of clinker plus one standard deviation for the three most recent calendar years from all dry preheater-precalciner or precalciner kilns located at one cement plant; and

NW = the average annual production in tons of clinker plus one standard deviation for the three most recent calendar years from all long wet kilns located at one cement plant.

An affected cement plant will need to comply with both the source cap limit and the specific NO_X emissions limits assigned to its individual kiln type(s). The EPA notes that the above source cap would be calculated and assigned to operating kilns in a particular plant. That is, the total allowable NO_X emissions in tpd from one plant cannot be traded with another plant, regardless of these plants' control of ownership or operator's status, or regardless of these plants' proximity to each other or their location.

The EPA is soliciting comment on whether it is feasible or appropriate to phase out and retire existing long wet kilns in the affected states and to replace them with more energy efficient and less emitting units like preheater/precalciner installations. The EPA is also requesting comment on the time needed to complete such a task. It has been shown that such kilns replacements (preheater/precalciner kilns), when equipped with post-combustion NO_X control devices such as SNCR, are capable of meeting NO_X emissions limit of 1.5 lb/ton of clinker on a 30-operating day basis. For this reason, the EPA proposes to find that conversion from long wet kilns to preheater/precalciner installations is generally feasible. Given that long wet kilns are less energy efficient and generally emit more NO_X than other kiln types, conversion to preheater/precalciner installations would be the most effective method of NO_X reduction (per ton of clinker produced).

Additionally, EPA is soliciting comments on whether it is feasible or appropriate to require sources with existing preheater/precalciner kilns in the affected states that currently utilize low NO_X burners, combustion controls, staged combustion, or mid-kiln firing to add and operate a post combustion control device like SNCR or SCR to further improve their NO_X removal efficiency and lower NO_X emissions to 1.95 lb/ton of clinker or less. The EPA is also requesting comments on the time needed to complete such an addition.

We note that the EPA previously stated that it expects that the controls for cement kilns would take at least 2 years to install on a sector-wide basis across the 12-state region affected by the Revised CSAPR Update.[315]

Compliance Assurance Requirements

The EPA is proposing that performance tests be conducted on a semiannual basis. Such tests shall be conducted in conformance with the requirements of 40 CFR 60.8. Stack tests will need to conform with the Test Methods and Procedures in 40 CFR 60 appendix A, or other EPA-approved (federally enforceable) test methods and procedures.

The EPA is soliciting comments on whether it is feasible or appropriate to require affected units (kilns) to be equipped with CEMS to measure and monitor the NO_X concentration (emissions level) instead of conducting performance tests on semiannual basis.

We are also soliciting comment on whether it is appropriate for the affected units (kilns) to use CPMS instead of CEMS to monitor the NO_X concentration (emissions level). We note that CPMS, also called parametric monitoring, measures a parameter (or multiple parameters) as a key indicator of system performance. The parameter is generally an operational parameter of the process

[315] 85 FR 68999 (October 30, 2020).

or the air pollution control device (APCD) that is known to affect the emissions levels from the process or the control efficiency of the APCD. Examples of parametric monitoring include kiln feed rate, clinker production rate, fuel type, fuel flow rate, specific heat consumption, secondary air temperature, kiln feed-end temperature, preheater exhaust gas temperature, induced draught fan pressure drop, kiln feed-end percentage oxygen, percentage downcomer oxygen, primary air flow rate, ammonia feed rate and slippage.

3. Iron and Steel Mills and Ferroalloy Manufacturing

Applicability

The EPA is proposing to establish regulatory requirements for the Iron and Steel Mills and Ferroalloy Manufacturing source category that apply to emissions units that directly emit or have the potential to emit 100 tpy or more of NO_X and to facilities containing two or more such units that collectively emit or have the potential to emit 100 tpy or more of NO_X. The EPA is setting emissions limits based on type of unit to ensure that the necessary emissions reductions occur across all units of the same type. The EPA is seeking comment on whether it should set an applicability threshold based on a unit's production capacity rather than an emissions threshold.

Emissions Limitations and Rationale

In developing the emissions limits for the Iron and Steel and Ferroalloy Manufacturing industry, the EPA reviewed RACT NO_X rules, NESHAP rules, air permits and related emissions tests, technical support documents, and consent decrees. These rules and source-specific requirements most commonly express the emissions limits for this industry in terms of mass of pollutant emitted (pounds) per operating hour (hours) (*i.e.,* pounds of NO_X emitted per production hour), pounds per energy unit (*i.e.,* million British thermal unit (mmBtu)), or pounds of NO_X per ton of steel produced. A regulated entity routinely monitors and keeps track of its production in terms of tons of steel produced per hour (heat rate) as it pertains to the facility's rate of iron and steel production. Depending on the type of unit and industry practice, the EPA is proposing rate-based emissions limits in the form of lb/mmBtu, production-based limits in the form of lb/ton, and work practice standards.

In determining the averaging times for the limits, EPA initially reviewed the NESHAP for Iron and Steel Foundries codified at 40 CFR part 63 subpart EEEEE, the NESHAP for Integrated Iron and Steel manufacturing facilities codified at 40 CFR part 63 subpart FFFFF, the NESHAP for Ferroalloys Production: Ferromanganese and Silicomanganese codified at 40 CFR part 63 subpart XXX, and the NESHAP for Ferroalloys Production Facilities codified at 40 CFR part 63 subpart YYYYYY. EPA also reviewed various RACT NO_X rules from states located within the OTR, several of which have chosen to implement OTC model rules and recommendations. Based on this information, the EPA is proposing to require a 30-operating day rolling average period as the averaging time frame for this particular industry. The EPA finds that a 30-operating day rolling average period provides a reasonable balance between short term (hourly or daily) and long term (annual) averaging periods, while being flexible and responsive to fluctuations in operations and production.

Based on the available information for this industry, applicable federal and state rules, and active air permits or enforceable orders issued to affected facilities in the iron and steel and ferroalloy manufacturing industry, the EPA proposes the following emissions limits:

TABLE VII.C–3—SUMMARY OF PROPOSED NO_X EMISSIONS LIMITS FOR IRON AND STEEL AND FERROALLOY EMISSIONS UNITS

Emissions unit	Proposed NO_X emissions standard or requirement (lbs/hour or lb/mmBtu)	Additional information
Blast Furnace	0.03 lb/mmBtu	OH NO_X RACT rules limit NO_X emissions from blast furnaces to 0.06 lb/mmBtu without requiring specific control technology. Control NO_X at stoves (typically 3 or 4 per blast furnace), assuming 40–50% reduction) by burner replacement plus SCR.
Basic Oxygen Furnace	0.07 lb/ton	Potential 25–50% reduction by SCR/SNCR from 0.14 lb/ton based on emissions testing.
Electric Arc Furnace	0.15 lb/ton steel	Example permit limits at around 0.2 lb/ton. Assumes 25% reduction by SCR to achieve 0.15 lb/ton steel.
Ladle/tundish Preheaters	0.06 lb/mmBtu	Nucor Kankakee BACT permit limit issued January 2021 is 0.1 lb/mmBtu, 2021. Assume 40% reduction by SCR.
Reheat furnace	0.05 lb/mmBtu	Sterling Steel permit, issued 2019: Low-NO_X natural gas fired burners designed to emit no more than 0.073 lb NO_X/mmBtu, Ohio RACT limit is 0.09 lb/mmBtu. Assume 40% reduction by SCR.
Annealing Furnace	0.06 lb/mmBtu	Big River Steel (AR) 2018 limit and Benteler Steel (LA) 2019 limit (0.11 lb/mmBtu), 85 mmBtu/hr and 13 mmBtu/hr, respectively. Lowest was 0.0915 lb/mmBtu, Nucor AR. Assume 40% reduction by SCR.
Vacuum Degasser	0.03 lb/mmBtu	0.05 lb/mmBtu Nucor Darlington (SC) and Nucor Tuscaloosa (AL). Assume 40% reduction by SCR.
Ladle Metallurgy Furnace	0.1 lb/ton	Assume 40% reduction by SCR.
Taconite Production Kilns	Work practice standard to install and operate low NO_X burners.	Consistent with requirements in Minnesota Taconite FIP *See 81 FR 21671.*
Coke Ovens (charging)	0.15 lb/ton of coal charged	Assume 50% reduction staged combustion and/or limited use SCR/SNCR during charging operations from AP–42 0.3 lb/ton emission factor.
Coke Ovens (pushing)	0.015 lb/ton of coal pushed	SunCoke Middletown limit is 0.02 lb/ton of coal. Assume 25% reduction by SCR.
Boilers—Coal	0.20 lb/mmBtu	See explanation in Section VII.C.5.
Boilers—Residual oil	0.20 lb/mmBtu	See explanation in Section VII.C.5.
Boilers—Distillate oil	0.12 lb/mmBtu	See explanation in Section VII.C.5.

TABLE VII.C–3—SUMMARY OF PROPOSED NO_X EMISSIONS LIMITS FOR IRON AND STEEL AND FERROALLOY EMISSIONS UNITS—Continued

Emissions unit	Proposed NO_X emissions standard or requirement (lbs/hour or lb/mmBtu)	Additional information
Boilers—Natural gas	0.08 lb/mmBtu	See explanation in Section VII.C.5.

Due to the many types of units within Iron and Steel Mills and Ferroalloy Manufacturing facilities that are not currently subject to NO_X limitations of the stringency necessary to eliminate significant contribution, most of the emissions limits in this proposed rule are based on examples of permitted emissions and estimated reduction potential from the identified control technology. Based on the selection of SCR, SNCR, and burner replacement in the non-EGU screening assessment, the EPA assumed reductions of 20 to 50 percent from current permitted limits and emissions tests depending on the type of unit and controls being implemented.

In addition, for Taconite Production Kilns, the EPA does not currently have the data to determine appropriate emissions limits that these units could achieve by installing low NO_X burners. Therefore, the EPA is proposing to require the installation of low NO_X burners for Taconite Production Kilns and work practice standards for operating these control technologies to achieve emissions reductions. The EPA is also proposing to require these sources to perform performance tests and establish a unit-specific emissions limit at that time. These work practice standards are consistent with EPA's Taconite FIP for Minnesota. *See* 81 FR 21671 (April 12, 2016). Due to the ongoing nature of this FIP, the EPA is proposing to require installation of specific control technologies and a period of evaluation before setting a numerical emissions limit.

Compliance Assurance Requirements

The EPA is proposing to require each owner or operator of an affected facility that is subject to the NO_X emissions limit for Iron and Steel Mills and Ferroalloy Manufacturing emissions units contained in this section to install, calibrate, maintain, and operate a CEMS for the measurement of NO_X emissions discharged into the atmosphere from the affected facility. The EPA is proposing that each emissions unit will be required to conduct an initial performance test and to operate CEMS to assure compliance. In conducting the performance tests to demonstrate compliance, sources must use test methods and procedures in 40 CFR 60 appendix A, Method 7E, or other EPA-approved (federally enforceable) test methods and procedures. The EPA is also soliciting comments on alternative monitoring systems or methods that are equivalent to CEMS to demonstrate compliance with the emissions limits.

4. Glass and Glass Product Manufacturing

Applicability

The EPA is proposing to establish regulatory requirements for the Glass and Glass Product Manufacturing source category that apply to emissions units that directly emit or have the potential to emit 100 tpy or more of NO_X. The EPA is setting emissions limits based on type of unit to ensure that the necessary emissions reductions occur. The EPA is seeking comment on whether it should set an applicability threshold based on a unit's production capacity rather than an emissions threshold.

Emissions Limitations and Rationale

In developing the emissions limits for the Glass and Glass Product Manufacturing industry, the EPA reviewed RACT NO_X rules, air permits, Alternative Control Techniques (ACT), and consent decrees. These rules and source-specific requirements most commonly express the emissions limits for this industry in terms of mass of pollutant emitted (pounds) per weight of glass removed from the furnace (tons), *i.e.,* pounds of NO_X emitted per ton of glass produced. A regulated entity routinely monitors and keeps track of its glass outputs as it pertains to a furnace's design capacity and the plant's production. Therefore, the EPA believes that this form of NO_X emissions limit is effective, practicable, and convenient to record and report to an air agency.

In determining the averaging time for the limits, the EPA initially reviewed the NSPS for glass manufacturing plants codified at 40 CFR part 60 subpart CC. This NSPS applied to any glass melting furnace in an affected facility that commenced construction or modification after June 15, 1979, and produced more than 5 tons of glass per day. It was noted that the NSPS only provides standards for particulate matter and does not provide standards or averaging times for NO_X. In order to determine the averaging time for the NO_X emissions limits, the EPA reviewed various RACT NO_X rules from states located within the OTR, several of which have chosen to implement OTC model rules and recommendations.

Most of the states within the OTR implement RACT regulations for the glass manufacturing industry that do not specify presumptive NO_X limits.[316] With respect to those RACT rules in the OTR states that contain presumptive RACT NO_X limits for glass manufacturing furnaces, EPA found variations in averaging times, ranging from a 30-day rolling average to a more stringent daily average.[317] The EPA also reviewed RACT NO_X regulations for the glass manufacturing industry outside the OTR and observed that 30-day rolling averages and daily averages varied throughout the states.[318] The EPA is proposing to require owners or operators of glass manufacturing furnaces to comply with the applicable presumptive NO_X emissions limits on a 30-day rolling average time frame. This averaging time frame is consistent with other statewide RACT NO_X regulations for this particular industry. Furthermore, a state's air agency may choose to require an averaging period shorter than a 30-operating day rolling

[316] RACT NO_X rules of the following OTR states CT, DC, DE, MD, ME, NH, NY, RI, VA, and VT do not provide presumptive NO_X limits for glass manufacturing sources. These RACT regulations require owners or operators to submit RACT case-by-case analysis.

[317] Pennsylvania's presumptive RACT NO_X emissions limits are based on 30-day rolling average. New Jersey's and Massachusetts' rules contain more stringent daily averages. Maryland's RACT rule, section 26.11.09.08.I, requires owner or operators to optimize combustion by performing daily oxygen tests and maintain excess oxygen at 4.5% or less. See *http://www.dsd.state.md.us/comar/comarhtml/26/26.11.09.08.htm.*

[318] For example, presumptive RACT NO_X emissions limits in California are based on both 30-day rolling and daily averages (*see https://www.valleyair.org/rules/currntrules/R4354%20051911.pdf*). Wisconsin's NO_X emissions limits are based on a 30-day rolling average (*see https://casetext.com/regulation/wisconsin-administrative-code/agency-department-of-natural-resources/environmental-protection-air-pollution-control/chapter-nr-428-control-of-nitrogen-compound-emissions/subchapter-iv-NOX-reasonably-available-control-technology-requirements/section-nr-42822-emission-limitation-requirements*).

average in air permits or RACT regulations for these plants. The EPA finds that a 30-operating day rolling average period provides a reasonable balance between short term (hourly or daily) and long term (annual) averaging periods, while being flexible and responsive to fluctuations in operation and production.

Based on the available information for this industry, applicable state and local air agency rules, and active air permits or enforceable orders issued to affected glass manufacturing plants, EPA is proposing the following emissions limits for glass manufacturing furnaces:

TABLE VII.C–4—SUMMARY OF PROPOSED NO_X EMISSIONS LIMITS FOR FURNACE UNIT TYPES IN GLASS AND GLASS PRODUCT MANUFACTURING

Furnace type	Proposed NO_X emissions limit (lb/ton of glass produced)	Additional information
Container Glass Manufacturing Furnace.	4.0	Limits reviewed ranged between 1–4; one state rule allowed as high as 5; with addition of post combustion NO_X controls, the upper range could be reduced significantly; consistent with 25 Pennsylvania Code 129.304(a)(1) and New Jersey Administrative Code 7:27 Subchapter 19.1.
Pressed/Blown Glass Manufacturing Furnace or Fiberglass Manufacturing Furnace.	4.0	Limits reviewed ranged between 1.36–4; one state rule allowed as high as 7; with addition of post combustion control the limit could be reduced significantly; limit of 4.0 is consistent with RACT regulations for states located within OTR.
Flat Glass Manufacturing Furnace.	9.2	Limits reviewed ranged between 5–9.2; with the addition of post combustion controls the limit could be reduced significantly; consistent with San Joaquin Valley Air Pollution Control District Rule 4354 5.1.1 and New Jersey Administrative Code 7:27 Subchapter 19.1.

The EPA is soliciting comment on whether it is feasible or appropriate to phase out and retire existing glass manufacturing furnaces in the affected states and replace them with more energy efficient and less emitting units like all-electric melter installations. The EPA is also requesting comment on the time needed to complete such a task. All-electric melters are glass melting furnaces in which all the heat required for melting is provided by electric current from electrodes submerged in the molten glass.[319] All-electric melter furnaces could provide an energy efficient and NO_X emission-free alternative to current methods of melting and producing glass.

According to the EPA's ''Alternative Control Techniques Document—NO_X Emissions from Glass Manufacturing,'' [320] glass manufacturing furnaces may utilize combustion modifications equivalent to low-NO_X burners and oxy-firing. The EPA is soliciting comment on whether it is feasible or appropriate to require sources with existing glass manufacturing furnaces in affected states that currently utilize these combustion modifications to add and operate a post-combustion control device like SNCR and SCR to further improve their NO_X removal efficiency. The EPA is also requesting comments on the time needed to install such controls.

Compliance Assurance Requirements

The EPA is proposing to require each owner or operator of an affected facility that is subject to the NO_X emissions standards for glass manufacturing furnaces contained in this section to install, calibrate, maintain, and operate a CEMS for the measurement of NO_X emissions discharged into the atmosphere from the affected facility. The EPA is also soliciting comments on alternative monitoring systems or methods that are equivalent to CEMS to demonstrate compliance with the emissions limits. In conducting the performance tests to demonstrate compliance, sources must use test methods and procedures in 40 CFR part 60 appendix A, method 7E, or other EPA-approved (federally enforceable) methods and procedures. Owners or operators must calculate and record the 30-operating day rolling emissions rate of NO_X as the total of all hourly emissions data for a glass manufacturing furnace in the preceding 30 days, divided by the total tons of glass produced in that furnace during the same 30-operating day period. Owners or operators of glass manufacturing furnaces installed with continuous emissions monitoring may demonstrate compliance with the emissions limit as follows: (1) Determine the average pounds of NO_X emitted per day, (2) determine the tons of glass removed per day during the same day, (3) divide the average pounds of NO_X emitted per day by the tons of glass removed per day as determined in step (2), and (4) compare the quotient to the emissions limits prescribed in the Section VII of this proposed rule. If the pollutant mass emissions rate is in lb/hr, the following equation [321] shall be used to convert the emissions rate to lb pollutant/ton of glass pulled:

$$lb\ emitted / ton\ of\ glass\ pulled = \frac{\frac{lb}{hr} emitted}{Pull\ rate\ in \frac{tons}{hr}}$$

[319] *See* definitions in 40 CFR part 60 subpart CC.

[320] ''Alternative Control Techniques Document—NO_X Emissions from Glass Manufacturing,'' EPA–453/R–94–037, June 1994.

[321] This equation is provided in the San Joaquin Valley Unified Air Pollution Control District's Rule 4354, section 8.1.

5. Boilers From Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mills

Applicability

The EPA is proposing to establish regulatory requirements for the Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mills industries that apply to boilers within these facilities that have a design capacity of 100 mmBtu/hr or greater. These requirements are consistent with EPA's findings at Step 3 with respect to Tier 2 non-EGU industries. As noted below, we do not believe boilers meeting this size classification exist within the other Tier 2, or Tier 1 industries, but if they do, the EPA proposes that they would also be subject to the requirements of this part. Based on our review of the potential emissions from industrial boilers of various fuel types, we find that use of a boiler design capacity of 100 mmBtu/hr reasonably approximates the selection of 100 tpy used within the Non-EGU Screening Assessment memorandum. Therefore, boilers subject to the requirements of this section of the proposed rule are those found within any of the 23 covered states with non-EGU emissions reduction obligations that are within a Tier 1 or Tier 2 industry and have a design capacity of 100 mmBTU/hr or greater. The EPA is seeking comment on whether EPA should alternatively set an applicability threshold based on potential to emit.

Emissions Limitations and Rationale

This section of the proposed rule applies to certain boilers located at any facility identified as a Tier 2 industry within the non-EGU screening assessment. As described within the Non-EGU Screening Assessment memorandum, the EPA reviewed the projected 2026 emissions data to identify large boilers within the Tier 2 industries, defined as boilers projected to emit more than 100 tons per year in 2026. Boilers meeting this threshold were found in three of the five Tier 2 industries, as identified in Table VII.C.5–1.

TABLE VII.C.5–1—TIER 2 INDUSTRIES WITH LARGE BOILERS AND ASSOCIATED NAICS CODES

Industry	NAICS code
Basic Chemical Manufacturing	3251xx
Petroleum and Coal Products Manufacturing	3241xx
Pulp, Paper, and Paperboard Mills	3221xx

The EPA did not find large boilers within the Lime and Gypsum Product Manufacturing (NAICS code 3274xx) or the Metal Ore Mining industries (NAICS code 2122xx). As such the EPA is not expressly proposing to include boilers in those industries. However, if as a result of receiving additional information during the comment period the EPA identifies large boilers within these two industries that meet the applicability criteria described below, those boilers could be subject to the requirements of the final rule.

As described within the Non-EGU Sectors TSD, the RACT rules we reviewed containing NO_X limits for industrial boilers relied primarily on design capacity in mmBtu/hr as the metric for selecting design criteria. The EPA is proposing to use that same metric to establish control requirements for boilers with a design capacity of 100 mmBtu/hr or greater. As noted within the Non-EGU Sectors TSD, boilers rated at 100 mmBtu/hr or greater can emit large amounts of NO_X, particularly if they do not operate NO_X control equipment.

The EPA reviewed NO_X emissions limits for industrial boilers with design capacities of 100 mmBtu/hr or greater that have been adopted by states and incorporated into their SIPs. The Non-EGU Sectors TSD contains a detailed discussion of that evaluation. Based on our review, we propose to establish the following NO_X emissions limits for coal, oil, and gas fired industrial boilers located at a Tier 2 industry:

TABLE VII.C.5–2—PROPOSED NO_X EMISSIONS LIMITS FOR INDUSTRIAL BOILERS >100 MMBTU/HR

Unit type	Emissions limit (lbs NO_X/mmBtu)	Additional information
Coal	0.20	Limits reviewed ranged from 0.08 to 1.0. Proposed limit will likely require a combination of combustion controls or post-combustion controls.
Residual oil	0.20	Limits reviewed ranged from 0.15 to 0.50. Proposed limit will likely require combustion controls.
Distillate oil	0.12	Limits reviewed ranged from 0.10 to 0.43. Proposed limit will likely require combustion controls.
Natural gas	0.08	Limits reviewed ranged from 0.06 to 0.25. Proposed limit will likely require a combination of combustion controls or post-combustion controls.

Additional information on the EPA's derivation of these proposed emissions rates for boilers is provided below and in the Non-EGU Sectors TSD.

The EPA notes that some coal, oil, and gas-fired industrial boilers may have already installed combustion or post-combustion control equipment, such as SCR or SNCR, sufficient to meet the emission limits established in this FIP. Some of the boilers covered by this FIP might have install controls to meet the emission limits contained within EPA's NSPS located at 40 CFR 60 Subpart Db, which requires that some fossil fuel-fired units that commenced construction, modification, or reconstruction after June 19, 1984, meet various NO_x emission limits based on factors such as unit type or heat rate. Additionally, industrial boilers located in ozone nonattainment areas or within the ozone transport region may have installed controls to meet emission limits adopted by states to meet NO_x RACT requirements.

a. Coal-Fired Industrial Boilers

Coal-fired industrial boilers subject to the proposed requirements of this section would have to meet a NO_X emissions limit of 0.2 lbs/mmBtu on a 30-day rolling average basis.

Various forms of combustion and post-combustion NO_X control technology exist that should enable most facilities to be retrofit with equipment that will enable them to meet these emissions limits. Additionally, as noted in the Non-EGU Sectors TSD, many states containing ozone nonattainment areas or located within the OTR have already adopted emissions limits similar to or more stringent than the limits the EPA proposes here. Furthermore, some coal-fired industrial boilers may have installed combustion or post-combustion control equipment to meet the emissions limits contained within EPA's NSPS located at 40 CFR part 60 subpart Db, which requires that coal-fired industrial boilers meet a NO_X emissions limit of between 0.5 and 0.8

lbs/mmBtu depending on unit type.[322] Enhancements to or retrofit of additional NO_X control technology should enable most sources to meet the proposed NO_X limit.

There are two main types of NO_X control technology that we believe can be retrofit to most existing industrial boilers, or incorporated into the design of new boilers, to meet our proposed emissions limits. These two control types are combustion controls and post-combustion controls, and in some instances both types are used together. As noted in the EPA's ''Alternative Control Techniques Document—NO_X Emissions from Industrial/Commercial/Institutional (ICI) Boilers'' (hereafter ''ICI Boiler ACT''),[323] the type of NO_X control available for use on a particular unit depends primarily on the type of boiler, fuel type, and fuel-firing configuration. For example, Table 2–3 of the ICI Boiler ACT indicates which types of combustion and post-combustion NO_X controls are suitable to various types of coal-fired ICI boilers. We note that one type of combustion control, staged combustion air, and one type of post-combustion control, SNCR, are indicated as being compatible with all coal-fired unit types. Additional resources are available that document the availability of NO_X control equipment for industrial boilers.[324]

b. Oil-Fired Industrial Boilers

Most oil-fired boilers are fueled by either residual (heavy) oil or distillate (light) oil. The proposed NO_X emissions limit for residual oil-fired boilers subject to the requirements of this section is 0.2 lbs/mmBtu, and the proposed emissions limit for distillate oil-fired boilers is 0.12 lbs/mmBtu. The proposed averaging time for these emissions limits is a 30-day rolling average. As with coal-fired industrial boilers, a number of combustion and post-combustion NO_X control technologies exist that should enable most facilities to meet these emissions limits, and the Non-EGU Sectors TSD identifies numerous states that have already adopted emissions limits similar to the limits EPA proposes here. Table 2–3 of the ICI Boiler ACT indicates that two types of NO_X combustion control, low-NO_X burners and flue gas recirculation, are commonly found on oil-fueled industrial boilers, and that SNCR, a post-combustion control technology, is suitable to most oil-fueled industrial boilers other than those of the packaged firetube design. Some oil-fired industrial boilers may have already installed combustion or post-combustion control equipment to meet the emissions limits contained within EPA's NSPS at 40 CFR part 60 subpart Db, which requires that distillate oil-fired units meet a NO_X emissions limit of between 0.1 to 0.2 lbs/mmBtu depending on heat release rate, and that residual oil-fired units meet a NO_X emissions limit of between 0.3 to 0.4 lbs/mmBtu also depending on heat release rate.[325] The additional resources noted in the paragraph above discussing coal-fired industrial boilers also contain useful information regarding effective NO_X control equipment for residual and distillate fueled industrial boilers.

c. Gas-Fired Industrial Boilers

The proposed NO_X emissions limit for gas-fired boilers subject to the requirements of this section is 0.08 lbs/mmBtu. The proposed averaging time for these emissions limits is a 30-day rolling average.

As with fossil-fuel-fired boilers, numerous combustion and post-combustion NO_X control technologies exist that should enable most facilities to meet these emissions limits, and many states have already adopted emissions limits similar to the limits the EPA proposes here. Table 2–3 of the ICI Boiler ACT indicates the same control technologies that are suitable for application to oil-fired boilers are also likely to be effective at controlling NO_X emissions from gas-fired industrial boilers. Some gas-fired industrial boilers may have already installed combustion or post-combustion control equipment to meet the emissions limits contained within EPA's NSPS at 40 CFR 60 Subpart Db, which requires that gas-fired units meet a NO_X emissions limit of between 0.1 to 0.2 lbs/MMBtu depending on heat release rate. The additional resources noted in the discussion of coal-fired industrial boilers also contain useful information regarding effective NO_X control equipment for gas-fired industrial boilers.

The EPA anticipates that the majority of boilers covered by this section of the FIP will combust one of the fuels for which we have proposed emissions limits. However, we request comment on whether emissions limits for other types of fuels should be included in a final FIP, and if so, the types of fuels and the emissions limits that boilers powered by these fuels should be required to meet. Additionally, the EPA seeks comment on whether the EPA should establish less stringent emissions rates for boilers with low utilization rates, and if so, the appropriate emissions rate(s) and corresponding boiler utilization rate(s). The EPA also seeks comment on whether a different averaging time other than the 30-day averaging time proposed for boilers would be more appropriate and requests information supporting any suggested alternative.

Compliance Assurance Requirements

Given the similarities in the types of units covered, the EPA proposes that boilers subject to the requirements of this section demonstrate compliance in a manner similar to the emissions monitoring requirements found in section 60.45 of the NSPS for industrial, commercial, and institutional (ICI) boilers at 40 CFR part 60 subpart D. Those requirements include, among other provisions, the performance of an initial compliance test, installation of a CEMS unless the initial performance test indicates the unit's emissions rate is 70 percent or less of the required emissions rate, and an annual stack test for units not required to install a CEMS.

D. Submitting a SIP

A state may submit a SIP at any time to address CAA requirements that are covered by a FIP, and if the EPA approves the SIP it would replace the FIP, in whole or in part, as appropriate.[326] The EPA has established certain specialized provisions for replacing FIPs with SIPs within all the CSAPR trading programs, including the use of so-called ''abbreviated SIPs'' and ''full SIPs,'' *see* 40 CFR 52.38(a)(4) and (5) and (b)(4), (5), (8), (9), (11), and (12); 40 CFR 52.39(e), (f), (h), and (i). For a state to remove all FIP provisions through an approved SIP revision, a state would need to address all of the required reductions addressed by the FIP for that state, *i.e.,* reductions achieved through both EGU control and non-EGU control, as applicable to that state. Additionally, tribes in Indian country within the geographic scope of this proposed rule may elect to work with EPA under the Tribal Authority Rule to replace the FIP for areas of Indian country, in whole or in part, with a tribal implementation plan or

[325] 40 CFR 60.44b.

[326] CAA sections 110(c)(1)(B), 110(k)(3).

reasonably severable portions of a tribal implementation plan.

Under the proposed new FIPs for the 25 states whose EGUs would be required to participate in the CSAPR NO_X Ozone Season Group 3 Trading Program with its proposed modifications, ''abbreviated'' and ''full'' SIP options continue to be available. An ''abbreviated SIP'' allows a state to submit a SIP revision that would establish state-determined allowance allocation provisions replacing the default FIP allocation provisions but leaves the remaining FIP provisions in place. A ''full SIP'' allows a state to adopt a trading program meeting certain requirements that would allow sources in the state to continue to use the EPA-administered trading program through an approved SIP revision, rather than a FIP. In addition, as under past CSAPR rulemakings, the EPA proposes to provide states with an opportunity to adopt state-determined allowance allocations for existing units for the second control period under this rule—in this case, the 2024 control period—through streamlined SIP revisions. *See* 76 FR 48326–48332 for additional discussion of full and abbreviated SIP options; *see also* 40 CFR 52.38(b).

1. SIP Option To Modify Allocations for 2024 Under EGU Trading Program

As with the start of past CSAPR rulemakings, the EPA proposes to allow a state to use a similar process to submit a SIP revision establishing allowance allocations for existing EGU units in the state for the second control period of the new requirements, *i.e.,* in 2024, to replace the EPA-determined default allocations. This proposed process would use updated deadlines, *i.e.,* a state must submit a letter to EPA within 60 days of publication of the final rule indicating its intent to submit a complete SIP revision by September 1, 2023. The SIP would provide in an EPA-prescribed format a list of existing units within the state and their allocations for the 2024 control period. If a state does not submit a letter of intent to submit a SIP revision, the EPA-determined default allocations will be recorded by 90 days of publication of the final rule. If a state submits a timely letter of intent but fails to submit a SIP revision, the EPA-determined default allocations will be recorded by September 15, 2023. If a state submits a timely letter of intent followed by a timely SIP revision that is approved, the approved SIP allocations will be recorded by March 1, 2024.

The EPA requests comment on the proposed option to modify allowance allocations under the Group 3 trading program for EGUs for the 2024 control period through a SIP revision.

2. SIP Option To Modify Allocations for 2025 and Beyond Under EGU Trading Program

For the 2025 control period and later, the EPA proposes that states in the CSAPR NO_X Ozone Season Group 3 Trading Program can modify the EPA-determined default allocations with an approved SIP revision. For the 2025 control period and later, SIPs can be full or abbreviated SIPs. States will also have the option to expand applicability to include EGUs between 15 MWe and 25 MWe or, in the case of states subject to the NO_X SIP Call, as discussed in Section VII.F.1 of this proposed rule, large non-EGU boilers and combustion turbines. Inclusion of the large non-EGUs would serve as a mechanism to address the state's outstanding regulatory obligations under the NO_X SIP Call with respect to those sources, and the state would be allowed to allocate a defined quantity of additional Group 3 allowances because of the expanded set of sources. *See* above and 76 FR 48326–48332 for additional discussion of full and abbreviated SIP options; *see also* 40 CFR 52.38(b).

For states that want to modify the EPA-determined default allocations or expand applicability of the EGU trading program, the EPA proposes that a state could submit a SIP revision that makes changes only to one or both of those type of provisions while relying on the FIP for the remaining provisions of the EGU trading program. This abbreviated SIP option allows states to tailor the FIP to their individual choices while maintaining the FIP-based structure of the trading program. In order to ensure the availability of allowance allocations for units in any Indian country within a state not covered by the state's CAA implementation planning authority, if the state chose to replace EPA's default allocations with state-determined allocations, the EPA would continue to administer any portion of each state emissions budget reserved as a new unit set-aside or an Indian country existing unit set-aside.

The proposed SIP submittal deadline for this type of revision is December 1, 2023, if the state intends for the SIP revision to be effective beginning with the 2025 control period. For states that submit this type of SIP revision, the EPA proposes that the deadline to submit state-determined allocations beginning with the 2025 control period under an approved SIP would be June 1, 2024, and the deadline for the EPA to record those allocations would be July 1, 2024. Similarly, under the proposed new deadlines a state could submit a SIP revision beginning with the 2026 control period and beyond by December 1, 2024, with state allocations for the 2026 control period due June 1, 2025, and the EPA recordation of the allocations by July 1, 2025.

The EPA requests comment on the proposed option to replace certain allowance allocation or applicability provisions under the Group 3 trading program for EGUs for control periods in 2025 and later years through a SIP revision.

3. SIP Option To Replace the Federal EGU Trading Program With an Integrated State EGU Trading Program

For the 2025 control period and later, the EPA proposes that states in the CSAPR NO_X Ozone Season Group 3 Trading Program can choose to replace the Federal EGU trading program with an integrated State EGU trading program through an approved SIP revision. Under this option, a state would submit a SIP revision that makes changes only to modify the EPA-determined default allocations or expand applicability of the EGU trading program and adopt identical provisions for the remaining portions of the EGU trading program. This SIP option allows states to replace these FIP provisions with state-based SIP provisions while continuing participation in the larger regional trading program. As with the abbreviated SIP option discussed above, in order to ensure the availability of allowance allocations for units in any Indian country within a state not covered by the state's CAA implementation planning authority, if the state chose to replace EPA's default allocations with state-determined allocations, EPA would continue to administer any portion of each state emissions budget reserved as a new unit set-aside or an Indian country existing unit set-aside.

Proposed deadlines for this type of SIP revision are the same as the deadlines for abbreviated SIP revisions. For the SIP-based program to start with the 2025 control period, the SIP deadline would be December 1, 2023, the deadline to submit state-determined allocations for the 2025 control period under an approved SIP would be June 1, 2024, and the deadline for the EPA to record those allocations would be July 1, 2024, and so on.

The EPA requests comment on the proposed option to replace the federal trading program for EGUs with an integrated state trading program for EGUs for control periods in 2025 and later years through a SIP revision.

4. SIP Revisions That Do Not Use the New Trading Program

States can submit SIP revisions to replace the FIP that achieve the necessary EGU emissions reductions but do not use the CSAPR NO_X Ozone Season Group 3 Trading Program. For a transport SIP revision that does not use the CSAPR NO_X Ozone Season Group 3 Trading Program, the EPA would evaluate the transport SIP based on the particular control strategies selected and whether the strategies as a whole provide adequate and enforceable provisions ensuring that the necessary emissions reductions (*i.e.,* reductions equal to or greater than what the Group 3 trading program will achieve) will be achieved. In order to address the applicable CAA requirements, the SIP revision should include the following general elements: (1) A comprehensive baseline 2023 statewide NO_X emissions inventory (which includes existing control requirements), which should be consistent with the 2023 emissions inventory that the EPA used to calculate the required state budget in this final proposed rule (unless the state can explain the discrepancy); (2) a list and description of control measures to satisfy the state emissions reduction obligation and a demonstration showing when each measure would be implemented to meet the 2023 and successive control periods; (3) fully-adopted state rules providing for such NO_X controls during the ozone season; (4) for EGUs greater than 25 MWe, monitoring and reporting under 40 CFR part 75, and for other units, monitoring and reporting procedures sufficient to demonstrate that sources are complying with the SIP (*see* 40 CFR part 51 subpart K (''source surveillance'' requirements)); and (5) a projected inventory demonstrating that state measures along with federal measures will achieve the necessary emissions reductions in time to meet the 2023 and successive compliance deadlines (*e.g.,* enforceable reductions commensurate with installation of SCR on coal-fired EGUs by the 2026 ozone season). The SIPs must meet procedural requirements under the Act, such as the requirements for public hearing, be adopted by the appropriate state board or authority, and establish by a practically enforceable regulation or permit(s) a schedule and date for each affected source or source category to achieve compliance. Once the state has made a SIP submission, the EPA will evaluate the submission(s) for completeness before acting on the SIP. EPA's criteria for determining completeness of a SIP submission are codified at 40 CFR part 51 appendix V.

For further information on replacing a FIP with a SIP, *see* the discussion in the final CSAPR rulemaking (76 FR 48326).

5. SIP Revision Requirements for Non-EGU Emissions Limits

EPA's promulgation of a non-EGU transport FIP would in no way affect the ability of states to submit, for review and approval, a SIP that replaces the requirements of the FIP with state requirements. In order to replace the non-EGU portion of the FIP in a state, the state's SIP must provide adequate provisions to prohibit an equivalent or greater amount of NO_X emissions that contribute significantly to nonattainment or interfere with maintenance of the 2015 ozone NAAQS in any other state. The non-EGU requirements of the FIP would remain in place in each covered state until a state's SIP has been approved by the EPA to replace the FIP.

After promulgation of the final FIP, the EPA anticipates that the most straightforward method for a state to submit a SIP revision to replace the non-EGU portion of the FIP for the state would be to provide a SIP that includes emissions limits at an equivalent or greater level of stringency than is specified for non-EGU sources meeting the applicability criteria and associated compliance assurance provisions for each of the unit types identified in Section VII.C of this proposed rule.

The EPA seeks comment on other potential methods by which states could develop a SIP to obtain emissions reductions from non-EGU sources that would replace the state's non-EGU portion of the FIP. The EPA recognizes that states may select emissions reductions strategies that differ from the emissions limitations included in the proposed non-EGU FIP. But the state must still demonstrate that the replacement SIP provides an equivalent or greater amount of emissions reductions as the proposed FIP. The EPA anticipates that such emissions reductions strategies would have to achieve reductions beyond those emissions reductions already projected to occur in EPA's emissions projections and air quality modeling conducted at Steps 1 and 2. Such reductions must also be achieved on the same timeframe as the reductions that would be required in a final FIP. A demonstration of equivalency using other control strategies is complicated by the fact that the proposed emissions limits for non-EGU sources are generally rate-based and expressed in a variety of forms; this will make comparative analysis to determine equivalency challenging.

In all cases, a SIP submitted by a state to replace the non-EGU FIPs would need to rely on permanent and practically enforceable controls measures that are included in the SIP and, once approved by the EPA, rendered federally enforceable. So-called ''demonstration-only'' or ''non-regulatory'' SIPs would be insufficient. Further, the EPA anticipates that states would bear the burden of establishing that the state's alternative approach achieves at least an equivalent level of emissions reduction as the FIP, and (unless merely adopting directly the control requirements of the FIP) the state would need to provide a Step 3 multifactor analysis that the state's SIP eliminates significant contribution.

E. Title V Permitting

This proposed rule, like CSAPR, the CSAPR Update, and the Revised CSAPR Update does not establish any permitting requirements independent of those under Title V of the CAA and the regulations implementing Title V, 40 CFR parts 70 and 71.[327] All major stationary sources of air pollution and certain other sources are required to apply for title V operating permits that include emissions limitations and other conditions as necessary to ensure compliance with the applicable requirements of the CAA, including the requirements of the applicable SIP. CAA sections 502(a) and 504(a), 42 U.S.C. 7661a(a) and 7661c(a). The ''applicable requirements'' that must be addressed in title V permits are defined in the title V regulations (40 CFR 70.2 and 71.2 (definition of ''applicable requirement'')).

The EPA anticipates that, given the nature of the units subject to this proposed rule, most if not all of the sources at which the units are located are already subject to title V permitting requirements. For sources subject to title V, the interstate transport requirements for the 2015 ozone NAAQS that are applicable to them under the new or amended FIPs would be ''applicable requirements'' under title V and therefore must be addressed in the title V permits. For example, requirements concerning designated representatives, monitoring, reporting, and recordkeeping, the requirement to hold allowances covering emissions, the compliance assurance provisions, and liability are ''applicable requirements'' that must be addressed in the permits.

Title V of the CAA establishes the basic requirements for state title V

[327] Part 70 addresses requirements for state title V programs, and Part 71 governs the federal title V program.

permitting programs, including, among other things, provisions governing permit applications, permit content, and permit revisions that address applicable requirements under final FIPs in a manner that provides the flexibility necessary to implement market-based programs such as the trading programs established in CSAPR, the CSAPR Update, the Revised CSAPR Update and this proposed rule. 42 U.S.C. 7661a(b); 40 CFR 70.6(a)(8) & (10); 40 CFR 71.6(a)(8) & (10).

In CSAPR, the CSAPR Update and the Revised CSAPR Update, the EPA established standard requirements governing how sources covered by that rule would comply with title V and its regulations.[328] 40 CFR 97.506(d), 97.806(d) and 97.1006(d). For any new or existing sources subject to this proposed rule, identical title V compliance provisions would apply, just as they would have in the CSAPR NO_X Ozone Season Group 3 Trading Program. For example, the title V regulations provide that a permit issued under title V must include ''[a] provision stating that no permit revision shall be required under any approved . . . emissions trading and other similar programs or processes for changes that are provided for in the permit.'' 40 CFR 70.6(a)(8) and 71.6(a)(8). Consistent with these provisions in the title V regulations, in CSAPR, the CSAPR Update and the Revised CSAPR Update, the EPA included a provision stating that no permit revision is necessary for the allocation, holding, deduction, or transfer of allowances. 40 CFR 97.506(d)(1), 97.806(d)(1) and 97.1006(d)(1). This provision is also included in each title V permit for an affected source. This proposed rule maintains the approach taken under CSAPR, the CSAPR Update and the Revised CSAPR Update that allows allowances to be traded (or allocated, held, or deducted) without a revision to the title V permit of any of the sources involved.

Similarly, this proposed rule would also continue to support the means by which a source in the proposed trading program can use the title V minor modification procedure to change its approach for monitoring and reporting emissions, in certain circumstances. Specifically, sources may use the minor modification procedure so long as the new monitoring and reporting approach is one of the prior-approved approaches under CSAPR, the CSAPR Update and the Revised CSAPR Update (*i.e.,* approaches using a continuous emissions monitoring system under subparts B and H of part 75, an excepted monitoring system under appendices D and E to part 75, a low mass emissions excepted monitoring methodology under 40 CFR 75.19, or an alternative monitoring system under subpart E of part 75), and the permit already includes a description of the new monitoring and reporting approach to be used. *See* 40 CFR 97.506(d)(2), 97.806(d)(2) and 97.1006(d)(2); 40 CFR 70.7(e)(2)(i)(B) and 40 CFR 71.7(e)(1)(i)(B). As described in EPA's 2015 Title V Guidance, sources may comply with this requirement by including a table of all of the approved monitoring and reporting approaches under CSAPR, the CSAPR Update and the Revised CSAPR Update trading programs in which the source is required to participate, and the applicable requirements governing each of those approaches.[329] Inclusion of such a table in a source's title V permit therefore allows a covered unit that seeks to change or add to its chosen monitoring and recordkeeping approach to easily comply with the regulations governing the use of the title V minor modification procedure.

Under CSAPR, the CSAPR Update and the Revised CSAPR Update, in order to employ a monitoring or reporting approach different from the prior-approved approaches discussed previously, unit owners and operators must submit monitoring system certification applications to the EPA establishing the monitoring and reporting approach actually to be used by the unit, or, if the owners and operators choose to employ an alternative monitoring system, to submit petitions for that alternative to the EPA. These applications and petitions are subject to the EPA review and approval to ensure consistency in monitoring and reporting among all trading program participants. EPA's responses to any petitions for alternative monitoring systems or for alternatives to specific monitoring or reporting requirements are posted on EPA's website.[330] The EPA maintains the same approach in this proposed rule.

Consistent with EPA's approach under CSAPR, the CSAPR Update and the Revised CSAPR Update, the applicable requirements resulting from the new and amended FIPs generally will have to be incorporated into affected sources' existing title V permits either pursuant to the provisions for reopening for cause (40 CFR 70.7(f) and 71.7(f)) or the standard permit renewal provisions (40 CFR 70.7(c) and 71.7(c)).[331] For sources newly subject to title V that are affected sources under the FIPs, the initial title V permit issued pursuant to 40 CFR 70.7(a) should address the final FIP requirements.

As was the case in the CSAPR, the CSAPR Update and the Revised CSAPR Update, the new and amended FIPs impose no independent permitting requirements and the title V permitting process will impose no additional burden on sources already required to be permitted under title V.

F. Relationship to Other Emissions Trading and Ozone Transport Programs

1. NO_X SIP Call

States affected by both the NO_X SIP Call for the 1979 ozone NAAQS and any final ozone season requirements established upon finalization of this proposed rule for the 2015 ozone NAAQS will be required to comply with the requirements of both rules. EPA is proposing to require NO_X ozone season emissions reductions from EGUs larger than 25 MWe in many of the NO_X SIP Call states, and at greater stringency than required by the NO_X SIP Call, by requiring the EGUs to participate in the CSAPR NO_X Ozone Season Group 3 Trading Program. Therefore, this proposed rule, if finalized, would satisfy the requirements of the NO_X SIP Call for these large EGUs.

In the Revised CSAPR Update, the EPA finalized the option for any NO_X SIP Call state that was also subject to the Revised CSAPR Update to voluntarily submit a SIP revision to expand the applicability of the Group 3 trading program to include all NO_X Budget Trading Program units, which in addition to large EGUs also include large non-EGU boilers and combustion turbines with a maximum design heat input greater than 250 mmBtu/hr. As part of such a SIP revision, the state

[328] The EPA has also issued a guidance document and template that includes instructions for how to incorporate the applicable requirements into a source's Title V permit. *See* Memorandum dated May 13, 2015, from Anna Marie Wood, Director, Air Quality Policy Division, and Reid P. Harvey, Director, Clean Air Market Division, EPA, to Regional Air Division Directors, Subject: ''Title V Permit Guidance and Template for the Cross-State Air Pollution Rule'' (''2015 Title V Guidance''), available at *https://www.epa.gov/sites/default/files/2016-10/documents/csapr_title_v_permit_guidance.pdf.*

[329] Id.

[330] *https://www.epa.gov/airmarkets/part-75-petition-responses.*

[331] A permit is reopened for cause if any new applicable requirements (such as those under a FIP) become applicable to an affected source with a remaining permit term of 3 or more years. If the remaining permit term is less than 3 years, such new applicable requirements will be added to the permit during permit renewal. *See* 40 CFR 70.7(f)(1)(I) and 71.7(f)(1)(I).

would be allowed to issue additional emissions allowances capped at a level intended to preserve the stringency of the Group 3 trading program. In today's proposed rule, the EPA is not proposing any changes to this provision of the Group 3 trading program.[332]

2. Acid Rain Program

This proposed rule, if finalized, would not affect any Acid Rain Program requirements. Any Title IV sources that are subject to provisions of this proposed rule would still need to continue to comply with all Acid Rain provisions. Acid Rain Program SO_2 and NO_X requirements are established independently in Title IV of the CAA and will continue to apply independently of this proposed rule's provisions. Acid Rain sources will still be required to comply with Title IV requirements, including the requirement to hold Title IV allowances to cover SO_2 emissions after the end of a compliance year.

3. Other Current Emissions Trading Programs

This proposed rule, if finalized, would not substantively affect any provisions of the CSAPR NO_X Annual, CSAPR SO_2 Group 1, CSAPR SO_2 Group 2, CSAPR NO_X Ozone Season Group 1, or CSAPR NO_X Ozone Season Group 2 trading programs for sources that continue to participate in those programs except with regard to the schedule for EPA to record certain allowance allocations, as discussed in Section VII.B.12 of this proposed rule. In addition, certain revisions are proposed to the CSAPR NO_X Ozone Season Group 2 Trading Program regulations to address the proposed transition of sources in eight states from that program to the CSAPR NO_X Ozone Season Group 3 Trading Program, as discussed in Section VII.B.11 of this proposed rule. Sources that are subject to any of the CSAPR trading programs will still be required to comply with all requirements, including the requirement to hold allowances to cover emissions after the end of a control period.

[332] In the CSAPR Update, the EPA finalized an identical option allowing NO_X SIP Call states to expand applicability of the Group 2 trading program to cover certain non-EGUs. If the geographic expansion of the Group 3 trading program proposed in this rulemaking is finalized as proposed, no NO_X SIP Call states would continue to be covered by the Group 2 trading program. Because the provision allowing NO_X SIP Call states to expand applicability of the Group 2 trading program to include such non-EGUs would therefore be obsolete, the EPA is proposing to remove the provision.

VIII. Environmental Justice Analytical Considerations and Stakeholder Outreach and Engagement

Consistent with EPA's commitment to integrating environmental justice in the agency's actions, and following the directives set forth in multiple Executive Orders, the Agency has analyzed the impacts of this proposed rule on communities with environmental justice concerns and engaged with stakeholders representing these communities to seek input and feedback. Executive Order 12898 is discussed in Section XI.J of this proposed rule and analytical results are available in Chapter 7 of the RIA.

A. Introduction

Executive Order 12898 directs EPA staff to identify the populations of concern who are most likely to experience unequal burdens from environmental harms; specifically, minority populations, low-income populations, and indigenous peoples.[333] Additionally, Executive Order 13985 is intended to advance racial equity and support underserved communities through federal government actions.[334] The EPA defines environmental justice as the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income, with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. EPA further defines the term fair treatment to mean that "no group of people should bear a disproportionate burden of environmental harms and risks, including those resulting from the negative environmental consequences of industrial, governmental, and commercial operations or programs and policies." [335] In recognizing that minority and low-income populations often bear an unequal burden of environmental harms and risks, EPA continues to consider ways of protecting them from adverse public health and environmental effects of air pollution.

B. Analytical Considerations

EPA's environmental justice technical guidance [336] states that "[t]he analysis of potential EJ concerns for regulatory actions should address three questions:

1. Are there potential environmental justice concerns associated with environmental stressors affected by the regulatory action for population groups of concern in the baseline?
2. Are there potential environmental justice concerns associated with environmental stressors affected by the regulatory action for population groups of concern for the regulatory option(s) under consideration?
3. For the regulatory option(s) under consideration, are potential environmental justice concerns created or mitigated compared to the baseline?"

To address these questions in EPA's first quantitative EJ analysis in the context of a transport rule, the EPA developed a unique analytical approach that considers the purpose and specifics of the proposed rulemaking, as well as the nature of known and potential exposures and impacts. However, due to data limitations, it is possible that our analysis failed to identify disparities that may exist, such as potential environmental justice characteristics (*e.g.,* unemployed), environmental impacts (*e.g.,* other ozone metrics), and more granular spatial resolutions (*e.g.,* neighborhood scale) that were not evaluated.

For the proposed rule, we employ two types of analytics to respond to the above three questions: Proximity analyses and exposure analyses. Both types of analyses can inform whether there are potential EJ concerns for population groups of concern in the baseline (question 1).[337] In contrast, only the exposure analyses, which are based on future air quality modeling, can inform whether there will be potential EJ concerns after implementation of the regulatory options under consideration (question 2) and whether potential EJ concerns will be created or mitigated compared to the baseline (question 3). While the exposure analysis can respond to all three questions, it should be noted that exposure is limited to a single ozone metric, the maximum daily 8-hour average, averaged across the April through September warm season (AS–MO3). This ozone metric likely smooths potential daily ozone gradients and is not directly relatable to the National Ambient Air Quality Standard (NAAQS). Additionally, the ozone exposure analytic results are provided in two formats: Aggregated and distributional. The aggregated results provide an overview of potential ozone exposure differences across populations at the national- and state-levels, while the distributional results show detailed

[333] 59 FR 7629, February 16, 1994.

[334] 86 FR 7009, January 20, 2021.

[335] *https://www.epa.gov/environmentaljustice.*

[336] U.S. Environmental Protection Agency (EPA), 2015. Guidance on Considering Environmental Justice During the Development of Regulatory Actions.

[337] The baseline for proximity analyses is current population information (*e.g.,* 2021), whereas the baseline for ozone exposure analyses are the future years in which the regulatory options will be implemented (*e.g.,* 2023 and 2026).

information about ozone concentrations experienced by everyone within each population.

In Chapter 7 of the RIA we utilize the two types of analytics to address the three EJ questions by quantitatively evaluating (1) the proximity of affected facilities to potentially disadvantaged populations (Section 7.3.1), (2) the potential for disproportionate total ozone concentrations in the baseline across different demographic groups (Sections 7.4.1.1 and 7.4.2.1), and (3) how regulatory alternatives differentially impact the ozone concentration changes experienced by different demographic populations (Sections 7.4.1.2 and 7.4.2.2). Each of these analyses depends on mutually exclusive assumptions, was performed to answer separate questions, and is associated with unique limitations and uncertainties.

Baseline demographic proximity analyses can be relevant for identifying populations that may be exposed to local pollutants, such as NO_2 emitted from affected sources in this proposed rule. However, such analyses are less useful here as they do not account for the potential impacts of this proposed rule on long-range ozone concentration changes. The baseline demographic proximity analysis presented in the RIA finds larger percentages of Hispanic individuals, Black individuals, people below the poverty level, people with less educational attainment, and people linguistically isolated living within 5 km and 10 km of an affected EGU, compared to national averages. It also finds larger percentages of people below the poverty level and with less educational attainment living within 5 km and 10 km of an affected non-EGU. Separately, the tribal proximity analysis finds multiple tribes and unique tribal lands located within 50 miles of an affected facility. These results do not in themselves demonstrate disproportionate impacts of affected facilities in the baseline but could suggest that emission reductions from this proposed rule may be responsive to potential local air quality concerns of nearby communities.

Whereas the proximity analyses are limited to evaluating local pollutants under baseline scenarios (question 1), the ozone exposure analyses can provide insight into all three EJ questions with regard to AS–MO3 concentrations. Even though both the proximity and ozone exposure analyses can improve understanding of baseline EJ concerns (question 1), the two should not be directly compared. This is because the demographic proximity analysis does not include air quality information and is based on current, not future, population information.

Importantly, the baseline analysis of AS–MO3 ozone concentrations responds to question 1 from EPA's environmental justice technical guidance document more directly than the proximity analyses, as it evaluates a form of the environmental stressor targeted by the regulatory action. Baseline AS–MO3 analyses show that certain populations, such as American Indians, Hispanics, and Asians, may experience somewhat higher AS–MO3 concentrations compared to the national average. The less educated and children may also experience higher concentrations compared to the national average, but to a lesser extent. Conversely, Black populations may experience lower AS–MO3 concentrations than the national average. Therefore, also in response to question 1, there likely are potential environmental justice concerns associated with ozone exposures affected by the regulatory action for population groups of concern in the baseline. However, these baseline exposure results have not been fully explored and additional analyses are likely needed to understand potential implications.

The ozone exposure analysis evaluates the impacts of the proposed rule on future ozone concentrations after rule implementation. When comparing across the policy, more-, and less-stringent regulatory alternatives, AS–MO3 concentrations are reduced across all populations evaluated in both future years and across both EGUs and non-EGUs. In other words, we expect that populations experiencing disproportionate AS–MO3 exposures in the baseline will experience similar disproportionate AS–MO3 exposures under the proposed rulemaking, although to a lesser absolute extent as the action described in this proposed rule is expected to lower ozone in many areas, including residual ozone nonattainment areas, and thus alleviate some pre-existing health risks of ozone across all populations evaluated. Therefore, in response to question 2, we expect that there will be potential EJ concerns with regard to AS–MO3 concentrations after implementation of the regulatory options under consideration.

Question 3 asks whether potential EJ concerns will be created or mitigated as compared to the baseline. As the RIA estimates disproportionate AS–MO3 exposures in the baseline and similar reductions in all population evaluated, we do not predict that potential EJ concerns related to AS–MO3 concentrations will be created or mitigated as compared to the baseline (question 3).

The ozone exposure results should not be extrapolated to ozone metrics other than AS–MO3. Detailed environmental justice analytical results can be found in Chapter 7 of the RIA.

C. Outreach and Engagement

Prior to this proposed rule, EPA initiated a public outreach effort to gather input from stakeholder groups likely to be interested in this proposed rule. Specifically, the EPA hosted an environmental justice webinar on October 26, 2021, to share information about the proposed rule and solicit feedback about potential environmental justice considerations. The webinar was attended by over 180 individuals representing state governments, federally recognized tribes, environmental NGOs, higher education institutions, industry, and the EPA.[338] Participants were invited to comment during the webinar or provide written comments to a pre-regulatory docket. The webinar was recorded and distributed to attendees after the event. Some of the key issues raised by stakeholders during the webinar and in the pre-proposal comments are described below.

Daily emissions rate limits. Several commenters asserted that cap and trade programs with seasonal limits on overall NO_X emissions do not prevent facilities from running their controls inefficiently on high ozone days. These commenters recommended that facilities linked to downwind ozone problems comply with daily rate limits to ensure that emissions reductions occur on days when ozone is highest. The commenters noted that daily limits could particularly benefit environmental justice communities located near facilities and would also benefit those located downwind.

Regulation of other sources. Several commenters asserted that the EPA should consider regulation of sources other than EGUs and sources of NO_X in rulemakings pertaining to issues of ozone transport. For example, some commenters asserted that the EPA should regulate emissions from non-EGUs, mobile sources, and sources of VOCs.

Environmental justice analysis and methodology in rulemakings. Several commenters offered recommendations to improve environmental justice analysis and methodology in rulemakings that address air pollution.

[338] This does not constitute EPA's tribal consultation under E.O. 13175, which is described in Section XI.F of this proposed rule.

One commenter recommended that the EPA should broadly: (1) Identify communities of interest, based on the number of and proximity to polluting facilities; (2) integrate demographic factors to discern social, economic, and racial disparities in these areas; (3) consider the community's particular vulnerabilities and sensitivities to health harms and risks, and exposure to cumulative health harms and risks; and (4) reach out to the community members near such facilities themselves to gain tangible, lived experiences across their lifetimes. The commenter also suggested that the EPA should build off factors identified in existing environmental justice screening tools, including EPA EJSCREEN and California's CalEnviroScreen. One commenter noted that in developing environmental justice analyses, the EPA should consider and address the need for regulatory certainty, including the need for clear regulatory definitions of environmental justice areas and clear requirements for those areas.

Environmental justice stakeholder outreach in rulemakings. Some commenters asserted that the EPA could improve stakeholder outreach in the rulemaking process. For example, one commenter noted that during the development of a rule proposal, the EPA could more directly reach out to all potentially impacted environmental justice communities, be more prepared to answer questions about the rule proposal, and be more aware of holidays when establishing comment periods.

Additionally, some comments touched on issues that are also relevant to other EPA policies and programs. For example, some commenters asserted that the EPA should base air pollutant transport policy more on monitored data rather than modeling data to promptly address air pollution in areas where current monitoring data indicates an exceedance of the NAAQS. Other commenters recommended that the EPA consider strengthening cost thresholds for Reasonably Available Control Technology (RACT), a program that is applicable to certain existing sources in non-attainment areas.

In addition to the engagement conducted prior to this proposed rule, EPA is providing the public, including those communities disproportionately impacted by the burdens of pollution, opportunities to engage in the EPA's public comment period for this proposed rule, including by hosting a public hearing. This public hearing will occur according to the schedule identified in the Public Participation section of this proposed rule.

IX. Costs, Benefits, and Other Impacts of the Proposed Rule

In the Regulatory Impact Analysis for the proposed Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standards (RIA), EPA estimated the benefits, compliance costs, and emissions changes that may result from the proposed rule for the analysis period 2023 to 2042. The estimated benefits and compliance costs are presented in detail in the RIA accompanying this proposed rule. EPA notes that for EGUs the estimated benefits and compliance costs are directly associated with generation shifting to minimize costs; fully operating existing SCRs during ozone season; fully operating existing SNCRs during ozone season; installing state-of-the-art combustion controls; imposing backstop emission rate limits on certain units that lack SCR controls; and unit-level decisions to retrofit or retire. EPA also notes that for non-EGUs the estimated benefits and compliance costs are directly associated with installing controls to meet the NO_X emissions limits presented in Section I.B above.

For EGUs, EPA analyzed this proposed rule's emission budgets using uniform control stringency represented by $1,800 per ton of NO_X (2016$) in 2023 and $11,000 per ton of NO_X (2016$) in 2026. EPA also analyzed a more and a less stringent alternative. The more and less stringent alternatives differ from the proposed rule in that they set different NO_X ozone season emission budgets for the affected EGUs and different dates for compliance with backstop emission rate limits.

For non-EGUs, EPA analyzed this proposed rule using a marginal cost threshold of up to $7,500 per ton (2016$) for 2026 for the following emissions units and industries: Reciprocating internal combustion engines in Pipeline Transportation of Natural Gas; kilns in Cement and Cement Product Manufacturing; boilers and furnaces in Iron and Steel Mills and Ferroalloy Manufacturing; furnaces in Glass and Glass Product Manufacturing; and high-emitting boilers in Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mills. The less stringent alternative assumes there are emissions limits for all emission units from the proposal except for high-emitting boilers in Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mills. The more stringent alternative assumes emissions limits for all emission units from the proposed rule and all boilers, not just high-emitting boilers, in Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mills.

Table IX–1 provides the projected 2023 through 2027, 2030, 2035, and 2042 EGU emission reductions for the evaluated regulatory control alternatives. For additional information on emissions changes, *see* Table 4.6 and Table 4–7 in Chapter 4 of the RIA.

TABLE IX–1—EGU OZONE SEASON NO_X EMISSIONS CHANGES AND ANNUAL EMISSIONS REDUCTIONS (TONS) FOR NO_X, SO_2, $PM_{2.5}$, AND CO_2 FOR THE REGULATORY CONTROL ALTERNATIVES FROM 2023–2042

	Proposed rule	Less stringent alternative	More stringent alternative
2023:			
NO_X (ozone season)	6,000	6,000	7,000
NO_X (annual)	10,000	10,000	10,000
SO_2 (annual) *	....	1,000	2,000
CO_2 (annual, thousand metric)	....	....	....
$PM_{2.5}$ (annual)	....	....	....
2024:			
NO_X (ozone season)	26,000	14,000	29,000
NO_X (annual)	42,000	22,000	45,000
SO_2 (annual)	42,000	20,000	43,000
CO_2 (annual, thousand metric)	18,000	10,000	19,000
$PM_{2.5}$ (annual)	4,000	1,000	4,000
2025:			

TABLE IX–1—EGU OZONE SEASON NO_X EMISSIONS CHANGES AND ANNUAL EMISSIONS REDUCTIONS (TONS) FOR NO_X, SO_2, $PM_{2.5}$, AND CO_2 FOR THE REGULATORY CONTROL ALTERNATIVES FROM 2023–2042—Continued

	Proposed rule	Less stringent alternative	More stringent alternative
NO_X (ozone season)	46,000	22,000	51,000
NO_X (annual)	73,000	33,000	80,000
SO_2 (annual)	83,000	39,000	84,000
CO_2 (annual, thousand metric)	37,000	19,000	38,000
$PM_{2.5}$ (annual)	9,000	2,000	9,000
2026:			
NO_X (ozone season)	47,000	32,000	53,000
NO_X (annual)	81,000	55,000	87,000
SO_2 (annual)	106,000	76,000	108,000
CO_2 (annual, thousand metric)	40,000	26,000	42,000
$PM_{2.5}$ (annual)	9,000	5,000	9,000
2027:			
NO_X (ozone season)	49,000	42,000	54,000
NO_X (annual)	88,000	76,000	95,000
SO_2 (annual)	129,000	113,000	131,000
CO_2 (annual, thousand metric)	43,000	34,000	46,000
$PM_{2.5}$ (annual)	10,000	7,000	10,000
2030:			
NO_X (ozone season)	52,000	52,000	57,000
NO_X (annual)	96,000	98,000	100,000
SO_2 (annual)	104,000	100,000	103,000
CO_2 (annual, thousand metric)	50,000	45,000	50,000
$PM_{2.5}$ (annual)	9,000	9,000	9,000
2035:			
NO_X (ozone season)	49,000	50,000	52,000
NO_X (annual)	90,000	93,000	93,000
SO_2 (annual)	96,000	93,000	98,000
CO_2 (annual, thousand metric)	38,000	36,000	38,000
$PM_{2.5}$ (annual)	11,000	12,000	10,000
2042:			
NO_X (ozone season)	47,000	47,000	48,000
NO_X (annual)	70,000	75,000	71,000
SO_2 (annual)	54,000	50,000	54,000
CO_2 (annual, thousand metric)	25,000	23,000	24,000
$PM_{2.5}$ (annual)	8,000	9,000	8,000

*SO_2 emissions reductions under the proposed rule are 350 tons and rounded to zero. SO_2 emissions reductions under the less stringent alternative are 507 tons and rounded to 1,000 tons. SO_2 emissions reductions are 1,699 tons under the more stringent alternative and rounded to 2,000 tons. Given the rounding, the difference between the reductions under the proposed rule and the less stringent alternative is approximately 160 tons.

Table IX–2 below provides a summary of the ozone season emissions for non-EGUs for the 23 states subject to the proposed non-EGU emissions limits starting in 2026, along with the estimated ozone season reductions for 2026 for the proposed rule and the less and more stringent alternatives. The analysis in the RIA assumes that the estimated reductions in 2026 will be the same in later years.

TABLE IX–2—OZONE SEASON (OS) NO_X EMISSIONS AND EMISSIONS REDUCTIONS (TONS) FOR NON-EGUS FOR THE PROPOSED RULE AND THE LESS AND MORE STRINGENT ALTERNATIVES *

* In the non-EGU screening assessment for 2026, EPA estimated emissions reduction potential from the non-EGU industries and emissions units. In the screening assessment, EPA used CoST to identify emissions units, emissions reductions, and associated compliance costs to evaluate the effects of potential non-EGU emissions control measures and technologies. CoST is designed to be used for illustrative control strategy analyses (*e.g.,* NAAQS regulatory impact analyses) and not for unit-specific, detailed engineering analyses. The estimates from CoST identify proxies for (1) non-EGU emissions units that have emissions reduction potential, (2) potential controls for and emissions reductions from these emissions units, and (3) control costs from the potential controls on these emissions units. The control cost estimates do not include monitoring, recordkeeping, reporting, or testing costs. This screening assessment is not intended to be, nor take the place of, a unit-specific detailed engineering analysis that fully evaluates the feasibility of retrofits for the emissions units, potential controls, and related costs.

[a] EPA determined that the 2019 inventory was appropriate because it provided a more accurate prediction of potential near-term emissions reductions. The analysis in the RIA assumes that the 2019 ozone season emissions will be the same in 2026 and later years.

For EGUs, the EPA analyzed ozone season NO_X emission reductions and the associated costs to the power sector using the Integrated Planning Model (IPM) and its underlying data and inputs. For non-EGUs, the EPA analyzed ozone season NO_X emission reductions and the associated costs for 2026 in the Non-EGU Screening Assessment memorandum. Table IX–3 reflects the estimates of the changes in the cost of supplying electricity for the regulatory control alternatives for EGUs and estimates of complying with the emissions limits for non-EGUs. For EGUs, compliance costs are negative in 2023. While seemingly counterintuitive, estimating negative compliance costs in a single year is possible given IPM's objective function is to minimize the discounted net present value (NPV) of a stream of annual total cost of generation over a multi-decadal time period. As such the model may undertake a compliance pathway that pushes higher costs later into the forecast period, since future costs are discounted more heavily than near term costs. This can result in a policy scenario showing single year costs that are lower than the Baseline, but over the entire forecast horizon, the policy scenario shows higher costs. For a detailed description of these cost trends, please see Chapter 4, Section 4.5.2 of the RIA. For a detailed description of the methods and results from Non-EGU Screening Assessment memorandum, see Chapter 4, Sections 4.4 and 4.5.2 of the RIA.

TABLE IX–3—TOTAL ESTIMATED COMPLIANCE COSTS (MILLION 2016$), 2023–2042

	Proposed rule	Less-stringent alternative	More-stringent alternative
2023:			
EGUs	−209	−173	−178
Non-EGUs	....	....	....
Total	−209	−173	−178
2026:

Non-EGUs	411	357	445
Total	1,321	2,114	1,446

Tables IX–4 and IX–5 report the estimated economic value of avoided premature deaths and illness in each year relative to the baseline along with the 95% confidence interval. In each of these tables, for each discount rate and regulatory control alternative, multiple benefits estimates are presented reflecting alternative ozone and $PM_{2.5}$ mortality risk estimates. For additional information on these benefits, see Chapter 5 of the RIA.

TABLE IX–4—ESTIMATED DISCOUNTED ECONOMIC VALUE OF AVOIDED OZONE AND $PM_{2.5}$-ATTRIBUTABLE PREMATURE MORTALITY AND ILLNESS FOR THE PROPOSED POLICY SCENARIOS IN 2023

[95% Confidence interval; millions of 2016$] [a] [b]

Disc. rate	Pollutant	Proposal	More stringent alternative	Less stringent alternative
3%	Ozone Benefits	$57 ($15 to $120) [c] *and* $460 ($51 to $1,200) [d].	$65 ($17 to $140) [c] *and* $530 ($59 to $1,400) [d].	$57 ($15 to $120) [c] *and* $460 ($51 to $1,200). [d]
	PM Benefit Per Ton (BPT)s.	$44 *and* $45	$190 *and* $190	$59 *and* $60.
	Ozone Benefits plus PM BPTs.	$100 ($59 to $160) [c] *and* $500 ($96 to $1,200) [d].	$250 ($200 to $330) [c] *and* $720 ($250 to $1,600) [d].	$120 ($74 to $180) [c] *and* $520 ($110 to $1,300). [d]
7%	Ozone Benefits	$51 ($9.6 to 110) [c] *and* $410 ($42 to $1,100) [d].	$58 ($11 to $130) [c] *and* $480 ($49 to $1,300) [d].	$51 ($9.6 to $110) [c] *and* $410 ($42 to $1,100). [d]
	PM BPTs	$40 *and* $41	$170 *and* $170	$53 *and* $54.
	Ozone Benefits plus PM BPTs.	$90 ($49 to $150) [c] *and* $450 ($83 to $1,100) [d].	$230 ($180 to $300) [c] *and* $650 ($220 to $1,400) [d].	$100 ($63 to $170) [c] *and* $470 ($97 to $1,100). [d]

[a] Values rounded to two significant figures. The two benefits estimates are separated by the word "and" to signify that they are two separate estimates. The estimates do not represent lower- and upper-bound estimates and should not be summed.
[b] We estimated ozone benefits for changes in NO_X for the ozone season and changes in $PM_{2.5}$ and $PM_{2.5}$ precursors for EGUs in 2023. This table does not include benefits from reductions for non-EGUs because reductions from these sources are not expected prior to 2026 when the proposed standards would become effective.
[c] Using the pooled short-term ozone exposure mortality risk estimate.
[d] Using the long-term ozone exposure mortality risk estimate.

TABLE IX–5—ESTIMATED DISCOUNTED ECONOMIC VALUE OF AVOIDED OZONE AND $PM_{2.5}$-ATTRIBUTABLE PREMATURE MORTALITY AND ILLNESS FOR THE PROPOSED POLICY SCENARIO IN 2026

[95% Confidence interval; millions of 2016$] [a] [b]

Disc. rate	Pollutant	Proposal	More stringent alternative	Less stringent alternative
3%	Ozone Benefits	$1,200 ($310 to $2,600) [c] *and* $10,000 ($1,100 to $26,000) [d].	$1,300 (340 to $2,900) [c] *and* $11,000 ($1,200 to $29,000) [d].	$830 ($210 to $1,800) [c] *and* $6,900 ($760 to $18,000). [d]
	PM BPTs	$8,100 *and* $8,300	$7,800 *and* $7,900	$3,400 *and* $3,500.
	Ozone Benefits plus PM BPTs.	$9,300 ($8,400 to $11,000) [c] *and* $18,000 ($9,400 to $35,000) [d].	$9,100 ($8,100 to $11,000) [c] *and* $19,000 ($9,200 to $37,000) [d].	$4,300 ($3,700 to $5,200) [c] *and* $10,000 ($4,300 to $22,000). [d]
7%	Ozone Benefits	$1,100 ($200 to $2,400) [c] *and* $9,000 ($920 to $24,000) [d].	$1,200 ($220 to $2,700) [c] *and* $10,000 ($1,000 to $26,000) [d].	$740 ($140 to $1,700) [c] *and* $6,200 ($630 to $16,000). [d]
	PM BPTs	$7,300 *and* $7,400	$7,000 *and* $7,100	$3,100 *and* $3,200.
	Ozone Benefits plus PM BPTs.	$8,400 ($7,500 to $9,700) [c] *and* $16,000 ($8,300 to $31,000) [d].	$8,200 ($7,200 to $9,700) [c] *and* $17,000 ($8,200 to $34,000) [d].	$3,800 ($3,200 to $4,800) [c] *and* $9,300 ($3,800 to $19,000). [d]

[a] Values rounded to two significant figures. The two benefits estimates are separated by the word "and" to signify that they are two separate estimates. The estimates do not represent lower- and upper-bound estimates and should not be summed.
[b] We estimated changes in NO_X for the ozone season and changes in $PM_{2.5}$ and $PM_{2.5}$ precursors in 2026. This table represents changes in EGU and non-EGU ozone season and annual controls.
[c] Sum of ozone mortality estimated using the pooled short-term ozone exposure risk estimate and the Di et al. (2017) long-term $PM_{2.5}$ exposure mortality risk estimate.
[d] Sum of the Turner et al. (2016) long-term ozone exposure risk estimate and the Di et al. (2017) long-term $PM_{2.5}$ exposure mortality risk estimate.

In Tables IX–6, IX–7, and IX–8, EPA presents a summary of the monetized benefits, costs, and net benefits of the proposal and the more and less stringent alternatives for 2023, 2026, and 2030, respectively. The monetized benefits estimates do not include important climate benefits that were not monetized in the RIA. In addition, there are important water quality benefits and health benefits associated with reductions in concentrations of air pollutants other than $PM_{2.5}$ and ozone that are not quantified. We request comment on how to address the climate benefits and other categories of non-monetized benefits of the proposed rule. Discussion of the non-monetized health, climate, welfare, and water quality benefits is found in Chapter 5 of the RIA.

TABLE IX–6—MONETIZED BENEFITS, COSTS, AND NET BENEFITS OF THE PROPOSED AND LESS AND MORE STRINGENT ALTERNATIVES FOR 2023 FOR THE U.S.

[Millions of 2016$] [a] [b]

	Proposed rule	Less stringent alternative	More stringent alternative
Benefits [c] (3%)	$100 and $500	$120 and $520	$250 and $720.
Costs [d]	−$210	−$170	−$180.
Net Benefits	$310 and $710	$290 and $690	$430 and $900.
Benefits [c] (7%)	$90 and $450	$100 and $470	$230 and $650.
Costs [d]	−$210	−$170	−$180
Net Benefits	$300 and $660	$280 and $640	$400 and $820.

[a] We focus results to provide a snapshot of costs and benefits in 2023, using the best available information to approximate social costs and social benefits recognizing uncertainties and limitations in those estimates.
[b] Rows may not appear to add correctly due to rounding.

[c] Monetized benefits include those related to public health associated with reductions in $PM_{2.5}$ and ozone concentrations. The health benefits are associated with several point estimates and are presented at a real discount rate of 3 percent. Several categories of benefits remain unmonetized and are thus not reflected in the table. Non-monetized benefits include important climate benefits from reductions in CO_2 emissions. The U.S. District Court for the Western District of Louisiana has issued an injunction concerning the monetization of the benefits of greenhouse gas emission reductions by EPA and other defendants. *See Louisiana* v. *Biden,* No. 21–cv–01074–JDC–KK (W.D. La. Feb. 11, 2022). Therefore, such values are not presented in the benefit-cost analysis of this proposal conducted pursuant to E.O. 12866. Please see Chapter 5, Section 5.2 of the RIA for more discussion. In addition, there are important unquantified water quality benefits and benefits associated with reductions in other air pollutants.

[d] The costs presented in this table are 2023 annual estimates for each alternative analyzed. An NPV of costs was calculated using a 3.76% real discount rate consistent with the rate used in IPM's objective function for cost-minimization.

TABLE IX–7—MONETIZED BENEFITS, COSTS, AND NET BENEFITS OF THE PROPOSED AND LESS AND MORE STRINGENT ALTERNATIVES FOR 2026 FOR THE U.S.

[Millions of 2016$] [a b]

	Proposed rule	Less stringent alternative	More stringent alternative
Benefits [c] (3%)	$9,300 and $18,000	$4,300 and $10,000	$9,100 and $19,000.
Costs [d]	$1,100	−$49	$1,600.
Net Benefits	$8,200 and $17,000	$4,300 and $10,000	$7,500 and $17,000.
Benefits [c] (7%)	$8,400 and $16,000	$3,800 and $9,300	$8,200 and $17,000.
Costs [d]	$1,100	−$49	$1,600
Net Benefits	$7,300 and $15,000	$9,300 and $3,900	$6,600 and $15,000.

[a] We focus results to provide a snapshot of costs and benefits in 2026, using the best available information to approximate social costs and social benefits recognizing uncertainties and limitations in those estimates.

[b] Rows may not appear to add correctly due to rounding.

[c] Monetized benefits include those related to public health associated with reductions in $PM_{2.5}$ and ozone concentrations. The health benefits are associated with several point estimates and are presented at a real discount rate of 3 percent. Several categories of benefits remain unmonetized and are thus not reflected in the table. Non-monetized benefits include important climate benefits from reductions in CO_2 emissions. The U.S. District Court for the Western District of Louisiana has issued an injunction concerning the monetization of the benefits of greenhouse gas emission reductions by EPA and other defendants. See *Louisiana* v. *Biden,* No. 21–cv–01074–JDC–KK (W.D. La. Feb. 11, 2022). Therefore, such values are not presented in the benefit-cost analysis of this proposal conducted pursuant to E.O. 12866. Please see Chapter 5, Section 5.2 of the RIA for more discussion. In addition, there are important unquantified water quality benefits and benefits associated with reductions in other air pollutants.

[d] The costs presented in this table are 2026 annual estimates for each alternative analyzed. An NPV of costs was calculated using a 3.76% real discount rate consistent with the rate used in IPM's objective function for cost-minimization.

TABLE IX–8—MONETIZED BENEFITS, COSTS, AND NET BENEFITS OF THE PROPOSED AND LESS AND MORE STRINGENT ALTERNATIVES FOR 2030 FOR THE U.S.

(Millions of 2016$) [a b]

	Proposed rule	Less stringent alternative	More stringent alternative
Benefits [c] (3%)	$9,400 and $20,000	$4,300 and $11,000	$9,200 and $21,000.
Costs [d]	$1,600	$1,600	$2,200.
Net Benefits	$7,700 and $18,000	$2,800 and $9,700	$7,000 and $19,000.
Benefits [c] (7%)	$8,400 and $18,000	$3,900 and $10,000	$8,300 and $19,000.
Costs [d]	$1,600	$1,600	$2,200.
Net Benefits	$6,800 and $16,000	$2,300 and $8,400	$6,100 and $16,000.

[a] We focus results to provide a snapshot of costs and benefits in 2030, using the best available information to approximate social costs and social benefits recognizing uncertainties and limitations in those estimates.

[b] Rows may not appear to add correctly due to rounding.

[c] Monetized benefits include those related to public health associated with reductions in $PM_{2.5}$ and ozone concentrations. The health benefits are associated with several point estimates and are presented at a real discount rate of 3 percent. Several categories of benefits remain unmonetized and are thus not reflected in the table. Non-monetized benefits include important climate benefits from reductions in CO_2 emissions. The U.S. District Court for the Western District of Louisiana has issued an injunction concerning the monetization of the benefits of greenhouse gas emission reductions by EPA and other defendants. See *Louisiana* v. *Biden,* No. 21–cv–01074–JDC–KK (W.D. La. Feb. 11, 2022). Therefore, such values are not presented in the benefit-cost analysis of this proposed rule conducted pursuant to E.O. 12866. Please see Chapter 5, Section 5.2 of the RIA for more discussion. In addition, there are important unquantified water quality benefits and benefits associated with reductions in other air pollutants.

[d] The costs presented in this table are 2030 annual estimates for each alternative analyzed. An NPV of costs was calculated using a 3.76% real discount rate consistent with the rate used in IPM's objective function for cost-minimization.

In addition, Table IX–9 presents estimates of the present value (PV) of the monetized benefits and costs and the equivalent annualized value (EAV), an estimate of the annualized value of the net benefits consistent with the present value, over the twenty-year period of 2023 to 2042. The estimates of the PV and EAV are calculated using discount rates of 3 and 7 percent as directed by OMB's Circular A–4 and are presented in 2016 dollars discounted to 2022.

TABLE IX–9—MONETIZED ESTIMATED BENEFITS, COMPLIANCE COSTS, AND NET BENEFITS OF THE PROPOSED RULE AND LESS AND MORE STRINGENT ALTERNATIVES, 2023 THROUGH 2042

(Millions 2016$, discounted to 2022) [a]

	3 Percent discount rate		7 Percent discount rate	
	PV	EAV	PV	EAV
Benefits				
Proposed Rule	$250,000	$17,000	$150,000	$14,000
Less Stringent Alternative	150,000	9,500	88,000	7,800
More Stringent Alternative	270,000	17,000	160,000	14,000
Compliance Costs				
Proposed Rule	22,000	1,500	14,000	1,300
Less Stringent Alternative	20,000	1,300	12,000	1,100
More Stringent Alternative	28,000	1,900	18,000	1,700
Net Benefits				
Proposed Rule	220,000	15,000	130,000	12,000
Less Stringent Alternative	120,000	8,100	70,000	6,600
More Stringent Alternative	230,000	15,000	130,000	12,000

[a] The U.S. District Court for the Western District of Louisiana has issued an injunction concerning the monetization of the benefits of greenhouse gas emission reductions by EPA and other defendants. See *Louisiana* v. *Biden,* No. 21–cv–01074–JDC–KK (W.D. La. Feb. 11, 2022). Therefore, such values are not presented in the benefit-cost analysis of this proposed rule conducted pursuant to E.O. 12866.

As shown in Table IX–9, the PV of the benefits of this proposed rule, discounted at a 3-percent discount rate, is estimated to be about $250,000 million, with an EAV of about $17,000 million. At a 7-percent discount rate, the PV of the benefits is estimated to be $150,000 million, with an EAV of about $14,000 million. The PV of the compliance costs, discounted at a 3-percent rate, is estimated to be about $22,000 million, with an EAV of about $1,500 million. At a 7-percent discount rate, the PV of the compliance costs is estimated to be about $14,000 million, with an EAV of about $1,300 million.

In addition to the analysis of costs and benefits, EPA also estimated the impacts on projected 2023 and 2026 ozone design values that are expected from the EGU and non-EGU control alternatives in this proposed rule. As described above, the alternative scenarios include the proposed rule along with scenarios that reflect less stringent and more stringent alternatives for EGUs and non-EGUs. The projected ozone design values and ozone impacts estimated in 2023 and 2026 for the proposed, less stringent, and more stringent alternatives are provided in Appendix 3B of the RIA. In summary, the differences in the amount of ozone reduction across the three alternatives at individual receptors in 2023 are consistent with the relative changes in NO_X emissions in this year under the different scenarios. Overall, in 2023 the estimated ozone reductions from all three of the alternatives are projected to be less than 0.1 ppb at most receptors. The exceptions are at certain receptors in Connecticut, Illinois, Texas, and Utah where impacts are between 0.1 and 0.2 ppb. In 2026, the largest impacts in the proposed rule are estimated at the two receptors in Texas (*i.e.,* Brazoria County and Harris County), where the average reduction is 1.3 ppb. Elsewhere in 2026, the average reductions for the proposed rule are on the order of 0.5 ppb at receptors in Connecticut, Illinois, and Wisconsin. The average reduction for the four receptors in Utah is approximately 0.3 ppb, while the average reduction at receptors in Colorado and California are approximately 0.2 ppb. Overall, the less stringent alternative provides approximately 0.1 to 0.3 ppb less ppb reduction (*i.e.,* 30 to 40 percent less reduction), on average, compared to the proposed rule at receptors in the East and in Colorado and Utah. The more stringent alternative does not appear to provide any notable additional ozone reductions compared to the proposed rule in all receptor areas, except at receptors in Connecticut and Texas where the average reduction increases by 0.1 ppb and 0.2 ppb with the more stringent alternative, respectively.

Examining the projected average and maximum design values in 2023 at individual receptors for the proposed, less stringent, and more stringent alternatives indicates that three of the receptors included in this impact analysis are projected to change attainment status in 2023 as a result of this proposed rule. Specifically, receptors in Clark County, Nevada, Butte County, California, and Riverside County Californian (Monitor ID: 060650008) are projected to switch from maintenance-only in the 2023 baseline to attainment and the receptor in Harris County, Texas is projected to switch from nonattainment to maintenance-only under any of the alternatives in 2023. In 2026, six of the receptors in this analysis are projected to change attainment status as a result of the emissions reductions in this proposed rule. Specifically, Calaveras County, California, Brazoria County, Texas, and in Kenosha County, Wisconsin (Monitor ID: 550590025) are projected to switch from maintenance-only to attainment in 2026 and a receptor in Riverside County, California (Monitor ID: 060650016) is projected to switch from nonattainment to maintenance under any of the alternatives. The receptor in Douglas County, Colorado and one of the receptors in Cook County, Illinois (Monitor ID: 170310076) are projected to switch from maintenance-only to attainment under the proposed and more stringent alternatives, but these receptors are projected to remain as maintenance-only in the less stringent alternative. The projected design values and additional information on the ozone impact analysis can be found in Appendix 3B of the proposed rule RIA.

X. Summary of Proposed Changes to the Regulatory Text for the Federal Implementation Plans and Trading Programs for EGUs

This section describes the proposed amendments to the regulatory text that would implement the proposed findings and remedy discussed elsewhere in this proposed rule with respect to EGUs. The primary CFR amendments would be revisions to the FIP provisions addressing states' good neighbor obligations related to ozone in 40 CFR part 52 as well as the revisions to the regulations for the CSAPR NO_X Ozone Season Group 3 Trading Program in 40 CFR part 97, subpart GGGGG. In conjunction with the amendments to the Group 3 trading program, the monitoring, recordkeeping, and reporting regulations in 40 CFR part 75 would be amended to reflect the addition of certain new reporting requirements associated with the amended trading program and the administrative appeal provisions in 40 CFR part 78 would be amended to identify certain additional types of appealable decisions of the EPA Administrator under the amended trading program. The proposed provisions to address the transition of the EGUs in certain states from the Group 2 trading program to the Group 3 trading program would be implemented in part through revisions to regulations noted above and in part through revisions to the regulations for the Group 2 trading program in 40 CFR part 97, subpart EEEEE.

In addition to these primary amendments, certain revisions are proposed to the regulations for the other CSAPR trading programs in 40 CFR part 97, subparts AAAAA through EEEEE, and the Texas SO_2 Trading Program in 40 CFR part 97, subpart FFFFF, for conformity with the proposed amended provisions of the Group 3 trading program, as discussed in Section VII.B.12 of this proposed rule. Documents have been included in the docket for this proposed rule showing all of the proposed revisions in redline-strikeout format.

A. Amendments to FIP Provisions in 40 CFR Part 52

The CSAPR, CSAPR Update, and Revised CSAPR Update FIP requirements related to ozone season NO_X emissions are set forth in 40 CFR 52.38(b) as well as other sections of part 52 specific to each covered state. The existing text of § 52.38(b)(1) identifies the trading program regulations in 40 CFR part 97, subparts BBBBB, EEEEE, and GGGGG as constituting the relevant FIP provisions relating to seasonal NO_X emissions and transported ozone pollution. Because the EPA is proposing in this rulemaking to establish new or amended FIP requirements not only for the types of EGUs covered by the trading programs but also for other types of sources, a proposed amendment to § 52.38(b)(1) would clarify that the trading programs constitute the FIP provisions only for the sources meeting the applicability requirements of the trading programs. A parallel clarification would be added to §§ 52.38(a)(1) and 52.39(a) with respect to the CSAPR FIP requirements relating to annual NO_X emissions, SO_2 emissions, and transported fine particulate pollution.

The states whose EGU sources are required to participate in the CSAPR NO_X Ozone Season Group 1, Group 2, and Group 3 trading programs under the FIPs established in CSAPR, the CSAPR Update, and the Revised CSAPR Update, as well as the control periods for which those requirements apply, are identified in § 52.38(b)(2). Proposed amendments to this paragraph would expand the applicability of the Group 3 trading program to sources in the thirteen additional states that the EPA is proposing to add to the Group 3 trading program starting with the 2023 control period and would end the applicability of the Group 2 trading program (with the exception of certain provisions) for sources in eight of the thirteen states after the 2022 control period, as discussed in Section VII.B.2 of this proposed rule.[339] The current subparagraphs within § 52.38(b)(2) would also be renumbered to clarify the organization of the provisions and to facilitate cross-references from other regulatory provisions. Regarding the two states currently participating in the Group 2 trading program through approved SIP revisions that replaced the previous FIPs issued under the CSAPR Update (Alabama and Missouri), a provision indicating that EPA would no longer administer the state trading programs adopted under those SIP revisions after the 2022 control period would be added at § 52.38(b)(16)(ii)(B).

In the Revised CSAPR Update, the EPA established several options for states to revise their SIPs to modify or replace the FIPs applicable to their sources while continuing to use the Group 3 trading program as the mechanism for meeting the states' good neighbor obligations. Existing § 52.38(b)(10), (11), and (12) establish options to replace allowance allocations for the 2022 control period, to adopt an abbreviated SIP revision for control periods in 2023 or later years, and to adopt a full SIP revision for control periods in 2023 or later years, respectively. As discussed in Section VII.D of this proposed rule, the EPA is proposing to retain these SIP revision options and to make them available for all states that would be covered by the Group 3 trading program after the proposed geographic expansion. The option under § 52.38(b)(10) to replace allowance allocations for a single control period would be amended to be available for the 2024 control period, with attendant revisions to the years and dates shown in § 52.38(b)(10) (multiple paragraphs) and (b)(17)(i) as well as the Group 3 trading program regulations, as discussed in Section X.B of this proposed rule. The options under § 52.38(b)(11) and (12) to adopt abbreviated or full SIP revisions would be amended to be available starting with the 2025 control period, with attendant revisions to § 52.38(b)(11)(iii), (b)(12)(iii), and (b)(17)(ii).[340]

The proposed changes with respect to set-asides, the treatment of units in Indian country, and recordation schedules discussed in Section VII.B.9 of this proposed rule, although implemented largely through proposed amendments to the Group 3 trading program regulations, would also be implemented in part through proposed amendments to § 52.38(b)(11) and (12). First, the text in § 52.38(b)(11)(iii)(A) and (b)(12)(iii)(A) identifying the portion of each state trading budget for which a state could establish state-determined allowance allocations would be revised to exclude any allowances in a new unit set-aside, Indian country new unit set-aside, or Indian country existing unit set-aside. Second, the text in § 52.38(b)(12)(vi) identifying provisions that states could not adopt into their SIPs (because the provisions concern regulation of sources in Indian country not subject to a state's CAA implementation planning authority) would be revised to include the provisions of the amended Group 3 trading program addressing allocation and recordation of allowances from all types of set-asides. Third, the text in § 52.38(b)(12)(vii) authorizing the EPA to modify the previous approval of a SIP revision with regard to the assurance provisions ''if and when a covered unit is located in Indian country'' would be revised to account for the fact that at least one covered unit would already be located in Indian country not subject to a state's jurisdiction if the geographic expansion proposed in this rulemaking

[339] Both the current text of § 52.38(b)(2) and the proposed amended text expressly encompass sources in Indian country within the respective states' borders.

[340] No state currently in the Group 3 trading program has submitted a SIP revision to make use of these options in control periods before the control periods in which the options could be used under the proposed amendments.

is finalized. Finally, the text in § 52.38(b)(11)(iii)(B) and (b)(12)(iii)(B) would be revised to amend the deadline for states to submit state-determined allowance allocations to the EPA from June 1 in the third year before the relevant control period to June 1 in the year before the relevant control period.

The proposed transitional provisions discussed in Section VII.B.11 of this proposed rule to convert certain 2017–2022 Group 2 allowances to Group 3 allowances and to recall certain 2023–2024 Group 2 allowances, although promulgated as amendments to the Group 2 trading program regulations, would necessarily be implemented after the end of the 2022 control period. Proposed amendments clarifying that these provisions continue to apply to the relevant sources and holders of allowances notwithstanding the transition of certain states out of the Group 2 trading program after the 2022 control period would be added at § 52.38(b)(14)(iii)(F) and (G). Cross-references clarifying that EPA's allocations of the converted Group 3 allowances would not be subject to modification through SIP revisions would also be added to the existing provisions at § 52.38(b)(11)(iii)(D) and (b)(12)(iii)(D).

The general FIP provisions applicable to all states covered by this proposed rule as set forth in § 52.38(b)(2) would be replicated in the state-specific subparts of 40 CFR part 52 for each of the thirteen states that the EPA is proposing to add to the Group 3 trading program.[341] In each such state-specific CFR subpart, provisions would be added indicating that sources in the state are required to participate in the CSAPR NO_X Ozone Season Group 3 Trading Program with respect to emissions starting in 2023. Provisions would also be added repeating the substance of § 52.38(b)(13)(i), which generally provides that the Administrator's full and unconditional approval of a full SIP revision correcting the same SIP deficiency that is the basis for a FIP promulgated in this rulemaking would cause the FIP to no longer apply to sources subject to the state's CAA implementation planning authority, and § 52.38(b)(14)(ii), which generally provides the EPA with authority to complete recordation of EPA-determined allowance allocations for any control period for which EPA has already started such recordation notwithstanding the approval of a state's SIP revision establishing state-determined allowance allocations.

For each of the eight states that the EPA is proposing to remove from the Group 2 trading program, the current provisions of the state-specific CFR subparts indicating that sources in the state are required to participate in that trading program would be revised to end that requirement with respect to emissions after 2022, and a further provision would be added repeating the substance of § 52.38(b)(14)(iii), which identifies certain provisions that continue to apply to sources and allowances notwithstanding discontinuation of a trading program with respect to a particular state.[342] In addition, for the six states that during their time in the Group 2 trading program have not exercised the option to adopt full SIP revisions to replace the FIPs issued under the CSAPR Update (all but Alabama and Missouri), obsolete provisions concerning the unexercised SIP revision option would be removed.

No amendments with respect to FIP requirements for EGUs would be made to the state-specific CFR subparts for the twelve states whose sources currently participate in the Group 3 trading program[343] except as needed to update cross-references or to implement the proposed changes related to the treatment of Indian country, as discussed in Section X.D of this proposed rule.

B. Amendments to Group 3 Trading Program and Related Regulations

To implement the geographic expansion of the Group 3 trading program and the revised trading budgets that would be established under the new and amended FIPs proposed in this rulemaking, several sections of the Group 3 trading program regulations would be amended. Revisions identifying the applicable control periods, deadlines for certification of monitoring systems, and deadlines for commencement of quarterly reporting for sources not previously covered by the Group 3 trading program would be made at §§ 97.1006(c)(3)(i), 97.1030(b)(1), and 97.1034(d)(2)(i), respectively. Revisions identifying the proposed new or revised budgets and new unit set-asides for the 2023 and 2024 control periods for all covered states would be made at § 97.1010(a)(1) and (b)(1), respectively.

Each of the proposed enhancements to the Group 3 trading program discussed in Section VII.B of this proposed rule would also be implemented primarily through revisions to the trading program regulations. The dynamic budget-setting process discussed in Section VII.B.4 of this proposed rule would be implemented at § 97.1010(a)(2) and (3), and the associated revised process for determining variability limits and assurance levels discussed in Section VII.B.5 of this proposed rule would be implemented at § 97.1010(e). The Group 3 allowance bank recalibration process discussed in Section VII.B.6 of this proposed rule would be implemented at § 97.1026(d). The backstop daily NO_X emissions rate component of the primary emissions limitation discussed in Section VII.B.7 would be implemented at §§ 97.1006(c)(1)(i) and 97.1024(b)(1) and (3), accompanied by the addition of a definition of ''backstop daily NO_X emissions rate'' and modification of the definition of ''CSAPR NO_X Ozone Season Group 3 allowance'' in § 97.1002. The secondary emissions limitation for sources found responsible for exceedances of the assurance levels discussed in Section VII.B.8 of this proposed rule would be implemented at §§ 97.1006(c)(1)(iii) and (iv) and (c)(3)(ii) and 97.1025(c), accompanied by the addition of a definition of ''CSAPR NO_X Ozone Season Group 3 secondary emissions limitation'' in § 97.1002.

The proposed changes relating to set-asides, the treatment of Indian country, unit-level allowance allocations, and recordation schedules discussed in Section VII.B.9 of this proposed rule would be implemented through revisions to multiple sections of §§ 97.1010, 97.1011, 97.1012, and 97.1021, as well as limited revisions to 97.1002 (definition of ''allocate or allocation'') and 97.1006(b)(2). In § 97.1010, paragraphs (b), (c), and (d) would address the amounts for each control period of the new unit set-asides, Indian country new unit set-asides, and Indian country existing unit set-asides, respectively. Paragraphs (c) and (d) would reflect the discontinuation of Indian country new unit set-asides after the 2022 control period and the establishment of Indian

[341] *See* proposed §§ 52.54(b) (Alabama), 52.184(a) (Arkansas), 52.440(d) (Delaware), 52.1240(d) (Minnesota), 52.1824(a) (Mississippi), 52.1326(b) (Missouri), 52.1492 (Nevada), 52.1930(a) (Oklahoma), 52.2240(e) (Tennessee), 52.2283(d) (Texas), 52.2356 (Utah), 52.2587(e) (Wisconsin), and 52.2638(a) (Wyoming).

[342] *See* proposed §§ 52.54(b) (Alabama), 52.184(a) (Arkansas), 52.1824(a) (Mississippi), 52.1326(b) (Missouri), 52.1930(a) (Oklahoma), 52.2240(e) (Tennessee), 52.2283(d) (Texas), and 52.2587(e) (Wisconsin).

[343] *See* proposed §§ 52.731(b) (Illinois), 52.789(b) (Indiana), 52.940(b) (Kentucky), 52.984(d) (Louisiana), 52.1084(b) (Maryland), 52.1186(e) (Michigan), 52.1584(e) (New Jersey), 52.1684(b) (New York), 52.1882(b) (Ohio), 52.2040(b) (Pennsylvania), 52.2440(b) (Virginia), and 52.2540(b) (West Virginia).

country existing unit set-asides starting with the 2023 control period.[344]

The proposed revisions to § 97.1011 would refocus the section exclusively on allocation to ''existing'' units from the portion of each state emissions budget not reserved in a new unit set-aside or Indian country new unit set-aside. In § 97.1011(a), the provision currently in § 97.1011(a)(1) requiring allocations to existing units to be made in the amounts provided in notices of data availability (NODAs) issued by the EPA would be split into two separate provisions, with paragraph (a)(1) applying to existing units in the state and areas of Indian country covered by the state's CAA implementation planning authority and paragraph (a)(2) applying to existing units in areas of Indian country not covered by the state's CAA implementation planning authority.[345] This split would facilitate the submission and approval of SIP revisions by states interested in submitting state-determined allowance allocations for the units over which they exercise CAA implementation authority, while leaving allocations to any units outside their authority to be addressed either by the EPA or by the relevant tribe under an approved tribal implementation plan. The proposed dynamic process for determining default allocations to existing units of allowances from state trading budgets starting with the 2025 control period would be set forth in revised § 97.1011(b), while the current provisions of § 97.1011(b), which concern timing and notice procedures for allocations to new units, would be relocated to § 97.1012. The provisions addressing incorrectly allocated allowances at § 97.1011(c) would be streamlined by relocating the portions applicable to new units to § 97.1012(c). In addition, as discussed in Section VII.B.9.d of this proposed rule, § 97.1011(c)(5) would be revised to provide that, starting with the 2024 control period, any incorrectly allocated allowances recovered after May 1 of the year following the control period would not be reallocated to other units in the state but instead would be transferred to a surrender account.

The proposed revisions to § 97.1012 would retain the section's current focus on allocations to ''new'' units, generally combining the current provisions at § 97.1012 with the current provisions at § 97.1011(b) and (c) that address new units. The text of multiple paragraphs in both § 97.1012(a) and (b) would be revised as needed to reflect the change in treatment of Indian country discussed in Section VII.B.9.a of this proposed rule, under which the new unit set-asides would be used to provide allowance allocations to new units both in non-Indian country and Indian country within the borders of the respective states for control periods starting in 2023.[346] The timing and notice provisions in proposed § 97.1012(a)(13) and (b)(13) are relocated from current § 97.1011(b)(1) and (2). The text of § 97.1012(c), addressing incorrect allocations to new units, is largely relocated from § 97.1011(c) (which addresses incorrect allocations to existing units) and reflects a parallel proposed revision addressing the disposition of recovered allowances, as discussed in Section VII.B.9.d of this proposed rule.

The proposed amendments to § 97.1021 would implement three distinct sets of changes discussed in Sections VII.B.9 and VII.D.1 of this proposed rule. First, revisions to § 97.1021(b) through (e) would replace the previous schedule for recording Group 3 allowances for the 2023 and 2024 control periods established in the Revised CSAPR Update with an updated recordation schedule tailored to the expected timing for issuance of a final rule in this rulemaking. The updated schedule would also reflect elimination of the unused former option for states to provide state-determined allowance allocations for the 2022 control period and the proposed establishment of a substantively equivalent new option for states to provide state-determined allowance allocations for the 2024 control period. Second, revisions to § 97.1021(f) would change the schedule for recording allocations to existing units for future control periods from July 1 of the year three years before the control period to July 1 of the year before the control period. Finally, revisions to § 97.1021(g) through (j) would end recordation for Indian country new unit set-asides after allocations for the 2022 control period, begin recordation for Indian country existing unit set-asides starting with allocations for the 2023 control period, and modify the text to eliminate references to state-determined allocations of allowances from new unit set-asides.

Implementation of the proposed revisions to the Group 3 trading program would also be accomplished in part through amendments to regulations in other CFR parts. In 40 CFR part 75, which contains detailed monitoring, recordkeeping, and reporting requirements applicable to sources covered by the Group 3 trading program, the additional recordkeeping and reporting requirements discussed in Section VII.B.10.b of this proposed rule would be implemented through the addition of §§ 75.72(f) and 75.73(f)(1)(ix) and (x) and revisions to § 75.75, and the procedures for calculating daily total heat input and daily total NO_X emissions and for apportioning NO_X mass emissions monitored at a common stack among the individual units using the common stack would be added at sections 5.3.3, 8.4(c), and 8.5.3 of appendix F to part 75. In 40 CFR part 78, which contains the administrative appeal procedures applicable to decisions of the EPA Administrator under the Group 3 trading program, § 78.1(b)(19) would be amended to list additional decisions made as part of the trading program enhancements that would be appealable under those procedures.

C. Transitional Provisions

As discussed in Section VII.D.11 of this proposed rule, the EPA is proposing several transitional provisions for sources entering the Group 3 trading program. The provisions discussed in Section VII.D.11.a of this proposed rule, concerning the prorating of state emissions budgets, assurance levels, and unit-level allocations for the 2023 control period, would be implemented through the Group 3 trading program regulations. Specifically, the state emissions budgets for the 2023 control period would be prorated according to procedures set out at § 97.1010(a)(1)(ii). Variability limits for the 2023 control period, and the resulting assurance levels, would be computed under § 97.1010(e) from the prorated state emissions budgets. Unit-level

[344] The current § 97.1011(c), which addresses the relationships of set-asides and variability limits to state trading budgets, would be relocated to § 97.1011(f).

[345] An additional provision currently in § 97.1011(a)(1), which clarifies that an allocation or lack of allocation to a unit in a NODA does not constitute a determination by the EPA that the unit is or is not a CSAPR NO_X Ozone Season Group 3 unit, would be relocated to § 97.1011(a)(3). The current § 97.1011(a)(2), which provides for certain existing units that cease operations to receive allocations for their first five control periods of non-operation and provides for the allowances for subsequent control periods to be allocated to the relevant state's new unit set-asides, is inconsistent with the proposed revisions to the set-asides and the default allowance allocation process, as discussed in Section VII.B.9 of this proposed rule, and would be removed as obsolete.

[346] Revisions are also proposed to the text of § 97.1012(a) and (b) for the control periods in 2021 and 2022 consistent with the proposed revisions to the parallel provisions in the regulations for the other CSAPR trading programs, generally calling for allocations to units in areas of Indian country subject to a state's CAA implementation planning authority to be made from the new unit set-asides instead of from the Indian country new unit set-asides.

allocations to existing units for the 2023 control period would be computed from the prorated state emissions budgets according to procedures substantively the same as the procedures codified in § 97.1011(b) for calculating default allocations to existing units for later control periods, as discussed in Section VII.B.9.b of this proposed rule, and would be announced in the notice of data availability issued under § 97.1011(a)(1) and (2) for the 2023 and 2024 control periods.

The remaining transitional provisions would be implemented through the Group 2 trading program regulations. The creation of an additional Group 3 allowance bank for the 2023 control period through the conversion of banked 2017–2022 Group 2 allowances as discussed in Section VII.B.11.b of this document would be implemented at § 97.826(e).[347] Related provisions addressing the use of Group 3 allowances to satisfy after-arising compliance obligations under the Group 2 trading program or the Group 1 trading program would be implemented at §§ 97.826(f)(2) and 97.526(e)(3), respectively, and related provisions addressing recordation of late-arising allocations of Group 1 allowances would be implemented at § 97.526(d)(2)(iii). The recall of Group 2 allowances previously issued for the 2023 and 2024 control periods as discussed in Section VII.B.11.c of this document would be implemented at § 97.811(e).

Decisions of the Administrator related to the allowance bank creation provisions and the allowance recall provisions would be identified as appealable decisions under 40 CFR part 78 through revisions to § 78.1(b)(17)(viii) and (ix).

D. Clarifications and Conforming Revisions

As discussed in Section VII.B.12 of this proposed rule, the EPA is proposing to make revisions to the provisions regarding allowance allocations for units in Indian country in all the CSAPR trading programs so that instead of distinguishing among units based on whether they are or are not located in Indian country, the revised provisions would distinguish among units based on whether they are or are not covered by a state's CAA implementation planning authority. The proposed revisions would be implemented in multiple paragraphs of §§ 97.411(b), 97.412, 97.511(b), 97.512, 97.611(b), 97.612, 97.711(b), 97.712, 97.811(b), and 97.812. The associated revisions to states' options regarding SIP revisions to establish state-determined allowance allocations for units covered by their CAA implementation planning authority would be implemented in multiple paragraphs of §§ 52.38(a) and (b) and 52.39 as well as the state-specific subparts of 40 CFR part 52.

As also discussed in Section VII.B.12 of this proposed rule, the EPA is proposing to revise the recordation schedule for allowance allocations to existing units under all the CSAPR trading programs, as well as the Texas SO_2 Trading Program, so that starting with the 2025 control period the allocation deadline would generally be July 1 of the year before the control period instead of July 1 of the year 3 years before the control period. The revisions would be implemented at §§ 97.421(f)(2), 97.521(f)(2), 97.621(f)(2), 97.721(f)(2), 97.821(f), and 97.921(b)(2).

Certain other revisions to the regulatory text in the FIP and trading program regulations are proposed as non-substantive clarifications. First, in the Group 2 trading program regulations, the paragraphs in § 97.810 setting forth the amounts of state emissions budgets, new unit set-asides, Indian country new unit set-asides, and variability limits for states that the EPA is proposing to transition out of the Group 2 trading program would be modified to indicate that the amounts are applicable under that program only for control periods through 2022.

Second, as noted in Section VII.F.1 of this proposed rule, the existing option for states subject to the NO_X SIP Call to expand applicability of the Group 2 trading program to include certain large non-EGU boilers and combustion turbines would become obsolete if this rule is finalized as proposed because no NO_X SIP Call states would continue to be covered by the Group 2 trading program. The proposed elimination of the obsolete option would be implemented in part through revisions to § 52.38(b)(8) (multiple paragraphs), (b)(9) (multiple paragraphs), (b)(13)(ii), (b)(14)(i)(F), and (b)(16)(i)(B), and in part through revisions to the Group 2 trading program regulations at §§ 97.806(c)(2) and (3), 97.825, and 97.802 (removal of the definitions of ''base CSAPR NO_X Ozone Season Group 2 source'' and ''base CSAPR NO_X Ozone Season Group 2 unit'' and modification of the definitions of ''assurance account'', ''common designated representative'', common designated representative's assurance level'', and ''common designated representative's share'').

Third, to clarify the regulatory text, the EPA is proposing to remove the language in the Group 3 trading program regulations finalized in the Revised CSAPR Update relating to the ''supplemental allowances'' issued for the 2021 control period in current §§ 97.1002 (definition of ''common designated representative's assurance level''), 97.1006(c)(2)(iii), 97.1010(d), and 97.1011(a)(1). In place of the removed language, the EPA proposes to restate the amounts of the state emissions budgets for the 2021 control period in § 97.1010(a)(1)(i) so as to include the amounts of the supplemental allowances in the restated budget amounts. The revised language would be substantively equivalent to and simpler than the current language.

Fourth, in 40 CFR part 75, the EPA proposes to remove obsolete text in § 75.73(c) and (f) to clarify the context for other text that would be added to the section, as discussed in Section X.B.

Finally, the EPA proposes to update cross-references throughout 40 CFR parts 52 and 97 for consistency with the other amendments proposed in this rulemaking.

XI. Statutory and Executive Orders Reviews

Additional information about these statutes and Executive Orders (''E.O.'') can be found at *http://www2.epa.gov/laws-regulations/laws-and-executive-orders*.

A. Executive Order 12866: Regulatory Planning and Review and Executive Order 13563: Improving Regulation and Regulatory Review

This proposed rule is an economically significant regulatory action that was submitted to the Office of Management and Budget (OMB) for review. This proposed rule is in response to a court-ordered legal mandate and proposes to implement EGU and novel non-EGU NO_X ozone season emissions reductions as part of the overall strategy for addressing interstate transport of ozone pollution for the 2015 ozone NAAQS. Any changes made in response to OMB recommendations have been documented in the docket. The EPA prepared an analysis of the potential costs and benefits associated with this proposed rule. This analysis, which is contained in the ''Regulatory Impact Analysis for the Proposed Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standard'' [EPA–452/R–15–009], is available in the docket and is briefly summarized in Section IX of this proposed rule.

[347] The current provisions at § 97.826(e) would be relocated to § 97.826(f)(1) and (3).

B. Paperwork Reduction Act (PRA)

1. Information Collection Request for Electric Generating Units

The information collection activities in this proposed rule have been submitted for approval to the Office of Management and Budget (OMB) under the PRA. The Information Collection Request (ICR) document that the EPA prepared has been assigned EPA ICR number 2709.01. EPA has placed a copy of the ICR in the docket for this rule, and it is briefly summarized here.

EPA is proposing an information collection request (ICR), related specifically to electric generating units (EGU), for the proposed Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Primary Ozone National Ambient Air Quality Standard. The proposed rule would amend the Cross-State Air Pollution Rule (CSAPR) NO_X Ozone Season Group 3 trading program addressing seasonal NO_X emissions in various states. Under the proposed amendments, all EGU sources in the original twelve Group 3 states (Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, New Jersey, New York, Ohio, Pennsylvania, Virginia, and West Virginia) would remain. Additionally, EGU sources in eight states (Alabama, Arkansas, Mississippi, Missouri, Oklahoma, Tennessee, Texas, and Wisconsin) currently covered by the CSAPR NO_X Ozone Season Group 2 Trading Program would transition from the Group 2 program to the revised Group 3 trading program beginning with the 2023 ozone season. Further, sources in five states not currently covered by any CSAPR NO_X ozone season trading program would join the revised Group 3 trading program: Delaware, Minnesota, Nevada, Utah, and Wyoming. In total, EGU sources in 25 states would now be covered by the Group 3 program.

There is an existing ICR (OMB Control Number 2060–0667), that includes information collection requirements placed on EGU sources for the six Cross-State Air Pollution Rule (CSAPR) trading programs addressing sulfur dioxide (SO_2) emissions, annual nitrogen oxides (NO_X) emissions, or seasonal NO_X emissions in various sets of states, and the Texas SO_2 trading program which is modeled after CSAPR. This ICR accounts for the additional respondent burden related to the amendments to the CSAPR NO_X Ozone Group 3 trading program.

The principal information collection requirements under the CSAPR and Texas trading programs relate to the monitoring and reporting of emissions and associated data in accordance with 40 CFR part 75. Other information collection requirements under the programs concern the submittal of information necessary to allocate and transfer emission allowances and the submittal of certificates of representation and other typically one-time registration forms.

Affected sources under the CSAPR and Texas trading programs are generally stationary, fossil fuel-fired boilers and combustion turbines serving generators larger than 25 megawatts (MW) producing electricity for sale. Most of these affected sources are also subject to the Acid Rain Program (ARP). The information collection requirements under the CSAPR and Texas trading programs and the ARP substantially overlap and are fully integrated. The burden and costs of overlapping requirements are accounted for in the ARP ICR (OMB Control Number 2060–0258). Thus, this ICR accounts for information collection burden and costs under the CSAPR NO_X Ozone Season Group 3 trading program that are incremental to the burden and costs already accounted for in both the ARP and CSAPR ICRs.

For most sources already reporting data under the CSAPR NO_X Ozone Season Group 3 or CSAPR NO_X Ozone Group 2 trading programs, there would be no incremental burden or cost, as reporting requirements will remain identical. Certain sources with a common stack configuration and/or those that are large, coal-fired EGUs, will be subject to additional emission reporting requirements under the proposed rule. These sources will need to make a one-time monitoring plan and Data Acquisition and Handling System (DAHS) update to meet the additional reporting requirements. Remaining for assessment of incremental cost and burden are only those sources in the five states not currently reporting data under a CSAPR NO_X Ozone Season program. Sources in Minnesota are already reporting data for the CSAPR NO_X Annual program with almost identical information collection requirements, requiring only a one-time monitoring plan and DAHS update. Most of the affected sources in Delaware, Nevada, Utah, and Wyoming are already reporting data as part of the Acid Rain Program, thus only requiring a monitoring plan and DAHS update as well. Four additional EGUs in Delaware already report data under SIP requirements adopted to meet the NO_X SIP Call and would face identical information requirements under this proposed rule. For the units that already report to EPA under the Acid Rain Program or the NO_X SIP Call, with the exception of any one-time costs to update monitoring plans and DAHS, all information collection costs and burden are already reflected in the previously approved ICRs for those other rules (OMB Control Nos. 2060–0258 and 2060–0445).

In total, there are an estimated 16 units in Delaware, Nevada, Utah, and Wyoming that do not already report data to EPA according to 40 CFR part 75 and that would need to implement one of the Part 75 monitoring methodologies including certification of monitoring systems or implementation of the low mass emissions methodology. These units would also require monitoring plan and DAHS updates. Of these sixteen units, two units would be expected to adopt low mass emissions (LME) as the monitoring method, thirteen would be expected to adopt Appendix D monitoring methods, and one would be expected to adopt CEMS monitoring methods.

Respondents/affected entities: Industry respondents are stationary, fossil fuel-fired boilers and combustion turbines serving electricity generators subject to the CSAPR and Texas trading programs, as well as non-source entities voluntarily participating in allowance trading activities. Potential state respondents are states that can elect to submit state-determined allowance allocations for sources located in their states.

Respondent's obligation to respond: Industry respondents: Voluntary and mandatory (Sections 110(a) and 301(a) of the Clean Air Act).

Estimated number of respondents: EPA estimates that there would be 188 industry respondents.

Frequency of response: On occasion, quarterly, and annually.

Total estimated additional burden: 1,834 hours (per year). Burden is defined at 5 CFR 1320.03(b).

Total estimated additional cost: \$396,520 (per year); includes \$210,571 annualized capital or operation & maintenance costs.

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for the EPA's regulations in 40 CFR are listed in 40 CFR part 9.

Submit your comments on the Agency's need for this information, the accuracy of the provided burden estimates and any suggested methods for minimizing respondent burden to the EPA using the docket identified at the beginning of this rule. You may also send your ICR-related comments to

OMB's Office of Information and Regulatory Affairs via email to *OIRA_submission@omb.eop.gov,* Attention: Desk Officer for the EPA. Since OMB is required to make a decision concerning the ICR between 30 and 60 days after receipt, OMB must receive comments no later than May 6, 2022. The EPA will respond to any ICR-related comments in the final rule.

2. Information Collection Request for Non-Electric Generating Units

The information collection activities in this proposed rule have been submitted for approval to the Office of Management and Budget (OMB) under the PRA. The Information Collection Request (ICR) document that the EPA prepared has been assigned EPA ICR number 2705.01. The EPA has filed a copy of the non-EGU ICR in the docket for this rule, and it is briefly summarized here.

ICR No. 2705.01 is a new request and it addresses the burden associated with new regulatory requirements under the proposed rule. Owners and operators of certain non-Electric Generating Unit (non-EGU) industry stationary sources will potentially modify or install new emission controls and associated monitoring systems to meet the nitrogen oxides (NO_X) emission limits of this proposed rule. The burden in this ICR reflects the new monitoring, calibrating, recordkeeping, reporting and testing activities required by industry and the administrative review conducted by the states of the associated industry activities. This information is being collected to assure compliance with the proposed rule. In accordance with the Clean Air Act Amendments of 1990, any monitoring information to be submitted by sources is a matter of public record. Information received and identified by owners or operators as confidential business information (CBI) and approved as CBI by EPA, in accordance with Title 40, Chapter 1, Part 2, Subpart B, shall be maintained appropriately (see 40 CFR 2; 41 FR 36902, September 1, 1976; amended by 43 FR 39999, September 8, 1978; 43 FR 42251, September 28, 1978; 44 FR 17674, March 23, 1979).

Respondents/affected entities: The respondents/affected entities are the owners/operators of certain non-EGU industry sources in the following industry sectors: Furnaces in Glass and Glass Product Manufacturing; boilers and furnaces in Iron and Steel Mills and Ferroalloy Manufacturing; kilns in Cement and Cement Product Manufacturing; reciprocating internal combustion engines in Pipeline Transportation of Natural Gas; and high-emitting equipment and large boilers in Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mill.

Respondent's obligation to respond: Voluntary and mandatory. (Sections 110(a) and 301(a) of the Clean Air Act). All data that is recorded or reported by respondents is required by the proposed rule, titled ''Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Primary Ozone National Ambient Air Quality Standard: Transport Obligations for non-Electric Generating Units''.

Estimated number of respondents: 489.

Frequency of response: The specific frequency for each information collection activity within the non-EGU ICR is shown at the end of the ICR document in the Tables 1–11. In general, the frequency varies across the monitoring, recordkeeping, and reporting activities. Some recordkeeping such as work plan preparation is a one-time activity whereas engine maintenance recordkeeping is conducted quarterly. Reporting frequency is on a quarterly and semi-annual basis.

Total estimated burden: 51,654 hours (per year). Burden is defined at 5 CFR 1320.3(b).

Total estimated cost: $11,450,000 (average per year); includes $5,467,000 annualized capital or operation & maintenance costs.

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for the EPA's regulations in 40 CFR are listed in 40 CFR part 9.

Submit your comments on the Agency's need for this information from the EGU ICR and non-EGU ICR, the accuracy of the provided burden estimates and any suggested methods for minimizing respondent burden to the EPA using the docket identified at the beginning of this rule. You may also send your ICR-related comments to OMB's Office of Information and Regulatory Affairs via email to *OIRA_submission@omb.eop.gov,* Attention: Desk Officer for the EPA. Since OMB is required to make a decision concerning the ICR between 30 and 60 days after receipt, OMB must receive comments no later than May 6, 2022. The EPA will respond to any ICR-related comments in the final rule.

C. Regulatory Flexibility Act (RFA)

The EPA certifies that this proposed action will not have a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act (RFA). The Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*), as amended by the Small Business Regulatory Enforcement Fairness Act (Pub. L. 104–121), provides that whenever an agency is required to publish a general notice of proposed rulemaking, it must prepare and make available an initial regulatory flexibility analysis, unless it certifies that the proposed rule, if promulgated, will not have a significant economic impact on a substantial number of small entities (5 U.S.C. 605(b)). Small entities include small businesses, small organizations, and small governmental jurisdictions.

In 2026, EPA identified 34 small entities affected by the proposed rule, and of these 6 small entities may experience costs of greater than 1 percent of revenues. Of the 6 small entities projected to have costs greater than 1 percent of revenues, two of them operate in cost-of-service regions and would generally be able to pass any increased costs along to rate-payers. In EPA's modeling, most of the cost impacts for these small entities and their associated units are driven by lower electricity generation relative to the base case baseline. Specifically, four units reduce their generation by significant amounts, driving the bulk of the costs for all small entities. Finally, EPA's decision to exclude units smaller than 25 MW capacity from the proposed FIP, and exclusion of uncontrolled units smaller than 100 MW from backstop emission rate limits has already significantly reduced the burden on small entities by reducing the number of affected small entity-owned units. Further, in 2026 for non-EGUs, there are five small entities, and one small entity is estimated to have a cost-to-sales impact of 1.3 percent of their revenues.

The EPA has determined that an insignificant number of small entities potentially affected by the proposed rule will have compliance costs greater than 1 percent of annual revenues during the compliance period. EPA has concluded that there will be no significant economic impact on a substantial number of small entities (No SISNOSE) for this proposed rule overall. Details of this analysis are presented in Chapter 6 of the RIA, which is in the public docket.

D. Unfunded Mandates Reform Act (UMRA)

This proposed action does not contain an unfunded mandate of $100 million or more as described in UMRA, 2 U.S.C. 1531–1538, and will not significantly or uniquely affect small governments. Note that we expect the proposed rule to potentially have an impact on only one category of government-owned entities (municipality-owned entities). This analysis does not examine potential indirect economic impacts associated with the proposed rule, such as employment effects in industries providing fuel and pollution control equipment, or the potential effects of electricity price increases on government entities. For more information on the estimated impact on government entities, refer to the RIA, which is in the public docket.

E. Executive Order 13132: Federalism

This proposed action does not have federalism implications. If finalized, this proposed action will not have substantial direct effects on the states, on the relationship between the national government and the states, or on the distribution of power and responsibilities among the various levels of government.

F. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments

This proposed action has tribal implications. However, it would neither impose substantial direct compliance costs on federally recognized tribal governments, nor preempt tribal law.

The EPA proposes to make a finding that interstate transport of ozone precursor emissions from 26 upwind states (Alabama, Arkansas, California, Delaware, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Tennessee, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming) is significantly contributing to downwind nonattainment or interfering with maintenance of the 2015 ozone NAAQS in other states, based on projected nitrogen oxides (NO_X) emissions in the 2023 ozone season. EPA is proposing to issue FIP requirements to eliminate interstate transport of ozone precursors from these 26 states that significantly contributes to nonattainment or interferes with maintenance of the NAAQS in other states. Under CAA section 301(d)(4), EPA proposes to extend FIP requirements to apply in Indian country located within the upwind geography of the proposed rule, including Indian reservation lands and other areas of Indian country over which EPA or a tribe has demonstrated that a tribe has jurisdiction. EPA's proposed extension is described further above in Section IV.C.2., *Application of Rule in Indian Country and Necessary or Appropriate Finding.* EPA proposes that all existing and new EGU and non-EGU sources that are located in the 301(d) FIP areas within the geographic boundaries of the covered states, and which would be subject to this rule if located within areas subject to state CAA planning authority, should be included in this rule. This proposed action has tribal implication because of the proposed extension of FIP requirements into Indian country and this proposed rule may have additional tribal implications if a new affected EGU or non-EGU is built in Indian country. To EPA's knowledge, only one existing EGU or non-EGU source is located within the 301(d) FIP areas: The Bonanza Power Plant, an EGU source, located on the Uintah and Ouray Reservation, geographically located within the borders of Utah. In general, tribes have a vested interest in how this proposed rule would affect air quality.

In the Revised CSAPR Update, EPA established default procedures for allocating CSAPR NO_X Ozone Season Group 3 allowances (''Group 3 allowances'') in amounts equal to each state emissions budget for each control period among the sources in the state for use in complying with the Group 3 trading program. Under the current Group 3 trading programs, reserved allowances are made available generally (but not exclusively [348]) to ''new'' units—which for purposes of the Revised CSAPR Update means units commencing commercial operation on or after January 1, 2019—through a ''new unit set-aside'' established for qualifying units in each state and, if areas of Indian country exist within the state's borders, a separate ''Indian country new unit set-aside'' for qualifying units in such Indian country. In this rulemaking, EPA is proposing revisions to each step of the three-step allocation process to better address units in Indian country and to better coordinate the unit-level allocation process with the proposed dynamic budget-setting process.

The EPA hosted an environmental justice webinar on October 26, 2021, that was attended by state regulatory authorities, environmental groups, federally recognized tribes, and small business stakeholders. The EPA will also continue to consult with the government of the Ute Indian Tribe of the Uintah and Ouray Reservation and plans to further consult with any other tribal officials under the EPA Policy on Consultation and Coordination with Indian Tribes early in the process of developing this proposed regulation to solicit meaningful and timely input into its development. The EPA plans to issue tribal consultation letters addressed to 574 tribes in February 2022 after the proposed rule is signed. The EPA will likely facilitate an additional tribal consultation through a webinar before finalizing this proposed rule.

G. Executive Order 13045: Protection of Children From Environmental Health Risks and Safety Risks

The EPA interprets Executive Order 13045 as applying only to those regulatory actions that concern environmental health or safety risks that the EPA has reason to believe may disproportionately affect children, per the definition of ''covered regulatory action'' in section 2–202 of the Executive Order. This action is not subject to Executive Order 13045 because it implements a previously promulgated health-based federal standard. This action's health and risk assessments are contained in Chapter 5 of this RIA. The EPA believes that the ozone-related benefits, $PM_{2.5}$-related benefits, and CO_2-related benefits from this proposed rule will further improve children's health. Additionally, the ozone exposure analysis in Chapter 7 of the RIA suggests that nationally, children (ages 0–17) will experience at least as great a reduction in ozone exposures as adults (ages 18–64) in 2023 and 2026 under all regulatory alternatives of this proposed rulemaking.

H. Executive Order 13211: Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution or Use

This action is not a ''significant energy action'' because it is not likely to have a significant adverse effect on the supply, distribution, or use of energy. EPA has prepared a Statement of Energy Effects for the proposed regulatory contro*l* alternative as follows. The Agency estimates a 1 percent change in retail electricity prices on average across the contiguous U.S. in 2025, a 7.8 percent reduction in coal-fired electricity generation, a 0.15 percent increase in natural gas-fired electricity generation, and a 3.8 percent increase in renewable electricity generation in 2025 as a result of this proposed rule. EPA projects that utility power sector delivered natural gas prices will change by less than 1 percent in 2025. Details of the estimated energy effects are presented in Chapter 4 of the RIA, which is in the public docket.

I. National Technology Transfer and Advancement Act (NTTAA)

This proposed rulemaking does not involve technical standards.

J. Executive Order 12898: Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations

The EPA believes that this action does not have disproportionately high and adverse human health or environmental effects on minority populations, low-income populations and/or indigenous peoples, as specified in Executive Order 12898.[349] The documentation for this decision is contained in Section VIII. *Environmental Justice Analytical Considerations and Stakeholder Outreach and Engagement* of this Proposed rule and in Chapter 7, *Environmental Justice Impacts* of the RIA, which is in the public document. The RIA was prepared under E.O. 12866 *Regulatory Planning and Review* for this proposed rule. While the ozone exposure assessment was subject to several limitations, also described in Chapter 7 of the RIA, overall, ozone concentrations under the proposal, more stringent, and less stringent alternatives are predicted to impact demographic groups very similarly in both future years and across both EGUs and non-EGUs.

Therefore, regarding ozone concentrations, EPA does not find evidence of meaningful environmental justice concerns associated with ozone concentrations after imposition of the proposed regulatory action or alternatives under consideration. We also do not find evidence that any potential environmental justice concerns related to ozone would be meaningfully exacerbated in the regulatory alternatives under consideration, compared to the baseline. Importantly, the action described in this proposed rule is expected to lower ozone in many areas, including residual ozone nonattainment areas, and thus mitigate some pre-existing health risks of ozone across all populations evaluated.

In addition, the EPA provided the public, including those communities disproportionately impacted by the burdens of pollution, opportunities for meaningful engagement with the EPA on this action. A summary of outreach activities conducted by the Agency and what was heard from communities is provided in section VIII of this proposed rule.

K. Determinations Under CAA Section 307(b)(1) and (d)

Section 307(b)(1) of the CAA governs judicial review of final actions by the EPA. This section provides, in part, that petitions for review must be filed in the United States Court of Appeals for the District of Columbia Circuit: (i) When the agency action consists of "nationally applicable regulations promulgated, or final action taken, by the Administrator," or (ii) when such action is locally or regionally applicable, but "such action is based on a determination of nationwide scope or effect and if in taking such action the Administrator finds and publishes that such action is based on such a determination." For locally or regionally applicable final actions, the CAA reserves to EPA complete discretion whether to invoke the exception in (ii).

This proposed action, if finalized, would be "nationally applicable" within the meaning of CAA section 307(b)(1). In the alternative, to the extent a court finds this action to be locally or regionally applicable, the Administrator proposes to exercise the complete discretion afforded to him under the CAA to make and publish a finding that this action is based on a determination of "nationwide scope or effect" within the meaning of CAA section 307(b)(1).[350]

This proposed action, if finalized, will implement the good neighbor provision in 26 states, spanning 8 EPA regions and 10 federal judicial circuits. The proposed action applies a uniform, nationwide analytical method and interpretation of CAA section 110(a)(2)(D)(i)(I) across these states, and the proposed rule is based on a common core of legal, technical, and policy determinations (as explained in further detail in the following paragraph). For these reasons, this proposed action is nationally applicable.

Alternatively, for these same reasons, the Administrator is exercising the discretion afforded to him by the CAA and hereby finds that this proposed action is based on multiple determinations of nationwide scope or effect for purposes of CAA section 307(b)(1).[351] Specifically, the proposed rule is based on a common core of statutory and case law analysis, factual findings, and policy determinations concerning the transport of ozone-precursor pollutants from the different states subject to it, as well as the impacts of those pollutants and the impacts of options to address those pollutants in yet other states. In this proposed action, EPA is applying its 4-step analytic framework to implement the good neighbor provision across these states, using a consistent set of policy and analytical determinations. The proposed determinations include a nationally consistent definition of receptors at Step 1 and findings identifying downwind nonattainment and maintenance receptors; the application of a nationally consistent contribution threshold at Step 2 to determine which states are linked to those receptors and should be further evaluated at Step 3; the use of a nationally consistent multi-factor test at Step 3 to determine which upwind-state contributions to nonattainment and maintenance receptors are "significant" and must be eliminated; and the proposed implementation at Step 4 of a nationally consistent set of emissions control strategies through emissions budgets and an integrated interstate emissions trading program for EGUs, a nationally consistent set of other compliance requirements for EGUs, and a nationally consistent set of enforceable emissions limits and associated compliance requirements for certain non-EGU sources in several industrial sectors across 23 states. Finally, the technical, scientific, and engineering information in support of these proposed determinations relies on a nationally consistent set of air quality modeling analyses and other nationally consistent analytical methods, as set forth elsewhere in this proposed rule and in the relevant supporting documents in the docket for this proposed rule.

Therefore, pursuant to CAA section 307(b), any petitions for review of this action, if and when it is finalized, must be filed in the D.C. Circuit within 60 days from the date such final action is published in the **Federal Register**.

This action is subject to the provisions of section 307(d). CAA section 307(d)(1)(B) provides that section 307(d) applies to, among other things, "the promulgation or revision of an implementation plan by the Administrator under [CAA section 110(c)]." 42 U.S.C. 7407(d)(1)(B). This action, among other things, proposes new federal implementation plans pursuant to the authority of section 110(c). To the extent any portion of this rulemaking, if finalized, is not expressly identified under section 307(d)(1)(B),

[349] 59 FR 7629, February 16, 1994.

[350] In proposing to invoke the exception by making and publishing a finding that this final action is based on a determination of nationwide scope or effect, the Administrator is taking into account a number of policy considerations, including his judgment balancing the benefit of obtaining the D.C. Circuit's authoritative centralized review versus allowing development of the issue in other contexts and the best use of agency resources.

[351] In the report on the 1977 Amendments that revised section 307(b)(1) of the CAA, Congress noted that the Administrator's determination that the "nationwide scope or effect" exception applies would be appropriate for any action that has a scope or effect beyond a single judicial circuit. *See* H.R. Rep. No. 95–294 at 323, 324, reprinted in 1977 U.S.C.C.A.N. 1402–03.

the Administrator determines that the provisions of section 307(d) apply to such final action. *See* CAA section 307(d)(1)(V) (the provisions of section 307(d) apply to ''such other actions as the Administrator may determine'').

List of Subjects

40 CFR Part 52

Environmental protection, Administrative practice and procedure, Air pollution control, Incorporation by reference, Intergovernmental relations, Nitrogen oxides, Ozone, Particulate matter, Sulfur dioxide.

40 CFR Part 75

Environmental protection, Administrative practice and procedure, Air pollution control, Continuous emission monitoring, Electric power plants, Incorporation by reference, Nitrogen oxides, Ozone, Particulate matter, Reporting and recordkeeping requirements, Sulfur dioxide.

40 CFR Part 78

Environmental protection, Administrative practice and procedure, Air pollution control, Electric power plants, Nitrogen oxides, Ozone, Particulate matter, Sulfur dioxide.

40 CFR Part 97

Environmental protection, Administrative practice and procedure, Air pollution control, Electric power plants, Nitrogen oxides, Ozone, Particulate matter, Reporting and recordkeeping requirements, Sulfur dioxide.

Michael Regan,

Administrator.

For the reasons stated in the preamble, parts 52, 75, 78, and 97 of title 40 of the Code of Federal Regulations are proposed to be amended as follows:

PART 52—APPROVAL AND PROMULGATION OF IMPLEMENTATION PLANS

■ 1. The authority citation for part 52 continues to read as follows:

Authority: 42 U.S.C. 7401 *et seq.*

Subpart A—General Provisions

■ 2. Amend § 52.38 by:

■ a. In paragraph (a)(1), removing ''(NO_X), except'' and adding in its place ''(NO_X) for sources meeting the applicability criteria set forth in that subpart, except'';

■ b. In paragraph (a)(4) introductory text, removing ''State's sources, and'' and adding in its place ''State, and'';

■ c. In table 1 to paragraph (a)(4)(i)(B), revising the entry for ''2025 and any year thereafter'';

■ d. In paragraph (a)(5) introductory text, removing ''State (but not sources in any Indian country within the borders of the State), regulations'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, regulations'';

■ e. In table 2 to paragraph (a)(5)(i)(B), revising the entry for ''2025 and any year thereafter'';

■ f. In paragraph (a)(5)(iv), removing ''Indian country within the borders of the State'' and adding in its place ''areas of Indian country within the borders of the State not subject to the State's SIP authority'';

■ g. In paragraph (a)(5)(v), removing ''Indian country within the borders of the State, the'' and adding in its place ''areas of Indian country within the borders of the State not subject to the State's SIP authority, the'';

■ h. Revising paragraphs (a)(6) and (a)(7)(ii);

■ i. In paragraph (a)(8)(iii), removing ''State (but not sources in any Indian country within the borders of the State):'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority:'';

■ j. In paragraph (b)(1), removing ''year), except'' and adding in its place ''year) for sources meeting the applicability criteria set forth in those subparts, except'';

■ k. Redesignating paragraphs (b)(2)(i) and (ii)as paragraphs (b)(2)(i)(A) and (B), respectively, redesignating paragraphs (b)(2)(iii) and (iv) as paragraphs (b)(2)(ii)(A) and (B), respectively, and redesignating paragraph (b)(2)(v) as paragraph (b)(2)(iii)(A);

■ l. In newly redesignated paragraph (b)(2)(ii)(A), removing ''Alabama, Arkansas, Iowa, Kansas, Mississippi, Missouri, Oklahoma, Tennessee, Texas, and Wisconsin.'' and adding in its place ''Iowa and Kansas.'';

■ m. Adding paragraphs (b)(2)(ii)(C) and (b)(2)(iii)(B) and (C);

■ n. In paragraph (b)(3) introductory text, removing ''or (ii)'';

■ o. Revising paragraph (b)(4) introductory text;

■ p. In table 3 to paragraph (b)(4)(ii)(B), revising the entry for ''2025 and any year thereafter'';

■ q. Revising paragraph (b)(5) introductory text;

■ r. In table 4 to paragraph (b)(5)(ii)(B), revising the entry for ''2025 and any year thereafter'';

■ s. In paragraph (b)(5)(v), removing ''Indian country within the borders of the State'' and adding in its place ''areas of Indian country within the borders of the State not subject to the State's SIP authority'';

■ t. In paragraph (b)(5)(vi), removing ''Indian country within the borders of the State, the'' and adding in its place ''areas of Indian country within the borders of the State not subject to the State's SIP authority, the'';

■ u. In paragraph (b)(7) introductory text, removing ''(b)(2)(iii) or (iv)'' and adding in its place ''(b)(2)(ii)'';

■ v. Revising paragraph (b)(8) introductory text;

■ w. In paragraph (b)(8)(i), adding ''and'' after the semicolon;

■ x. Removing and reserving paragraph (b)(8)(ii);

■ y. Revising paragraph (b)(8)(iii)(A);

■ z. In table 5 to paragraph (b)(8)(iii)(B), revising the entry for ''2025 and any year thereafter'';

■ aa. In paragraph (b)(8)(iv), removing ''(b)(8)(i), (ii), or (iii)'' and adding in its place ''(b)(8)(i) or (iii)'' each time it appears;

■ bb. Revising paragraph (b)(9) introductory text;

■ cc. Removing and reserving paragraph (b)(9)(ii);

■ dd. Revising paragraph (b)(9)(iii)(A);

■ ee. In table 6 to paragraph (b)(9)(iii)(B), revising the entry for ''2025 and any year thereafter'';

■ ff. In paragraph (b)(9)(vi), removing ''Indian country within the borders of the State'' and adding in its place ''areas of Indian country within the borders of the State not subject to the State's SIP authority'';

■ gg. Revising paragraph (b)(9)(vii);

■ hh. In paragraph (b)(9)(viii), removing ''(b)(9)(i), (ii), or (iii)'' and adding in its place ''(b)(9)(i) or (iii)'';

■ ii. Revising paragraphs (b)(10) introductory text, (b)(10)(i) and (ii), (b)(10)(v)(A) and (B), (b)(11) introductory text, (b)(11)(iii) introductory text, (b)(11)(iii)(A) introductory text, and (b)(11)(iii)(B);

■ jj. Removing and reserving paragraph (b)(11)(iii)(C);

■ kk. Revising paragraph (b)(11)(iii)(D);

■ ll. In paragraph (b)(11)(iv), removing ''paragraphs (b)(11)(iii)(B) and (C)'' and adding in its place ''paragraph (b)(11)(iii)(B)'';

■ mm. Revising paragraphs (b)(12) introductory text, (b)(12)(iii) introductory text, (b)(12)(iii)(A) introductory text, and (b)(12)(iii)(B);

■ nn. Removing and reserving paragraph (b)(12)(iii)(C);

■ oo. Revising paragraphs (b)(12)(iii)(D) and (b)(12)(vi) and (vii);

■ pp. In paragraph (b)(12)(viii), removing ''paragraphs (b)(12)(iii)(B) and (C)'' and adding in its place ''paragraph (b)(12)(iii)(B)'';

■ qq. Revising paragraphs (b)(13) introductory text and (b)(13)(i);
■ rr. In paragraph (b)(13)(ii), removing ''(b)(9)(ii) or'';
■ ss. In paragraph (b)(14)(i)(F), removing ''§ 97.825(b)'' and adding in its place ''§§ 97.806(c)(2) and (3) and 97.825(b)'';
■ tt. In paragraph (b)(14)(i)(G), removing ''§ 97.826(e)'' and adding in its place ''§ 97.826(f)'';
■ uu. Revising paragraphs (b)(14)(ii) and (b)(14)(iii) introductory text;
■ vv. In paragraph (b)(14)(iii)(D), removing ''and'' after the semicolon;
■ ww. In paragraph (b)(14)(iii)(E), removing ''(b)(2)(iv) of this section).'' and adding in its place ''(b)(2)(ii)(B) of this section);'';
■ xx. Adding paragraphs (b)(14)(iii)(F) and (G);
■ yy. In paragraph (b)(15)(iii), removing ''State (but not sources in any Indian country within the borders of the State):'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority:'';
■ zz. In paragraph (b)(16)(i)(B), removing ''§ 97.804(a) and (b) or'';
■ aaa. Revising paragraph (b)(16)(i)(C);
■ bbb. Redesignating paragraph (b)(16)(ii) as paragraph (b)(16)(ii)(A), and in the newly redesignated paragraph, removing ''(b)(2)(iv)'' and adding in its place ''(b)(2)(ii)(B)'';
■ ccc. Adding paragraph (b)(16)(ii)(B); and
■ ddd. Revising paragraphs (b)(17)(i) through (iii).

The revisions and additions read as follows:

§ 52.38 What are the requirements of the Federal Implementation Plans (FIPs) for the Cross-State Air Pollution Rule (CSAPR) relating to emissions of nitrogen oxides?

(a) * * *

(4) * * *

(i) * * *

(B) * * *

TABLE 1 TO PARAGRAPH (a)(4)(i)(B)

Year of the control period for which CSAPR NO_X annual allowances are allocated or auctioned	Deadline for submission of allocations or auction results to the Administrator
* * * * * * *	
2025 and any year thereafter	June 1 of the year before the year of the control period.

* * * * *

(5) * * *

(i) * * *

(B) * * *

TABLE 2 TO PARAGRAPH (a)(5)(i)(B)

Year of the control period for which CSAPR NO_X annual allowances are allocated or auctioned	Deadline for submission of allocations or auction results to the Administrator
* * * * * * *	
2025 and any year thereafter	June 1 of the year before the year of the control period.

* * * * *

(6) *Withdrawal of CSAPR FIP provisions relating to NO_X annual emissions.* Except as provided in paragraph (a)(7) of this section, following promulgation of an approval by the Administrator of a State's SIP revision as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan set forth in paragraphs (a)(1), (a)(2)(i), and (a)(3) and (4) of this section for sources in the State and Indian country within the borders of the State, the provisions of paragraph (a)(2)(i) of this section will no longer apply to sources in the State and areas of Indian country within the borders of the State subject to the State's SIP authority, unless the Administrator's approval of the SIP revision is partial or conditional, and will continue to apply to sources in areas of Indian country within the borders of the State not subject to the State's SIP authority, provided that if the CSAPR Federal Implementation Plan was promulgated as a partial rather than full remedy for an obligation of the State to address interstate air pollution, the SIP revision likewise will constitute a partial rather than full remedy for the State's obligation unless provided otherwise in the Administrator's approval of the SIP revision.

(7) * * *

(ii) Notwithstanding the provisions of paragraph (a)(6) of this section, if, at the time of any approval of a State's SIP revision under this section, the Administrator has already started recording any allocations of CSAPR NO_X Annual allowances under subpart AAAAA of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of such subpart authorizing the Administrator to complete the allocation and recordation of such allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

* * * * *

(b) * * *

(2) * * *

(ii) * * *

(C) The provisions of subpart EEEEE of part 97 of this chapter apply to sources in each of the following States and Indian country located within the borders of such States with regard to emissions occurring in 2017 through 2022 only, except as provided in paragraph (b)(14)(iii) of this section: Alabama, Arkansas, Mississippi, Missouri, Oklahoma, Tennessee, Texas, and Wisconsin.

(iii) * * *

(B) The provisions of subpart GGGGG of part 97 of this chapter apply to sources in each of the following States and Indian country located within the borders of such States with regard to emissions occurring in 2023 and each subsequent year: Alabama, Arkansas, Mississippi, Missouri, Oklahoma, Tennessee, Texas, and Wisconsin.

(C) The provisions of subpart GGGGG of part 97 of this chapter apply to sources in each of the following States and Indian country located within the borders of such States with regard to emissions occurring on and after [EFFECTIVE DATE OF FINAL RULE] and in each subsequent year: Delaware, Minnesota, Nevada, Utah, and Wyoming.

* * * * *

(4) *Abbreviated SIP revisions replacing certain provisions of the federal CSAPR NO_X Ozone Season Group 1 Trading Program.* A State listed in paragraph (b)(2)(i)(A) of this section may adopt and include in a SIP revision, and the Administrator will approve, regulations replacing specified provisions of subpart BBBBB of part 97 of this chapter for the State, and not substantively replacing any other provisions, as follows:

* * * * *

(ii) * * *

(B) * * *

TABLE 3 TO PARAGRAPH (b)(4)(ii)(B)

Year of the control period for which CSAPR NO_X ozone season Group 1 allowances are allocated or auctioned	Deadline for submission of allocations or auction results to the Administrator
* * *	* * * *
2025 and any year thereafter	June 1 of the year before the year of the control period.

* * * * *

(5) *Full SIP revisions adopting State CSAPR NO_X Ozone Season Group 1 Trading Programs.* A State listed in paragraph (b)(2)(i)(A) of this section may adopt and include in a SIP revision, and the Administrator will approve, as correcting the deficiency in the SIP that is the basis for the CSAPR Federal Implementation Plan set forth in paragraphs (b)(1), (b)(2)(i), and (b)(3) and (4) of this section with regard to sources in the State and areas of Indian country within the borders of the State subject to the State's SIP authority, regulations that are substantively identical to the provisions of the CSAPR NO_X Ozone Season Group 1 Trading Program set forth in §§ 97.502 through 97.535 of this chapter, except that the SIP revision:

* * * * *

(ii) * * *

(B) * * *

Year of the control period for which CSAPR NO_X ozone season Group 1 allowances are allocated or auctioned	Deadline for submission of allocations or auction results to the Administrator
* * *	* * * *
2025 and any year thereafter	June 1 of the year before the year of the control period.

* * * * *

(8) *Abbreviated SIP revisions replacing certain provisions of the federal CSAPR NO_X Ozone Season Group 2 Trading Program.* A State listed in paragraph (b)(2)(ii) of this section may adopt and include in a SIP revision, and the Administrator will approve, regulations replacing specified provisions of subpart EEEEE of part 97 of this chapter for the State, and not substantively replacing any other provisions, as follows:

* * * * *

(iii) * * *

(A) Requires the State or the permitting authority to allocate and, if applicable, auction a total amount of CSAPR NO_X Ozone Season Group 2 allowances for any such control period not exceeding the amount, under §§ 97.810(a) and 97.821 of this chapter for the State and such control period, of the CSAPR NO_X Ozone Season Group 2 trading budget minus the sum of the Indian country new unit set-aside and the amount of any CSAPR NO_X Ozone Season Group 2 allowances already allocated and recorded by the Administrator;

(B) * * *

* * *	* * * *
2025 and any year thereafter	June 1 of the year before the year of the control period.

* * * * *

(9) *Full SIP revisions adopting State CSAPR NO_X Ozone Season Group 2 Trading Programs.* A State listed in paragraph (b)(2)(ii) of this section may adopt and include in a SIP revision, and the Administrator will approve, as correcting the deficiency in the SIP that is the basis for the CSAPR Federal Implementation Plan set forth in paragraphs (b)(1), (b)(2)(ii), and (b)(7) and (8) of this section with regard to sources in the State and areas of Indian country within the borders of the State subject to the State's SIP authority, regulations that are substantively identical to the provisions of the CSAPR NO_X Ozone Season Group 2 Trading Program set forth in §§ 97.802 through 97.835 of this chapter, except that the SIP revision:

* * * * *

(iii) * * *

(A) Requires the State or the permitting authority to allocate and, if applicable, auction a total amount of CSAPR NO_X Ozone Season Group 2 allowances for any such control period not exceeding the amount, under

§§ 97.810(a) and 97.821 of this chapter for the State and such control period, of the CSAPR NO_X Ozone Season Group 2 trading budget minus the sum of the Indian country new unit set-aside and the amount of any CSAPR NO_X Ozone Season Group 2 allowances already allocated and recorded by the Administrator;

(B) * * *

TABLE 6 TO PARAGRAPH (b)(9)(iii)(B)

Year of the control period for which CSAPR NO_X ozone season Group 2 allowances are allocated or auctioned	Deadline for submission of allocations or auction results to the Administrator
* * *	* * * *
2025 and any year thereafter	June 1 of the year before the year of the control period.

* * * * *

(vii) Provided that, if and when any covered unit is located in areas of Indian country within the borders of the State not subject to the State's SIP authority, the Administrator may modify his or her approval of the SIP revision to exclude the provisions in §§ 97.802 (definitions of ''common designated representative'', ''common designated representative's assurance level'', and ''common designated representative's share''), 97.806(c)(2), and 97.825 of this chapter and the portions of other provisions of subpart EEEEE of part 97 of this chapter referencing these sections and may modify any portion of the CSAPR Federal Implementation Plan that is not replaced by the SIP revision to include these provisions; and

* * * * *

(10) *State-determined allocations of CSAPR NO_X Ozone Season Group 3 allowances for 2024.* A State listed in paragraph (b)(2)(iii) of this section may adopt and include in a SIP revision, and the Administrator will approve, as CSAPR NO_X Ozone Season Group 3 allowance allocation provisions replacing the provisions in § 97.1011(a)(1) of this chapter with regard to the State and the control period in 2024, a list of CSAPR NO_X Ozone Season Group 3 units and the amount of CSAPR NO_X Ozone Season Group 3 allowances allocated to each unit on such list, provided that the list of units and allocations meets the following requirements:

(i) All of the units on the list must be units that are in the State and areas of Indian country within the borders of the State subject to the State's SIP authority and that commenced commercial operation before January 1, 2021;

(ii) The total amount of CSAPR NO_X Ozone Season Group 3 allowance allocations on the list must not exceed the amount, under § 97.1010 of this chapter for the State and the control period in 2024, of the CSAPR NO_X Ozone Season Group 3 trading budget minus the sum of the new unit set-aside and Indian country existing unit set-aside;

* * * * *

(v) * * *

(A) By [EFFECTIVE DATE OF FINAL RULE], the State must notify the Administrator electronically in a format specified by the Administrator of the State's intent to submit to the Administrator a complete SIP revision meeting the requirements of paragraphs (b)(10)(i) through (iv) of this section by September 1, 2023; and

(B) The State must submit to the Administrator a complete SIP revision described in paragraph (b)(10)(v)(A) of this section by September 1, 2023.

(11) *Abbreviated SIP revisions replacing certain provisions of the federal CSAPR NO_X Ozone Season Group 3 Trading Program.* A State listed in paragraph (b)(2)(iii) of this section may adopt and include in a SIP revision, and the Administrator will approve, regulations replacing specified provisions of subpart GGGGG of part 97 of this chapter for the State, and not substantively replacing any other provisions, as follows:

* * * * *

(iii) The State may adopt, as CSAPR NO_X Ozone Season Group 3 allowance allocation or auction provisions replacing the provisions in § 97.1011(a)(1) of this chapter with regard to the State and the control period in 2025 or any subsequent year, any methodology under which the State or the permitting authority allocates or auctions CSAPR NO_X Ozone Season Group 3 allowances and may adopt, in addition to the definitions in § 97.1002 of this chapter, one or more definitions that shall apply only to terms as used in the adopted CSAPR NO_X Ozone Season Group 3 allowance allocation or auction provisions, if such methodology—

(A) Requires the State or the permitting authority to allocate and, if applicable, auction a total amount of CSAPR NO_X Ozone Season Group 3 allowances for any such control period not exceeding the amount, under §§ 97.1010 and 97.1021 of this chapter for the State and such control period, of the CSAPR NO_X Ozone Season Group 3 trading budget minus the sum of the new unit set-aside, the Indian country existing unit set-aside, and the amount of any CSAPR NO_X Ozone Season Group 3 allowances already allocated and recorded by the Administrator, plus, if the State adopts regulations expanding applicability to additional units pursuant to paragraph (b)(11)(ii) of this section, an additional amount of CSAPR NO_X Ozone Season Group 3 allowances not exceeding the lesser of:

* * * * *

(B) Requires, to the extent the State adopts provisions for allocations or auctions of CSAPR NO_X Ozone Season Group 3 allowances for any such control period to any CSAPR NO_X Ozone Season Group 3 units covered by § 97.1011(a)(1) of this chapter, that the State or the permitting authority submit such allocations or the results of such auctions for such control period (except allocations or results of auctions to such units of CSAPR NO_X Ozone Season Group 3 allowances remaining in a set-aside after completion of the allocations or auctions for which the set-aside was created) to the Administrator by June 1 of the year before the year of such control period; and

* * * * *

(D) Does not provide for any change, after the submission deadlines in paragraph (b)(11)(iii)(B) of this section, in the allocations submitted to the Administrator by such deadlines and does not provide for any change in any allocation determined and recorded by the Administrator under subpart GGGGG of part 97 of this chapter or § 97.526(d) or § 97.826(d) or (e) of this chapter;

* * * * *

(12) *Full SIP revisions adopting State CSAPR NO_X Ozone Season Group 3 Trading Programs.* A State listed in paragraph (b)(2)(iii) of this section may adopt and include in a SIP revision, and the Administrator will approve, as correcting the deficiency in the SIP that is the basis for the CSAPR Federal

Implementation Plan set forth in paragraphs (b)(1), (b)(2)(iii), and (b)(10) and (11) of this section with regard to sources in the State and areas of Indian country within the borders of the State subject to the State's SIP authority, regulations that are substantively identical to the provisions of the CSAPR NO_X Ozone Season Group 3 Trading Program set forth in §§ 97.1002 through 97.1035 of this chapter, except that the SIP revision:

* * * * *

(iii) May adopt, as CSAPR NO_X Ozone Season Group 3 allowance allocation provisions replacing the provisions in § 97.1011(a)(1) of this chapter with regard to the State and the control period in 2025 or any subsequent year, any methodology under which the State or the permitting authority allocates or auctions CSAPR NO_X Ozone Season Group 3 allowances and that—

(A) Requires the State or the permitting authority to allocate and, if applicable, auction a total amount of CSAPR NO_X Ozone Season Group 3 allowances for any such control period not exceeding the amount, under §§ 97.1010 and 97.1021 of this chapter for the State and such control period, of the CSAPR NO_X Ozone Season Group 3 trading budget minus the sum of the new unit set-aside, the Indian country existing unit set-aside, and the amount of any CSAPR NO_X Ozone Season Group 3 allowances already allocated and recorded by the Administrator, plus, if the State adopts regulations expanding applicability to additional units pursuant to paragraph (b)(12)(ii) of this section, an additional amount of CSAPR NO_X Ozone Season Group 3 allowances not exceeding the lesser of:

* * * * *

(B) Requires, to the extent the State adopts provisions for allocations or auctions of CSAPR NO_X Ozone Season Group 3 allowances for any such control period to any CSAPR NO_X Ozone Season Group 3 units covered by § 97.1011(a)(1) of this chapter, that the State or the permitting authority submit such allocations or the results of such auctions for such control period (except allocations or results of auctions to such units of CSAPR NO_X Ozone Season Group 3 allowances remaining in a set-aside after completion of the allocations or auctions for which the set-aside was created) to the Administrator by June 1 of the year before the year of such control period; and

* * * * *

(D) Does not provide for any change, after the submission deadlines in paragraph (b)(12)(iii)(B) of this section, in the allocations submitted to the Administrator by such deadlines and does not provide for any change in any allocation determined and recorded by the Administrator under subpart GGGGG of part 97 of this chapter or § 97.526(d) or § 97.826(d) or (e) of this chapter;

* * * * *

(vi) Must not include any of the requirements imposed on any unit in areas of Indian country within the borders of the State not subject to the State's SIP authority in the provisions in §§ 97.1002 through 97.1035 of this chapter and must not include the provisions in §§ 97.1011(a)(2), 97.1012, and 97.1021(g) through (j) of this chapter, all of which provisions will continue to apply under the portion of the CSAPR Federal Implementation Plan that is not replaced by the SIP revision;

(vii) Provided that, if any covered unit is located in areas of Indian country within the borders of the State not subject to the State's SIP authority before the Administrator's approval of the SIP revision, the SIP revision must exclude the provisions in §§ 97.1002 (definitions of ''base CSAPR NO_X Ozone Season Group 3 source'', ''base CSAPR NO_X Ozone Season Group 3 unit'', ''common designated representative'', ''common designated representative's assurance level'', and ''common designated representative's share''), 97.1006(c)(2), and 97.1025 of this chapter and the portions of other provisions of subpart GGGGG of part 97 of this chapter referencing these sections, and further provided that, if and when any covered unit is located in areas of Indian country within the borders of the State not subject to the State's SIP authority after the Administrator's approval of the SIP revision, the Administrator may modify his or her approval of the SIP revision to exclude these provisions and may modify any portion of the CSAPR Federal Implementation Plan that is not replaced by the SIP revision to include these provisions; and

* * * * *

(13) *Withdrawal of CSAPR FIP provisions relating to NO_X ozone season emissions; satisfaction of NO_X SIP Call requirements.* Following promulgation of an approval by the Administrator of a State's SIP revision as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan set forth in paragraphs (b)(1), (b)(2)(i), and (b)(3) and (4) of this section, paragraphs (b)(1), (b)(2)(ii), and (b)(7) and (8) of this section, or paragraphs (b)(1), (b)(2)(iii), and (b)(10) and (11) of this section for sources in the State and areas of Indian country within the borders of the State subject to the State's SIP authority—

(i) Except as provided in paragraph (b)(14) of this section, the provisions of paragraph (b)(2)(i), (ii), or (iii) of this section, as applicable, will no longer apply to sources in the State and areas of Indian country within the borders of the State subject to the State's SIP authority, unless the Administrator's approval of the SIP revision is partial or conditional, and will continue to apply to sources in areas of Indian country within the borders of the State not subject to the State's SIP authority, provided that if the CSAPR Federal Implementation Plan was promulgated as a partial rather than full remedy for an obligation of the State to address interstate air pollution, the SIP revision likewise will constitute a partial rather than full remedy for the State's obligation unless provided otherwise in the Administrator's approval of the SIP revision; and

* * * * *

(14) * * *

(ii) Notwithstanding the provisions of paragraph (b)(13)(i) of this section, if, at the time of any approval of a State's SIP revision under this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 1 allowances under subpart BBBBB of part 97 of this chapter, or allocations of CSAPR NO_X Ozone Season Group 2 allowances under subpart EEEEE of part 97 of this chapter, or allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter, to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of such subpart authorizing the Administrator to complete the allocation and recordation of such allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(iii) Notwithstanding any discontinuation of the applicability of subpart BBBBB or EEEEE of part 97 of this chapter to the sources in a State and areas of Indian country within the borders of the State subject to the State's SIP authority with regard to emissions occurring in any control period pursuant to paragraph (b)(2)(i)(B), (b)(2)(ii)(B) or (C), or (b)(13)(i) of this section, the following provisions shall continue to apply with regard to all CSAPR NO_X Ozone Season Group 1 allowances and CSAPR NO_X Ozone Season Group 2 allowances at any time allocated for any control period to any source or other entity in the State and shall apply to all entities, wherever located, that at any time held or hold such allowances:

* * * * *

(F) The provisions of § 97.826(e) of this chapter (concerning the conversion of amounts of unused CSAPR NO_X Ozone Season Group 2 allowances allocated for control periods before 2023 to different amounts of CSAPR NO_X Ozone Season Group 3 allowances); and

(G) The provisions of § 97.811(e) of this chapter (concerning the recall of CSAPR NO_X Ozone Season Group 2 allowances equivalent in quantity and usability to all CSAPR NO_X Ozone Season Group 2 allowances allocated for control periods after 2022 and recorded in the compliance accounts of sources in States listed in paragraph (b)(2)(ii)(C) of this section).

* * * * *

(16) * * *

(i) * * *

(C) For each of the following States, the Administrator has approved a SIP revision under paragraph (b)(9) of this section as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan set forth in paragraphs (b)(1), (b)(2)(ii), and (b)(7) and (8) of this section with regard to sources in the State and areas of Indian country within the borders of the State subject to the State's SIP authority: Alabama, Indiana, and Missouri.

(ii) * * *

(B) Notwithstanding any provision of subpart EEEEE of part 97 of this chapter or any State's SIP, with regard to any State listed in paragraph (b)(2)(ii)(C) of this section and any control period that begins after December 31, 2022, the Administrator will not carry out any of the functions set forth for the Administrator in subpart EEEEE of part 97 of this chapter, except §§ 97.811(e) and 97.826(c) and (e) of this chapter, or in any emissions trading program provisions in a State's SIP approved under paragraph (b)(8) or (9) of this section.

(17) * * *

(i) For each of the following States, the Administrator has approved a SIP revision under paragraph (b)(10) of this section as replacing the CSAPR NO_X Ozone Season Group 3 allowance allocation provisions in § 97.1011(a)(1) of this chapter with regard to the State and the control period in 2024: [none].

(ii) For each of the following States, the Administrator has approved a SIP revision under paragraph (b)(11) of this section as replacing the CSAPR NO_X Ozone Season Group 3 applicability provisions in § 97.1004(a) and (b) or § 97.1004(a)(1) and (2) of this chapter or the CSAPR NO_X Ozone Season Group 2 allowance allocation provisions in § 97.1011(a)(1) of this chapter with regard to the State and the control period in 2025 or any subsequent year: [none].

(iii) For each of the following States, the Administrator has approved a SIP revision under paragraph (b)(12) of this section as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan set forth in paragraphs (b)(1), (b)(2)(iii), and (b)(10) and (11) of this section with regard to sources in the State and areas of Indian country within the borders of the State subject to the State's SIP authority: [none].

■ 3. Amend § 52.39 by:

■ a. In paragraph (a), removing "(SO_2), except" and adding in its place "(SO_2) for sources meeting the applicability criteria set forth in those subparts, except";

■ b. In paragraph (e) introductory text, removing "State's sources, and" and adding in its place "State, and";

■ c. In table 1 to paragraph (e)(1)(ii), revising the entry for "2025 and any year thereafter";

■ d. In paragraph (f) introductory text, removing "State (but not sources in any Indian country within the borders of the State), regulations" and adding in its place "State and areas of Indian country within the borders of the State subject to the State's SIP authority, regulations";

■ e. In table 2 to paragraph (f)(1)(ii), revising the entry for "2025 and any year thereafter";

■ f. In paragraph (f)(4), removing "Indian country within the borders of the State" and adding in its place "areas of Indian country within the borders of the State not subject to the State's SIP authority";

■ g. In paragraph (f)(5), removing "Indian country within the borders of the State, the" and adding in its place "areas of Indian country within the borders of the State not subject to the State's SIP authority, the";

■ h. In paragraph (h) introductory text, removing "State's sources, and" and adding in its place "State, and";

■ i. In table 3 to paragraph (h)(1)(ii), revising the entry for "2025 and any year thereafter";

■ j. In paragraph (i) introductory text, removing "State (but not sources in any Indian country within the borders of the State), regulations" and adding in its place "State and areas of Indian country within the borders of the State subject to the State's SIP authority, regulations";

■ k. In table 4 to paragraph (i)(1)(ii), revising the entry for "2025 and any year thereafter";

■ l. In paragraph (i)(4), removing "Indian country within the borders of the State" and adding in its place "areas of Indian country within the borders of the State not subject to the State's SIP authority";

■ m. In paragraph (i)(5), removing "Indian country within the borders of the State, the" and adding in its place "areas of Indian country within the borders of the State not subject to the State's SIP authority, the";

■ n. Revising paragraphs (j) and (k)(2); and

■ o. In paragraphs (l)(3) and (m)(3), removing "State (but not sources in any Indian country within the borders of the State):" and adding in its place "State and areas of Indian country within the borders of the State subject to the State's SIP authority:".

The revisions read as follows:

§ 52.39 What are the requirements of the Federal Implementation Plans (FIPs) for the Cross-State Air Pollution Rule (CSAPR) relating to emissions of sulfur dioxide?

(j) *Withdrawal of CSAPR FIP provisions relating to SO_2 emissions.* Except as provided in paragraph (k) of this section, following promulgation of an approval by the Administrator of a State's SIP revision as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan set forth in paragraphs (a), (b), (d), and (e) of this section or paragraphs (a), (c)(1), (g), and (h) of this section for sources in the State and Indian country within the borders of the State, the provisions of paragraph (b) or (c)(1) of this section, as applicable, will no longer apply to sources in the State and areas of Indian country within the borders of the State subject to the State's SIP authority, unless the Administrator's approval of the SIP revision is partial or conditional, and will continue to apply to sources in areas of Indian country within the borders of the State not subject to the State's SIP authority, provided that if the CSAPR Federal Implementation Plan was promulgated as a partial rather than full remedy for an obligation of the State to address interstate air pollution, the SIP revision likewise will constitute a partial rather than full remedy for the State's obligation unless provided otherwise in the Administrator's approval of the SIP revision.

(k) * * *

(2) Notwithstanding the provisions of paragraph (j) of this section, if, at the time of any approval of a State's SIP revision under this section, the Administrator has already started recording any allocations of CSAPR SO_2 Group 1 allowances under subpart CCCCC of part 97 of this chapter, or allocations of CSAPR SO_2 Group 2 allowances under subpart DDDDD of part 97 of this chapter, to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of such subpart authorizing the Administrator to complete the allocation and recordation of such allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

* * * * *

■ 4. Add §§ 52.40 through 52.45 to read as follows:

* * * * *

Sec.

* * * * *

§ 52.40 What are the requirements of the Federal Implementation Plans (FIPs) relating to ozone season emissions of nitrogen oxides from sources not subject to the CSAPR ozone season trading program?

(a) *NO_X ozone season emissions.* This section establishes Federal Implementation Plan requirements for new and existing units in the industries specified in paragraph (b) of this section to eliminate significant contribution to nonattainment, or interference with maintenance, of the 2015 8-hour ozone National Ambient Air Quality Standards in other states pursuant to 42 U.S.C. 7410(a)(2)(D)(i)(I).

(b) *General requirements* (1) The NO_X emissions limitations and associated compliance requirements for the following listed source categories not subject to the CSAPR ozone season trading program constitute the Federal Implementation Plan provisions that relate to emissions of NO_X during the ozone season (defined as May 1 through September 30 of a calendar year): § 52.41 for engines in the Pipeline Transportation of Natural Gas Industry, § 52.42 for kilns in the Cement and Concrete Product Manufacturing Industry, § 52.43 for units in the Iron and Steel Mills and Ferroalloy Manufacturing Industry, § 52.44 for units in the Glass and Glass Product Manufacturing Industry, § 52.45 for boilers in Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mills.

(2) The provisions of §§ 52.41 through 52.45 of this part apply to sources located in each of the following States, including Indian country located within the borders of such States, beginning in the 2026 ozone season and in each subsequent ozone season: Arkansas, California, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming.

(3) The owner or operator of an affected unit subject to the provisions of §§ 52.40 through 52.45 shall maintain files of all information (including all reports and notifications) required by these sections recorded in a form suitable and readily available for expeditious inspection and review. The files shall be retained for at least 5 years following the date of each occurrence, measurement, maintenance, corrective action, report, or record. At a minimum, the most recent 2 years of data shall be retained on site. The remaining 3 years of data may be retained off site. Such files may be maintained on microfilm, on a computer, on computer floppy disks, on magnetic tape disks, or on microfiche.

§ 52.41 What are the requirements of the Federal Implementation Plans (FIPs) relating to ozone season emissions of nitrogen oxides from the Pipeline Transportation of Natural Gas Industry?

(a) *Definitions.* All terms not defined herein shall have the meaning given them in the Act and in subpart A of part 60.

Affected unit means an engine meeting the applicability criteria of this section.

Four stroke means any type of engine which completes the power cycle in two crankshaft revolutions, with intake and compression strokes in the first revolution and power and exhaust strokes in the second revolution.

ISO conditions means 288 Kelvin (15 °C), 60 percent relative humidity and 101.3 kilopascals pressure.

Lean burn means any two-stroke or four-stroke spark ignited reciprocating internal combustion engine that does not meet the definition of a rich burn engine.

Nameplate rating means the manufacturer's design maximum capacity in horsepower (hp) at the installation site conditions. Starting from the completion of any physical change in the engine resulting in an increase in the maximum output (in hp) that the engine is capable of producing on a steady state basis and during continuous operation, such increased maximum output shall be as specified by the person conducting the physical change.

Natural gas means a fluid mixture of hydrocarbons (*e.g.,* methane, ethane, or propane) or non-hydrocarbons, composed of at least 70 percent methane by volume or that has a gross calorific value between 35 and 41 megajoules (MJ) per dry standard cubic meter (950 and 1,100 Btu per dry standard cubic foot), that maintains a gaseous state under ISO conditions. Natural gas does not include the following gaseous fuels: Landfill gas, digester gas, refinery gas, sour gas, blast furnace gas, coal-derived gas, producer gas, coke oven gas, or any gaseous fuel produced in a process which might result in highly variable CO_2 content or heating value.

Natural gas-fired means that greater than or equal to 90% of the engine's heat input, excluding recirculated or recuperated exhaust heat, is derived from the combustion of natural gas.

Operator means any person who operates, controls, or supervises a natural gas-fired engine subject to this regulation and shall include, but not be limited to, any holding company, utility system, or plant manager of such natural gas-fired engine.

Owner means any holder of any portion of the legal or equitable title in a natural gas-fired engine subject to this regulation.

Pipeline transportation of natural gas means the movement of natural gas through an interconnected network of compressors and pipeline components, from field gathering networks near wellheads to end users, including:

(i) The compressor and pipeline network used for field gathering of natural gas from the wellheads for delivery to either processing facilities or connections to pipelines used for intrastate or interstate transportation of the natural gas; and

(ii) The compressor and pipeline network used to transport the natural gas from field gathering networks or processing facilities over a distance (intrastate or interstate) to and from storage facilities, to large natural gas end-users, and to distribution organizations that provide the natural gas to end-users.

Reciprocating internal combustion engine means a reciprocating engine in which power, produced by heat and/or pressure that is developed in the engine combustion chambers by the burning of a mixture of air and fuel, is subsequently converted to mechanical work.

Rich burn means any four-stroke spark ignited reciprocating internal combustion engine where the manufacturer's recommended operating air/fuel ratio divided by the stoichiometric air/fuel ratio at full load conditions is less than or equal to 1.1. Internal combustion engines originally manufactured as rich burn engines but modified with passive emission control technology for nitrogen oxides (NO_X) (such as pre-combustion chambers) will be considered lean burn engines. Existing internal combustion engines where there are no manufacturer's recommendations regarding air/fuel ratio will be considered rich burn engines if the excess oxygen content of the exhaust at full load conditions is less than or equal to 2 percent.

Spark ignition means a reciprocating internal combustion engine utilizing a spark plug (or other sparking device) to ignite the air/fuel mixture and with operating characteristics significantly similar to the theoretical Otto combustion cycle.

Stoichiometric means the theoretical air-to-fuel ratio required for complete combustion.

Two stroke means a type of reciprocating internal combustion engine which completes the power cycle in a single crankshaft revolution by combining the intake and compression operations into one stroke (one-half revolution) and the power and exhaust operations into a second stroke. This system requires auxiliary exhaust scavenging of the combustion products and inherently runs lean (excess of air) of stoichiometry.

(b) *Applicability.* You are subject to the requirements under this section if you own or operate a new or existing natural gas-fired spark ignition engine with a nameplate rating of 1,000 hp or greater that is used for pipeline transportation of natural gas and is located within any of the States listed in § 52.40(a)(1)(ii), including Indian country located within the borders of any such State(s).

(c) *Emissions limitations.* Beginning with the 2026 ozone season and in each ozone season thereafter, the following emissions limitations must be met. Compliance with the numerical emissions limitations established in this section is based on the average of three 1-hour runs using the testing requirements and procedures in paragraph (d) of this section.

(1) If you own or operate a natural gas fired four stroke rich burn spark ignition engine with a nameplate rating of 1,000 hp or greater than you must meet a nitrogen oxides (NO_X) emissions limits of 1.0 grams per hp-hour (g/hp-hr).

(2) If you own or operate a natural gas fired four stroke lean burn spark ignition engine with a nameplate rating of 1,000 hp or greater than you must meet a NO_X emissions limits of 1.5 g/hp-hr.

(3) If you own or operate a natural gas fired two stroke lean spark ignition engine with a nameplate rating of 1,000 hp or greater than you must meet a NO_X emissions limits of 3.0 g/hp-hr.

(d) *Testing and monitoring requirements* (1) If you are an owner or operator of a natural gas fired spark ignition engine subject to a NO_X emissions limit under paragraph (b) of this section, you must keep a maintenance plan and records of conducted maintenance and must, to the extent practicable, maintain and operate the engine in a manner consistent with good air pollution control practice for minimizing emissions.

(2) Performance Testing Requirements:

(i) Engines that meet the certification requirements of § 60.4243(a) need not conduct any performance tests, consistent with the requirements of 40 CFR part 60, subpart JJJJ.

(ii) For non-certified engines, the following performance testing requirements apply:

(A) New engines must conduct an initial performance test within six months of engine startup and conduct subsequent performance testing every six months thereafter to demonstrate compliance.

(B) Existing engines must conduct an initial performance test within six months of becoming subject to an emissions limit under paragraph (b) of this section and conduct subsequent performance testing every six months thereafter to demonstrate compliance.

(iii) Performance tests must be conducted in accordance with the applicable reference test methods of 40 CFR part 60, appendix A, any alternative test method approved by EPA as of April 6, 2022 under 40 CFR 59.104(f), 60.8(b)(3), 61.13(h)(1)(ii), 63.7(e)(2)(ii), or 65.158(a)(2) and available at EPA's website (*https://www.epa.gov/emc/broadly-applicable-approved-alternative-test-methods*), or other methods and procedures approved by EPA through notice-and-comment rulemaking.

(3) If a selective catalytic reduction (SCR) or non-selective catalytic reduction (NSCR) control device is used to reduce emissions:

(i) Monitor the inlet temperature to the catalyst daily and conduct maintenance if the temperature is not within the observed inlet temperature range from the most recent performance test or the temperatures specified by the manufacturer if no performance test was required by this section.

(ii) Measure the pressure drop across the catalyst monthly and conduct maintenance if the pressure drop is greater than 2 inches outside the baseline value established after each semiannual portable analyzer monitoring.

(iii) Engines that are subject to catalyst temperatures and catalyst pressure drop monitoring requirements under 40 CFR part 63, subpart ZZZZ must satisfy the requirements of § 52.41(d)(3).

(4) If you are not using a SCR or NSCR control device to reduce emissions are required to install a continuous parameter monitoring system (CPMS). You must install, operate, and maintain each CPMS according to the requirements in paragraphs (d)(4)(i) through (vi) of this section.

(i) You must prepare a site-specific monitoring plan that addresses the monitoring system design, data collection, and quality assurance and quality control elements outlined in paragraphs (d)(4)(i)(A) through (E) of this section.

(A) The performance criteria and design specifications for the monitoring system equipment, including the sample interface, detector signal analyzer, and data acquisition and calculations.

(B) Sampling interface (*e.g.,* thermocouple) location such that the monitoring system will provide representative measurements.

(C) Equipment performance evaluations, system accuracy audits, or other audit procedures.

(D) Ongoing operation and maintenance procedures in accordance with the requirements of paragraph (d)(1) of this section.

(E) Ongoing recordkeeping and reporting procedures in accordance with the requirements of paragraphs (e) and (f) of this section.

(ii) Install, operate, and maintain each CPMS in continuous operation according to the procedures in your site-specific monitoring plan.

(iii) The CPMS must collect data at least once every 15 minutes.

(iv) For a CPMS for measuring temperature range, the temperature sensor must have a minimum tolerance of 2.8 degrees Celsius (5 degrees Fahrenheit) or 1 percent of the measurement range, whichever is larger.

(v) You must conduct the CPMS equipment performance evaluation, system accuracy audits, or other audit procedures specified in your site-specific monitoring plan at least annually.

(vi) You must conduct a performance evaluation of each CPMS in accordance with your site-specific monitoring plan.

(e) *Recordkeeping requirements* (1) You must keep records of:

(i) Performance tests conducted pursuant to § 52.41(d)(2), including the date, engine settings on the date of the test, and documentation of the methods and results of the testing.

(ii) Catalyst monitoring required by § 52.41(d)(3), if applicable, and any actions taken to address monitored values outside the temperature or pressure drop parameters, including the date and a description of actions taken.

(iii) Parameters monitored pursuant to your site-specific monitoring plan for your CPMS.

(iv) Hours of operation on a daily basis.

(v) Tuning, adjustments, or other combustion process adjustments and the date of the adjustment(s).

(2) Any records required to be maintained by this section that are submitted electronically via the EPA's Compliance and Emissions Data Reporting Interface (CEDRI) may be maintained in electronic format. This ability to maintain electronic copies does not affect the requirement for facilities to make records, data, and reports available upon request to the EPA as part of an on-site compliance evaluation.

(f) *Reporting requirements* (1) Within 60 days after the date of completing each performance test required by this section, you must submit the results of the performance test following the procedures specified in paragraphs (f)(1)(i) through (iii):

(i) *Data collected using test methods supported by the EPA's Electronic Reporting Tool (ERT) as listed on the EPA's ERT website (https://www.epa.gov/electronic-reporting-air-emissions/electronic-reporting-tool-ert) at the time of the test.* Submit the results of the performance test to the EPA via the CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section, which can be accessed through the EPA's Central Data Exchange (CDX) (*https://cdx.epa.gov/*). The data must be submitted in a file format generated using the EPA's ERT. Alternatively, you may submit an electronic file consistent with the extensible markup language (XML) schema listed on the EPA's ERT website.

(ii) *Data collected using test methods that are not supported by the EPA's ERT as listed on the EPA's ERT website at the time of the test.* The results of the performance test must be included as an attachment in the ERT or an alternate electronic file consistent with the XML schema listed on the EPA's ERT website. Submit the ERT generated package or alternative file to the EPA via CEDRI.

(iii) *Confidential business information (CBI). Do not use CEDRI to submit information you claim as CBI.* Anything submitted using CEDRI cannot later be claimed CBI. Although we do not expect persons to assert a claim of CBI, if you wish to assert a CBI claim for some of the information submitted under paragraphs (f)(1)(i) or (ii) of this section, you must submit a complete file, including information claimed to be CBI, to the EPA. The file must be generated using the EPA's ERT or an alternate electronic file consistent with the XML schema listed on the EPA's ERT website. Submit the file on a compact disc, flash drive, or other commonly used electronic storage medium and clearly mark the medium as CBI. Mail the electronic medium to U.S. EPA/OAQPS/CORE CBI Office, MD C404–02, 4930 Old Page Rd., Durham, NC 27703. The same file with the CBI omitted must be submitted to the EPA via the EPA's CDX as described in paragraphs (f)(1)(i) and (ii). All CBI claims must be asserted at the time of submission. Furthermore, under CAA section 114(c), emissions data is not entitled to confidential treatment, and the EPA is required to make emissions data available to the public. Thus, emissions data will not be protected as CBI and will be made publicly available.

(2) If you are the owner or operator of an affected engine, you shall submit a semi-annual report, at least every six months, in PDF format to the EPA via CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section. The report shall contain the following information:

(i) The name and address of the owner and operator;

(ii) The address of the subject engine;

(iii) Longitude and latitude coordinates of the subject engine;

(iv) Identification of the subject engine;

(v) Statement of compliance with the applicable emission limit under § 52.41(b);

(vi) Statement of compliance regarding the conduct of maintenance and operations in a manner consistent with good air pollution control practices for minimizing emissions;

(vii) The date and results of the performance test conducted pursuant to § 52.41(d);

(viii) If applicable, a statement documenting any change in the operating characteristics of the subject engine; and

(ix) A statement certifying that the information included in the semi-annual report is complete and accurate.

(3) If you are required to electronically submit a report through CEDRI in the EPA's CDX, you may assert a claim of EPA system outage for failure to timely comply with that reporting requirement. To assert a claim of EPA system outage, you must meet the requirements outlined in paragraphs (f)(3)(i) through (vii) of this section.

(i) You must have been or will be precluded from accessing CEDRI and submitting a required report within the time prescribed due to an outage of either the EPA's CEDRI or CDX systems.

(ii) The outage must have occurred within the period of time beginning five business days prior to the date that the submission is due.

(iii) The outage may be planned or unplanned.

(iv) You must submit notification to the Administrator in writing as soon as possible following the date you first knew, or through due diligence should have known, that the event may cause or has caused a delay in reporting.

(v) You must provide to the Administrator a written description identifying:

(A) The date(s) and time(s) when CDX or CEDRI was accessed and the system was unavailable;

(B) A rationale for attributing the delay in reporting beyond the regulatory deadline to EPA system outage;

(C) A description of measures taken or to be taken to minimize the delay in reporting; and

(D) The date by which you propose to report, or if you have already met the reporting requirement at the time of the notification, the date you reported.

(vi) The decision to accept the claim of EPA system outage and allow an extension to the reporting deadline is solely within the discretion of the Administrator.

(vii) In any circumstance, the report must be submitted electronically as soon as possible after the outage is resolved.

(4) If you are required to electronically submit a report through CEDRI in the EPA's CDX, you may assert a claim of force majeure for failure to timely comply with that reporting requirement. To assert a claim of force majeure, you must meet the requirements outlined in paragraphs (f)(4)(i) through (v) of this section.

(i) You may submit a claim if a force majeure event is about to occur, occurs, or has occurred or there are lingering effects from such an event within the period of time beginning five business days prior to the date the submission is due. For the purposes of this section, a force majeure event is defined as an event that will be or has been caused by circumstances beyond the control of the affected facility, its contractors, or any entity controlled by the affected facility that prevents you from complying with the requirement to submit a report electronically within the time period prescribed. Examples of such events are acts of nature (*e.g.,* hurricanes, earthquakes, or floods), acts of war or terrorism, or equipment failure or safety hazard beyond the control of the affected facility (*e.g.,* large scale power outage).

(ii) You must submit notification to the Administrator in writing as soon as possible following the date you first knew, or through due diligence should have known, that the event may cause or has caused a delay in reporting.

(iii) You must provide to the Administrator:

(A) A written description of the force majeure event;

(B) A rationale for attributing the delay in reporting beyond the regulatory deadline to the force majeure event;

(C) A description of measures taken or to be taken to minimize the delay in reporting; and

(D) The date by which you propose to report, or if you have already met the reporting requirement at the time of the notification, the date you reported.

(iv) The decision to accept the claim of force majeure and allow an extension to the reporting deadline is solely within the discretion of the Administrator.

(v) In any circumstance, the reporting must occur as soon as possible after the force majeure event occurs.

§ 52.42 What are the requirements of the Federal Implementation Plans (FIPs) relating to ozone season emissions of nitrogen oxides from the Cement and Concrete Product Manufacturing Industry?

(a) *Definitions.* All terms not defined herein shall have the meaning given them in the Act and in subpart A of part 60.

Affected unit means a cement kiln meeting the applicability criteria of this section.

Cement plant means any facility manufacturing cement by either the wet or dry process.

Clinker means the product of a cement kiln from which finished cement is manufactured by milling and grinding.

Cement kiln means an installation, including any associated pre-heater or pre-calciner devices, that produces clinker by heating limestone and other materials to produce Portland cement.

Operating day means a 24-hour period beginning at 12:00 midnight during which the kiln produces clinker at any time.

Rolling average means the weighted average of all data, meeting QA/QC requirements or otherwise normalized, collected during the applicable averaging period. The period of a rolling average stipulates the frequency of data averaging and reporting. To demonstrate compliance with an operating parameter a 30-day rolling average period requires calculation of a new average value each operating day and shall include the average of all the hourly averages of the specific operating parameter. For demonstration of compliance with an emissions limit based on pollutant concentration, a 30-day rolling average is comprised of the average of all the hourly average concentrations over the previous 30 operating days. For demonstration of compliance with an emissions limit based on lbs-pollutant per production unit, the 30-day rolling average is calculated by summing the hourly mass emissions over the previous 30 operating days, then dividing that sum by the total production during the same period.

(b) *Applicability.* You are subject to the requirements of this section if you own or operate a new or existing cement kiln that emits or has the potential to emit 100 tons per year or more of NO_X and is located within any of the States listed in § 52.40(a)(1)(ii), including Indian country located within the borders of any such State(s).

(c) Emission limitations (1) If you own or operate a cement kiln under paragraph (b) of this section you are subject to the NO_X emissions limits in the following table and the NO_X source cap limit under paragraph (c)(2) of this section, beginning with the 2026 ozone season and in each ozone season thereafter.

TABLE 1 TO PARAGRAPH (c)(1)

Kiln type	Proposed NO_X emissions limit (lb/ton of clinker)
Long Wet	4.0
Long Dry	3.0
Preheater	3.8
Precalciner	2.3
Preheater/Precalciner	2.8

(2) The NO_X source cap limit is calculated in accordance with the following equation:

$$CAP2015\ Ozone\ Transport = \frac{(KW\ x\ NW) + (KD\ x\ ND)}{\left(2000\,\dfrac{pounds}{ton}\ x\ 365\,\dfrac{days}{year}\right)}$$

Where:

CAP2015 Ozone Transport = total allowable NO_X emissions from all cement kilns located at one cement plant, in tons per day, on a 30-operating day rolling average basis;

KD = 1.7 pounds NO_X per ton of clinker for dry preheater-precalciner or precalciner kilns;

KW = 3.4 pounds NO_X per ton of clinker for long wet kilns;

ND = the average annual production in tons of clinker plus one standard deviation for the three most recent calendar years from all dry preheater-precalciner or precalciner kilns located at one cement plant; and

NW = the average annual production in tons of clinker plus one standard deviation for the three most recent calendar years from all long wet kilns located at one cement plant.

(d) *Testing and monitoring requirements* (1) If you own or operate a cement manufacturing plant subject to the NO_X emissions limits under paragraph (c) of this section you must conduct performance tests, on a semi-annual basis, in accordance with the applicable reference test methods of 40 CFR part 60, Appendix A, any alternative test method approved by EPA as of April 6, 2022 under 40 CFR 59.104(f), 60.8(b)(3), 61.13(h)(1)(ii), 63.7(e)(2)(ii), or 65.158(a)(2) and available at EPA's website (*https://www.epa.gov/emc/broadly-applicable-approved-alternative-test-methods*), or other methods and procedures approved by EPA through notice-and-comment rulemaking. You must calculate and record the 30-operating day rolling emission rate of NO_X as the total of all hourly emissions data for a cement kiln in the preceding 30 days, divided by the total tons of clinker produced in that kiln during the same 30-operating day period using Equation 6 of 40 CFR 60.64(c)(1), shown in this equation:

$$E_{30D} = k\left(\frac{\sum_{i=1}^{n} Ci\ Qi}{P}\right)$$

Where:
E_{30D} = 30 kiln operating day average emission rate of NO_X, in lbs/ton of clinker.
Ci = Concentration of NO_X for hour i, in ppm.
Qi = Volumetric flow rate of effluent gas for hour i, where Ci and Qi are on the same basis (either wet or dry), in scf/hr.
P = 30 days of clinker production during the same time period as the NO_X emissions measured, in tons.
k = Conversion factor, 1.194×10^{-7} for NO_X, in lb/scf/ppm.
n = Number of kiln operating hours over 30 kiln operating days.

(e) Recordkeeping requirements (1) If you own or operate a cement manufacturing plant subject to the NO_X emissions limits under paragraph (c) of this section you must retain records of the calculations and measurements as required in paragraph (d) of this section for the 5-year period specified in 52.40(b)(3).

(2) Any records required to be maintained by this section that are submitted electronically via the EPA's CEDRI may be maintained in electronic format. This ability to maintain electronic copies does not affect the requirement for facilities to make records, data, and reports available upon request to the EPA as part of an on-site compliance evaluation.

(f) *Reporting requirements* (1) Within 60 days after the date of completing each performance test required by this section, you must submit the results of the performance test following the procedures specified in paragraphs (f)(1)(i) through (iii) of this section:

(i) *Data collected using test methods supported by the EPA's ERT as listed on the EPA's ERT website (https://www.epa.gov/electronic-reporting-air-emissions/electronic-reporting-tool-ert) at the time of the test.* Submit the results of the performance test to the EPA via the CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section, which can be accessed through the EPA's CDX (*https://cdx.epa.gov/*). The data must be submitted in a file format generated using the EPA's ERT. Alternatively, you may submit an electronic file consistent with the XML schema listed on the EPA's ERT website.

(ii) *Data collected using test methods that are not supported by the EPA's ERT as listed on the EPA's ERT website at the time of the test.* The results of the performance test must be included as an attachment in the ERT or an alternate electronic file consistent with the XML schema listed on the EPA's ERT website. Submit the ERT generated package or alternative file to the EPA via CEDRI.

(iii) *CBI. Do not use CEDRI to submit information you claim as CBI.* Anything submitted using CEDRI cannot later be claimed CBI. Although we do not expect persons to assert a claim of CBI, if you wish to assert a CBI claim for some of the information submitted under paragraph (f)(1)(i) or (ii) of this section, you must submit a complete file, including information claimed to be CBI, to the EPA. The file must be generated using the EPA's ERT or an alternate electronic file consistent with the XML schema listed on the EPA's ERT website. Submit the file on a compact disc, flash drive, or other commonly used electronic storage medium and clearly mark the medium as CBI. Mail the electronic medium to U.S. EPA/OAQPS/CORE CBI Office, MD C404–02, 4930 Old Page Rd., Durham, NC 27703. The same file with the CBI omitted must be submitted to the EPA via the EPA's CDX as described in paragraphs (f)(1)(i) and (ii) of this section. All CBI claims must be asserted at the time of submission. Furthermore, under CAA section 114(c), emissions data is not entitled to confidential treatment, and the EPA is required to make emissions data available to the public. Thus, emissions data will not be protected as CBI and will be made publicly available.

(2) If you are the owner or operator of an affected cement kiln, you shall submit a semi-annual, at least every six months, report in PDF format to the EPA via CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section.

(3) If you are required to electronically submit a report through CEDRI in the EPA's CDX, you may assert a claim of EPA system outage for failure to timely comply with that reporting requirement. To assert a claim of EPA system outage, you must meet the requirements outlined in paragraphs (f)(3)(i) through (vii) of this section.

(i) You must have been or will be precluded from accessing CEDRI and submitting a required report within the time prescribed due to an outage of either the EPA's CEDRI or CDX systems.

(ii) The outage must have occurred within the period of time beginning five business days prior to the date that the submission is due.

(iii) The outage may be planned or unplanned.

(iv) You must submit notification to the Administrator in writing as soon as possible following the date you first knew, or through due diligence should have known, that the event may cause or has caused a delay in reporting.

(v) You must provide to the Administrator a written description identifying:

(A) The date(s) and time(s) when CDX or CEDRI was accessed and the system was unavailable;

(B) A rationale for attributing the delay in reporting beyond the regulatory deadline to EPA system outage;

(C) A description of measures taken or to be taken to minimize the delay in reporting; and

(D) The date by which you propose to report, or if you have already met the reporting requirement at the time of the notification, the date you reported.

(vi) The decision to accept the claim of EPA system outage and allow an extension to the reporting deadline is solely within the discretion of the Administrator.

(vii) In any circumstance, the report must be submitted electronically as soon as possible after the outage is resolved.

(4) If you are required to electronically submit a report through CEDRI in the EPA's CDX, you may assert a claim of force majeure for failure to timely comply with that reporting requirement. To assert a claim of force majeure, you must meet the requirements outlined in paragraphs (f)(4)(i) through (v) of this section.

(i) You may submit a claim if a force majeure event is about to occur, occurs, or has occurred or there are lingering effects from such an event within the period of time beginning five business days prior to the date the submission is due. For the purposes of this section, a force majeure event is defined as an event that will be or has been caused by circumstances beyond the control of the affected facility, its contractors, or any entity controlled by the affected facility that prevents you from complying with the requirement to submit a report electronically within the time period prescribed. Examples of such events are acts of nature (*e.g.,* hurricanes, earthquakes, or floods), acts of war or terrorism, or equipment failure or safety hazard beyond the control of the affected facility (*e.g.,* large scale power outage).

(ii) You must submit notification to the Administrator in writing as soon as possible following the date you first knew, or through due diligence should have known, that the event may cause or has caused a delay in reporting.

(iii) You must provide to the Administrator:

(A) A written description of the force majeure event;

(B) A rationale for attributing the delay in reporting beyond the regulatory deadline to the force majeure event;

(C) A description of measures taken or to be taken to minimize the delay in reporting; and

(D) The date by which you propose to report, or if you have already met the reporting requirement at the time of the notification, the date you reported.

(iv) The decision to accept the claim of force majeure and allow an extension to the reporting deadline is solely within the discretion of the Administrator.

(v) In any circumstance, the reporting must occur as soon as possible after the force majeure event occurs.

§ 52.43 What are the requirements of the Federal Implementation Plans (FIPs) relating to ozone season emissions of nitrogen oxides from the Iron and Steel Mills and Ferroalloy Manufacturing Industry?

(a) *Definitions.* All terms not defined herein shall have the meaning given them in the Act and in subpart A of part 60.

Affected unit means any annealing furnace, basic oxygen process furnace, blast furnace, coke oven facility, electric arc furnace, ladle metallurgy furnace, ladle/tundish preheating system, reheat furnace, taconite production kiln, vacuum degasser, and industrial boiler meeting the applicability criteria of this section, and any such unit contained within a BOF Shop meeting the applicability criteria of this section.

Annealing furnace shall mean a furnace used to heat materials at very high temperatures to change their hardness and strength properties.

Basic Oxygen Process Furnace (BOF) shall mean a refractory-lined vessel in which high-purity oxygen is blown under pressure through a bath of molten iron, scrap metal, and fluxes to produce steel. This definition includes both top and bottom blown furnaces, but does not include argon oxygen decarburization furnaces.

Blast furnace means refractory-lined furnaces charged through its top with iron ore pellets (taconite), sinter, flux (limestone and dolomite), and coke in a reducing atmosphere to produce iron.

BOF Shop means the place where steel making operations occur, beginning with the transfer of molten iron (hot metal) from the torpedo car and ending just prior to casting the molten steel, including hot metal transfer, desulfurization, slag skimming, refining in a basic oxygen process furnace, and ladle metallurgy.

BOF Baghouse System means the control system for control of emissions from charging and tapping of the BOFs, including the capture hoods, ductwork and the BOF Baghouse.

Coke means carbon product that is formed by the thermal distillation of coal at high temperatures in the absence of air in coke oven batteries.

Coke Ovens means ovens producing coke for use in blast furnaces.

Day means a calendar day unless expressly stated to be a business day. In computing any period of time for recordkeeping and reporting purposes where the last day would fall on a Saturday, Sunday, or Federal holiday, the period shall run until the close of business of the next business day.

Electric Arc Furnace means a furnace equipped with electrodes used to produce carbon steels and alloy steels primarily by recycling ferrous scrap.

Exceedance means a reading in excess of an applicable opacity or emissions limitation.

Ladle Metallurgy Furnace means a furnace used to refine molten steel into specialty grades while keeping the steel in the ladle.

Ladle/Tundish Preheaters means equipment used to preheat ladles or tundishes to minimize temperature drop prior to use in iron or molten steel refinement.

Reheat Furnace means a furnace used to heat steel product to temperatures at which it will be suitable for deformation and further processing.

Steel Production Cycle means the operations conducted within the basic oxygen process furnace shop that are required to produce each batch of steel, including scrap charging, preheating, hot metal charging, primary oxygen blowing, sampling, (vessel turndown and turnup), additional oxygen blowing, tapping, and deslagging. The steel production cycle begins when the scrap is charged to the furnace and ends three minutes after the slag is emptied from the vessel into the slag pot.

Taconite production kiln means a furnace designed to dry and indurate taconite concentrates to create taconite pellets.

Vacuum degasser means a unit operated within an iron and steel facility to expose molten steel at low pressure to remove certain gases during steel refinement.

(b) *Applicability* The requirements of this section apply to each new or existing emissions unit at an iron and steel mill or ferroalloy manufacturing facility that directly emits or has the potential to emit 100 tons per year or more of NO_X, and to each BOF Shop containing two or more such units that collectively emit or have the potential to emit 100 tons per year or more of NO_X, and that is located within any of the States listed in § 52.40(a)(1)(ii), including Indian country located within the borders of any such State(s).

(c) *Emissions Limitations and Requirements.* Beginning with the 2026 ozone season and in each ozone season thereafter, the emissions limitations in the following table must be met on a 3-hour rolling average.

TABLE 1 TO PARAGRAPH (c)

Emission unit	NO_X Emissions standard or control requirement
Blast Furnace	0.03 lb/mmBtu.
Basic Oxygen Process Furnace	0.07 lb/ton steel.
Electric Arc Furnace	0.15 lb/ton steel.
Ladle/tundish Preheaters	0.06 lb/mmBtu.
Reheat furnace	0.05 lb/mmBtu.
Annealing Furnace	0.06 lb/mmBtu.
Vacuum Degasser	0.03 lb/mmBtu.
Ladle Metallurgy Furnace	0.1 lb/ton steel.
Taconite Production Kilns	Install and operate low NO_X burners as required by 2013 and 2016 Minnesota FIPs. 40 CFR § 52.1183.
Coke Ovens (charging)	0.15 lb/ton of coal charged.
Coke Oven push cars and pushing-charging machines (pushing)	0.015 lb/ton of coal pushed.

TABLE 1 TO PARAGRAPH (c)—Continued

Emission unit	NO_X Emissions standard or control requirement
Boilers—Coal, blast furnace gas, and coke oven gas	0.20 lb/mmBtu.
Boilers—Residual oil	0.20 lb/mmBtu.
Boilers—Distillate oil	0.12 lb/mmBtu.
Boilers—Natural gas	0.08 lb/mmBtu.

(d) *Compliance and Monitoring Requirements*—(1) *Compliance Requirements* (i) Each affected unit identified in Table 1 to paragraph (c) of this section must design, install, maintain, and continuously operate NO_X control devices as necessary to achieve emissions limits set forth in Table 1 to paragraph (c) of this section in a manner consistent with good air pollution control practices as described in 40 CFR 63.6(e).

(A) If you are the owner or operator of an affected unit not identified in paragraph (d)(1)(i)(B) of this section, you must submit to EPA a work plan for each affected unit within 180 days of the effective date of this rule identifying how each affected unit will comply with the emissions limits set forth in Table 1 to paragraph (c) of this section. Each work plan must include identification of the control device selected and the phased construction timeframe by which you will design, install, and consistently operate the device.

(B) For each taconite production kiln affected by this rule, you must install, maintain, and continuously operate low-NO_X burners to reduce existing average NO_X emissions from the facility by 40% during all periods of kiln operation.

(*1*) If you have already installed low-NO_X burners as required by the 2013 or 2016 Minnesota Regional Haze Federal Implementation Plans,[352] then you must submit a report to EPA within 180 days of the effective date of this rule demonstrating that the low-NO_X burner is designed to achieve 40% reduction of kiln NO_X emissions.

(*2*) If you have not yet installed low-NO_X burners as required by the 2013 or 2016 Minnesota Regional Haze Federal Implementation Plans, then you must submit a work plan identifying the low-NO_X burner selected and the phased construction timeframe by which you will design, install, and consistently operate the burner. Each work plan shall include performance test results obtained within five years of the effective date of this rule to be used as baseline emission testing data providing the basis for required emission reductions.

(2) *Monitoring Requirements* (i) For each unit identified in Table 1 to paragraph (c) of this section of this rule, you must install, operate, and maintain a NO_X continuous emission monitoring system (CEMS) to monitor compliance with the emissions limits set forth in Table 1 to paragraph (c) of this section. Each CEMS shall be installed and operated in accordance with requirements set forth at 40 CFR part 60, appendix B.

(ii) You must conduct a performance evaluation of each CEMS according to the requirements in 40 CFR 63.8 and according to 40 CFR part 60, appendix B.

(iii) You must notify EPA in writing of your intention to conduct a performance test at least 60 calendar days before the performance test is initially scheduled to begin in accordance with 40 CFR 63.7 (b).

(iv) As specified in 40 CFR 63.8(c)(4)(ii), each CEMS must complete a minimum of one cycle of operation (sampling, analyzing, and data recording) for each successive 15-minute period. You must have at least two data points, each representing a different 15-minute period within the same hour, to have a valid hour of data.

(v) All CEMS data must be reduced as specified in 40 CFR 63.8(g)(2) and recorded as NO_X in parts per million by volume, dry basis (ppmvd).

(vi) Proper maintenance. You must maintain the CEMS equipment at all times that the unit is operating, including but not limited to, maintaining necessary parts for routine repairs of the monitoring equipment.

(vii) You must conduct all monitoring in continuous operation at all times that the unit is operating, except for, as applicable, monitoring malfunctions, associated repairs, and required quality assurance or control activities (including, as applicable, calibration drift checks and required zero and high-level adjustments). Quality assurance or control activities must be performed according to procedure 1 of 40 CFR part 60, appendix F.

(viii) Data recorded during monitoring malfunctions, associated repairs, out-of-control periods, and required quality assurance or control activities should not be used for purposes of calculating data averages. You must use all of the data collected from all other periods in assessing compliance. A monitoring malfunction is any sudden, infrequent, not reasonably preventable failure of the monitoring equipment to provide valid data. Monitoring failures that are caused in part by poor maintenance or careless operation are not malfunctions. Any period for which the monitoring system is out-of-control and data are not available for required calculations constitutes a deviation from the monitoring requirements.

(e) *Recordkeeping requirements* (1) You shall maintain records of the following information for each day the affected unit operates:

(i) Calendar date;

(ii) The average hourly NO_X emission rates measured or predicted;

(iii) The 30-day average NO_X emission rates calculated at the end of each affected unit operating day from the measured or predicted hourly NO_X emission rates for the preceding 30 steam generating unit operating days;

(iv) Identification of the affected unit operating days when the calculated 30-day average NO_X emission rates are in excess of the applicable NO_X emission limit in Table 1 to paragraph (c) of this section with the reasons for such excess emissions as well as a description of corrective actions taken;

(v) Identification of the affected unit operating days for which pollutant data have not been obtained, including reasons for not obtaining sufficient data and a description of corrective actions taken;

(vi) Identification of the times when emission data have been excluded from the calculation of average emission rates and the reasons for excluding data;

(viii) Identification of the times when the pollutant concentration exceeded full span of the CEMS;

(ix) Description of any modifications to the CEMS that could affect the ability of the CEMS to comply with Performance Specification 2 or 3 in appendix B of 40 CFR part 60; and

(x) Results of daily CEMS drift tests and quarterly accuracy assessments as required under Procedure 1 of 40 CFR part 60, appendix F.

[352] *https://archive.epa.gov/reg5oair/taconite/web/html/index.html.*

(2) Any records required to be maintained by this section that are submitted electronically via the EPA's CEDRI may be maintained in electronic format. This ability to maintain electronic copies does not affect the requirement for facilities to make records, data, and reports available upon request to the EPA as part of an on-site compliance evaluation.

(f) *Reporting requirements* (1) Within 180 days of the effective date of this rule, you shall submit a work plan in accordance with requirements set forth in paragraph (d)(1)(i)(A) of this section, including identification of the control device selected and the phased construction timeframe by which you will design, install, and consistently operate the device. For taconite kilns subject to paragraph (d)(1)(i)(B)(2) of this section each work plan shall include performance test results obtained within five years of the effective date of this rule to be used as baseline emission testing data providing the basis for required emission reductions.

(2) By no later than March 30, 2026, each owner/operator of an affected unit shall submit a final report certifying installation of each selected control device has completed. Each such report shall contain dates of final construction and relevant performance testing, where applicable, demonstrating compliance with limits set forth in Table 1 to paragraph (c) of this section.

(3) Within 60 days after the date of completing each performance test required by this section, you must submit the results of the performance test or performance evaluation of the CEMS following the procedures specified in paragraphs (c)(3)(i) through (iii) of this section:

(i) *Data collected using test methods supported by the EPA's ERT as listed on the EPA's ERT website (https://www.epa.gov/electronic-reporting-air-emissions/electronic-reporting-tool-ert) at the time of the test.* Submit the results of the performance test to the EPA via the CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section, which can be accessed through the EPA's CDX (*https://cdx.epa.gov/*). The data must be submitted in a file format generated using the EPA's ERT. Alternatively, you may submit an electronic file consistent with the XML schema listed on the EPA's ERT website.

(ii) *Data collected using test methods that are not supported by the EPA's ERT as listed on the EPA's ERT website at the time of the test.* The results of the performance test must be included as an attachment in the ERT or an alternate electronic file consistent with the XML schema listed on the EPA's ERT website. Submit the ERT generated package or alternative file to the EPA via CEDRI.

(iii) *CBI. Do not use CEDRI to submit information you claim as CBI.* Anything submitted using CEDRI cannot later be claimed CBI. Although we do not expect persons to assert a claim of CBI, if you wish to assert a CBI claim for some of the information submitted under paragraph (f)(1)(i) or (ii) of this section, you must submit a complete file, including information claimed to be CBI, to the EPA. The file must be generated using the EPA's ERT or an alternate electronic file consistent with the XML schema listed on the EPA's ERT website. Submit the file on a compact disc, flash drive, or other commonly used electronic storage medium and clearly mark the medium as CBI. Mail the electronic medium to U.S. EPA/OAQPS/CORE CBI Office, MD C404–02, 4930 Old Page Rd., Durham, NC 27703. The same file with the CBI omitted must be submitted to the EPA via the EPA's CDX as described in paragraphs (f)(1)(i) and (ii). All CBI claims must be asserted at the time of submission. Furthermore, under CAA section 114(c), emissions data is not entitled to confidential treatment, and the EPA is required to make emissions data available to the public. Thus, emissions data will not be protected as CBI and will be made publicly available.

(4) You are required to submit excess emission reports for any excess emissions that occurred during the reporting period. Excess emissions are defined as any calculated 30-day rolling average NO_X emission rate, as determined under paragraph (c)(3)(iii) of this section, that exceeds the applicable emission limit in paragraph (c) of this section. Excess emission reports must be submitted in PDF format to the EPA via CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section.

(5) If you own or operate an affected unit subject to the continuous monitoring requirements for NO_X under paragraph (d) of this section, you shall submit reports containing the information recorded under paragraph (d) as described in paragraph (e)(6) of this section. Compliance reports for continuous monitoring must be submitted in PDF format to the EPA via CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section.

(6) If you own or operate an affected unit, you must submit electronic quarterly reports no later than 30 days after the end of the calendar quarter. The reports shall be accompanied by a certification from the owner or operator indicating whether the affected unit was in compliance with the applicable emission limits and minimum data requirements of this section during the reporting period. These quarterly reports must be submitted in PDF format to the EPA via CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section.

(7) If you are required to electronically submit a report through CEDRI in the EPA's CDX, you may assert a claim of EPA system outage for failure to timely comply with that reporting requirement. To assert a claim of EPA system outage, you must meet the requirements outlined in paragraphs (f)(7)(i) through (vii) of this section.

(i) You must have been or will be precluded from accessing CEDRI and submitting a required report within the time prescribed due to an outage of either the EPA's CEDRI or CDX systems.

(ii) The outage must have occurred within the period of time beginning five business days prior to the date that the submission is due.

(iii) The outage may be planned or unplanned.

(iv) You must submit notification to the Administrator in writing as soon as possible following the date you first knew, or through due diligence should have known, that the event may cause or has caused a delay in reporting.

(v) You must provide to the Administrator a written description identifying:

(A) The date(s) and time(s) when CDX or CEDRI was accessed and the system was unavailable;

(B) A rationale for attributing the delay in reporting beyond the regulatory deadline to EPA system outage;

(C) A description of measures taken or to be taken to minimize the delay in reporting; and

(D) The date by which you propose to report, or if you have already met the reporting requirement at the time of the notification, the date you reported.

(vi) The decision to accept the claim of EPA system outage and allow an extension to the reporting deadline is solely within the discretion of the Administrator.

(vii) In any circumstance, the report must be submitted electronically as soon as possible after the outage is resolved.

(8) If you are required to electronically submit a report through CEDRI in the EPA's CDX, you may assert a claim of force majeure for failure to timely comply with that

reporting requirement. To assert a claim of force majeure, you must meet the requirements outlined in paragraphs (f)(8)(i) through (v) of this section.

(i) You may submit a claim if a force majeure event is about to occur, occurs, or has occurred or there are lingering effects from such an event within the period of time beginning five business days prior to the date the submission is due. For the purposes of this section, a force majeure event is defined as an event that will be or has been caused by circumstances beyond the control of the affected facility, its contractors, or any entity controlled by the affected facility that prevents you from complying with the requirement to submit a report electronically within the time period prescribed. Examples of such events are acts of nature (*e.g.,* hurricanes, earthquakes, or floods), acts of war or terrorism, or equipment failure or safety hazard beyond the control of the affected facility (*e.g.,* large scale power outage).

(ii) You must submit notification to the Administrator in writing as soon as possible following the date you first knew, or through due diligence should have known, that the event may cause or has caused a delay in reporting.

(iii) You must provide to the Administrator:

(A) A written description of the force majeure event;

(B) A rationale for attributing the delay in reporting beyond the regulatory deadline to the force majeure event;

(C) A description of measures taken or to be taken to minimize the delay in reporting; and

(D) The date by which you propose to report, or if you have already met the reporting requirement at the time of the notification, the date you reported.

(iv) The decision to accept the claim of force majeure and allow an extension to the reporting deadline is solely within the discretion of the Administrator.

(v) In any circumstance, the reporting must occur as soon as possible after the force majeure event occurs.

§ 52.44 What are the requirements of the Federal Implementation Plans (FIPs) relating to ozone season emissions of nitrogen oxides from the Glass and Glass Product Manufacturing Industry?

(a) *Definitions.* All terms not defined herein shall have the meaning given them in the Act and in subpart A of part 60.

Affected units means a glass manufacturing furnace meeting the applicability criteria of this section.

All-electric melter means a glass melting furnace in which all the heat required for melting is provided by electric current from electrodes submerged in the molten glass, although some fossil fuel may be charged to the furnace as raw material only.

Borosilicate recipe means glass product composition of the following approximate ranges of weight proportions: 60 to 80 percent silicon dioxide, 4 to 10 percent total R_2O (*e.g.,* Na_2O and K_2O), 5 to 35 percent boric oxides, and 0 to 13 percent other oxides.

Container glass means glass made of soda-lime recipe, clear or colored, which is pressed and/or blown into bottles, jars, ampoules, and other products listed in Standard Industrial Classification 3221 (SIC 3221).

Experimental furnace means a glass melting furnace with the sole purpose of operating to evaluate glass melting processes, technologies, or glass products. An experimental furnace does not produce glass that is sold (except for further research and development purposes) or that is used as a raw material for nonexperimental furnaces.

Flat glass means glass made of soda-lime recipe and produced into continuous flat sheets and other products listed in SIC 3211.

Glass melting furnace means a unit comprising a refractory vessel in which raw materials are charged, melted at high temperature, refined, and conditioned to produce molten glass. The unit includes foundations, superstructure and retaining walls, raw material charger systems, heat exchangers, melter cooling system, exhaust system, refractory brick work, fuel supply and electrical boosting equipment, integral control systems and instrumentation, and appendages for conditioning and distributing molten glass to forming apparatuses. The forming apparatuses, including the float bath used in flat glass manufacturing and flow channels in wool fiberglass and textile fiberglass manufacturing, are not considered part of the glass melting furnace.

Glass produced means the weight of the glass pulled from the glass melting furnace.

Hand glass melting furnace means a glass melting furnace where the molten glass is removed from the furnace by a glassworker using a blowpipe or a pontil.

Lead recipe means glass product composition of the following ranges of weight proportions: 50 to 60 percent silicon dioxide, 18 to 35 percent lead oxides, 5 to 20 percent total R_2O (*e.g.,* Na_2O and K_2O), 0 to 8 percent total R_2O_3 (*e.g.,* Al_2O_3), 0 to 15 percent total RO (*e.g.,* CaO, MgO), other than lead oxide, and 5 to 10 percent other oxides.

Pressed and blown glass means glass which is pressed, blown, or both, including textile fiberglass, noncontinuous flat glass, noncontainer glass, and other products listed in SIC 3229. It is separated into: Glass of borosilicate recipe, Glass of soda-lime and lead recipes, and Glass of opal, fluoride, and other recipes.

Raw material means minerals, such as silica sand, limestone, and dolomite; inorganic chemical compounds, such as soda ash (sodium carbonate), salt cake (sodium sulfate), and potash (potassium carbonate); metal oxides and other metal-based compounds, such as lead oxide, chromium oxide, and sodium antimonate; metal ores, such as chromite and pyrolusite; and other substances that are intentionally added to a glass manufacturing batch and melted in a glass melting furnace to produce glass. Metals that are naturally-occurring trace constituents or contaminants of other substances are not considered to be raw materials.

Rebricking means cold replacement of damaged or worn refractory parts of the glass melting furnace. Rebricking includes replacement of the refractories comprising the bottom, sidewalls, or roof of the melting vessel; replacement of refractory work in the heat exchanger; replacement of refractory portions of the glass conditioning and distribution system.

Soda-lime recipe means glass product composition of the following ranges of weight proportions: 60 to 75 percent silicon dioxide, 10 to 17 percent total R_2O (*e.g.,* Na_2O and K_2O), 8 to 20 percent total RO but not to include any PbO (*e.g.,* CaO, and MgO), 0 to 8 percent total R_2O_3 (*e.g.,* Al_2O_3), and 1 to 5 percent other oxides.

Textile fiberglass means fibrous glass in the form of continuous strands having uniform thickness.

Wool fiberglass means fibrous glass of random texture, including fiber glass insulation, and other products listed in SIC 3296.

(b) *Applicability* You are subject to the requirements under this section if you own or operate a new or existing glass manufacturing furnace that directly emits or has the potential to emit 100 tons per year or more of NO_X and is located within any of the States listed in § 52.40(a)(1)(ii), including Indian country located within the borders of any such State(s).

(c) *Emissions limitations* If you own or operate an affected unit you are subject to the NO_X emissions limits in the following table beginning with the 2026 ozone season and in each ozone season thereafter:

TABLE 1 TO PARAGRAPH (c)

Furnace type	Proposed NO_X emissions limit (lb/ton of glass produced)
Container Glass Manufacturing Furnace	4.0
Pressed/Blown Glass Manufacturing Furnace or Fiberglass Manufacturing Furnace	4.0
Flat Glass Manufacturing Furnace	9.2

(d) *Testing and Monitoring Requirements* If you own or operate an affected unit you must conduct performance tests, on a semiannual basis, in accordance with the applicable reference test methods of 40 CFR part 60, Appendix A, any alternative test method approved by EPA as of April 6, 2022 under 40 CFR 59.104(f), 60.8(b)(3), 61.13(h)(1)(ii), 63.7(e)(2)(ii), or 65.158(a)(2) and available at EPA's website (*https://www.epa.gov/emc/broadly-applicable-approved-alternative-test-methods*), or other methods and procedures approved by EPA through notice-and-comment rulemaking. Direct measurement or material balance using good engineering practice shall be used to determine the amount of glass pulled during the performance test. The rate of glass produced is defined as the weight of glass pulled from the affected facility during the performance test divided by the number of hours taken to perform the performance test.

(1) Owners or operators of affected units must calculate and record the 30-operating day rolling emission rate of NO_X as the total of all hourly emissions data for a glass manufacturing furnace in the preceding 30 days, divided by the total tons of glass produced in that furnace during the same 30-operating day period. If a continuous emission monitoring system has not been installed on the affected unit, the owner or operator shall conduct the following steps:

(A) *Step 1:* determine the average pounds of NO_X emitted per hour by averaging three one-hour tests,

(B) *Step 2:* determine the average tons of glass removed per hour during the same time period as the three one-hour tests in step 1,

(C) *Step 3:* divide the average pounds of NO_X emitted per hour determined in step 1 by the average tons of glass removed per hour determined in step 2,

(D) *Step 4:* compare the quotient to the emission limits specified at § 52.44(c)(1).

(2) If a continuous emission monitoring system has been installed on the affected unit, on a daily basis the owner or operator shall conduct the following steps:

(A) *Step 1:* determine the average pounds of NO_X emitted per day,

(B) *Step 2:* determine the tons of glass removed per day,

(C) *Step 3:* divide the average pounds of NO_X emitted per day determined in step (1) by the tons of glass removed per day determined in step (2). The quotient is pounds of NO_X emitted per ton of glass removed; and

(D) *Step 4:* compare the quotient to the emission limit specified at § 52.44(c)(1).

(e) *Recordkeeping requirements* (1) If you own or operate an affected unit, you must retain records of the calculations and measurements as required in paragraph (e) of this section for 5-year period specified in 52.40(b)(3). You must record the results of each inspection and maintenance proposed rule in a logbook (written or electronic format). You shall keep the logbook onsite and make the logbook available to the permitting authority upon request, consistent with the requirements of 40 CFR part 63, subpart SSSSSS, § 63.11457(c).

(2) Any records required to be maintained by this section that are submitted electronically via the EPA's CEDRI may be maintained in electronic format. This ability to maintain electronic copies does not affect the requirement for facilities to make records, data, and reports available upon request to the EPA as part of an on-site compliance evaluation.

(f) *Reporting requirements* (1) Within 60 days after the date of completing each performance test required by this section, you must submit the results of the performance test following the procedures specified in paragraphs (e)(1)(i) through (iii) of this section:

(i) *Data collected using test methods supported by the EPA's ERT as listed on the EPA's ERT website (https://www.epa.gov/electronic-reporting-air-emissions/electronic-reporting-tool-ert) at the time of the test.* Submit the results of the performance test to the EPA via the CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section, which can be accessed through the EPA's CDX (*https://cdx.epa.gov/*). The data must be submitted in a file format generated using the EPA's ERT. Alternatively, you may submit an electronic file consistent with the XML schema listed on the EPA's ERT website.

(ii) *Data collected using test methods that are not supported by the EPA's ERT as listed on the EPA's ERT website at the time of the test.* The results of the performance test must be included as an attachment in the ERT or an alternate electronic file consistent with the XML schema listed on the EPA's ERT website. Submit the ERT generated package or alternative file to the EPA via CEDRI.

(iii) *CBI. Do not use CEDRI to submit information you claim as CBI.* Anything submitted using CEDRI cannot later be claimed CBI. Although we do not expect persons to assert a claim of CBI, if you wish to assert a CBI claim for some of the information submitted under paragraph (f)(1)(i) or (ii) of this section, you must submit a complete file, including information claimed to be CBI, to the EPA. The file must be generated using the EPA's ERT or an alternate electronic file consistent with the XML schema listed on the EPA's ERT website. Submit the file on a compact disc, flash drive, or other commonly used electronic storage medium and clearly mark the medium as CBI. Mail the electronic medium to U.S. EPA/OAQPS/CORE CBI Office, MD C404–02, 4930 Old Page Rd., Durham, NC 27703. The same file with the CBI omitted must be submitted to the EPA via the EPA's CDX as described in paragraphs (f)(1)(i) and (ii). All CBI claims must be asserted at the time of submission. Furthermore, under CAA section 114(c), emissions data is not entitled to confidential treatment, and the EPA is required to make emissions data available to the public. Thus, emissions data will not be protected as CBI and will be made publicly available.

(2) If you own or operate an affected unit, you shall submit a semi-annual report, at least every six months, in PDF format to the EPA via CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section.

(3) If you are required to electronically submit a report through CEDRI in the EPA's CDX, you may assert a claim of EPA system outage for failure to timely comply with that reporting requirement. To assert a claim of EPA system outage, you must meet the requirements outlined in paragraphs (f)(3)(i) through (vii) of this section.

(i) You must have been or will be precluded from accessing CEDRI and submitting a required report within the time prescribed due to an outage of either the EPA's CEDRI or CDX systems.

(ii) The outage must have occurred within the period of time beginning five business days prior to the date that the submission is due.

(iii) The outage may be planned or unplanned.

(iv) You must submit notification to the Administrator in writing as soon as possible following the date you first knew, or through due diligence should have known, that the event may cause or has caused a delay in reporting.

(v) You must provide to the Administrator a written description identifying:

(A) The date(s) and time(s) when CDX or CEDRI was accessed and the system was unavailable;

(B) A rationale for attributing the delay in reporting beyond the regulatory deadline to EPA system outage;

(C) A description of measures taken or to be taken to minimize the delay in reporting; and

(D) The date by which you propose to report, or if you have already met the reporting requirement at the time of the notification, the date you reported.

(vi) The decision to accept the claim of EPA system outage and allow an extension to the reporting deadline is solely within the discretion of the Administrator.

(vii) In any circumstance, the report must be submitted electronically as soon as possible after the outage is resolved.

(4) If you are required to electronically submit a report through CEDRI in the EPA's CDX, you may assert a claim of force majeure for failure to timely comply with that reporting requirement. To assert a claim of force majeure, you must meet the requirements outlined in paragraphs (f)(4)(i) through (v) of this section.

(i) You may submit a claim if a force majeure event is about to occur, occurs, or has occurred or there are lingering effects from such an event within the period of time beginning five business days prior to the date the submission is due. For the purposes of this section, a force majeure event is defined as an event that will be or has been caused by circumstances beyond the control of the affected facility, its contractors, or any entity controlled by the affected facility that prevents you from complying with the requirement to submit a report electronically within the time period prescribed. Examples of such events are acts of nature (*e.g.,* hurricanes, earthquakes, or floods), acts of war or terrorism, or equipment failure or safety hazard beyond the control of the affected facility (*e.g.,* large scale power outage).

(ii) You must submit notification to the Administrator in writing as soon as possible following the date you first knew, or through due diligence should have known, that the event may cause or has caused a delay in reporting.

(iii) You must provide to the Administrator:

(A) A written description of the force majeure event;

(B) A rationale for attributing the delay in reporting beyond the regulatory deadline to the force majeure event;

(C) A description of measures taken or to be taken to minimize the delay in reporting; and

(D) The date by which you propose to report, or if you have already met the reporting requirement at the time of the notification, the date you reported.

(iv) The decision to accept the claim of force majeure and allow an extension to the reporting deadline is solely within the discretion of the Administrator.

(v) In any circumstance, the reporting must occur as soon as possible after the force majeure event occurs.

§ 52.45 What are the requirements of the Federal Implementation Plans (FIPs) relating to ozone season emissions of nitrogen oxides from the Basic Chemical Manufacturing, Petroleum and Coal Products Manufacturing, and Pulp, Paper, and Paperboard Mills Industries?

(a) *Definitions.* All terms not defined herein shall have the meaning given them in the Act and in subpart A of 40 CFR part 60.

Affected unit means an industrial boiler meeting the applicability criteria of this section.

(b) *Applicability.* (1) The requirements of this section apply to each new or existing boiler with a design capacity of 100 mmBtu/hr or greater fueled by coal, residual oil, distillate oil, or natural gas, located at sources that are within the Basic Chemical Manufacturing industry (NAICS code 3251xx), the Petroleum and Coal Products Manufacturing industry (NAICS code 3241xx), and the Pulp, Paper, and Paperboard industry (NAICS code 3221xx), and which is located within any of the States listed in § 52.40(a)(1)(ii), including Indian country located within the borders of any such State(s).

(c) *Emission limitations.* Beginning with the 2026 ozone season and in each ozone season thereafter, the following emission limits apply, based on a 30-day averaging time:

(1) Coal-fired industrial boilers: 0.20 lbs NO_X/mmBtu;

(2) Residual oil-fired industrial boilers: 0.15 lbs NO_X/mmBtu;

(3) Distillate oil-fired industrial boilers: 0.12 lbs NO_X/mmBtu; and

(4) Natural gas-fired industrial boilers: 0.08 lbs NO_X/mmBtu.

(d) *Initial compliance testing.* (1) To determine compliance with the emission limits for NO_X identified in paragraph (c) of this section, you shall conduct an initial compliance test as described in 40 CFR § 60.8 using the continuous system for monitoring NO_X specified by EPA Test Method 7E—Determination of Nitrogen Oxide Emissions from Stationary Sources (Instrumental Analyzer Procedure), as described at 40 CFR part 60, Appendix A–4. In lieu of the timing of the compliance test described in 40 CFR 60.8(a), the test shall be conducted within 90 days from the installation of the pollution control equipment used to comply with the NO_X emission limits in paragraph (c) of this section.

(2) For the initial compliance test, NO_X emissions from the affected unit shall be monitored for 30 successive operating days and the 30-day average emission rate will be used to determine compliance with the NO_X emission limits in paragraph (c) of this section. The 30-day average emission rate is calculated as the average of all hourly emission data recorded by the monitoring system during the 30-day test period.

(e) *Monitoring requirements.* (1) The NO_X emission limits in paragraph (c) of this section shall apply at all times.

(2) You shall install, calibrate, maintain, and operate a continuous emissions monitoring system (CEMS) for measuring NO_X emissions and either oxygen (O_2) or carbon dioxide (CO_2), unless the Administrator has approved a request from the you to use an alternative monitoring technique under paragraph (e)(8) of this section. If you have previously installed a NO_X emission rate CEMS to meet the requirements of 40 CFR part 75 and continue to meet the ongoing requirements of 40 CFR part 75, that CEMS may be used to meet the monitoring requirements of this section.

(3) The CEMS required under paragraph (e)(2) of this section shall be operated and data recorded during all periods of operation of the affected unit except for CEMS breakdowns and repairs. Data shall be recorded during calibration checks and zero and span adjustments.

(4) The 1-hour average NO_X emission rates measured by the CEMS required by paragraph (e)(2) of this section shall be expressed in terms of lbs/mmBtu heat input and shall be used to calculate the average emission rates under 40 CFR 52.45(c).

(5) Following the date on which the initial compliance test is completed, you shall determine compliance with the applicable NO_X emission limit in paragraph (c) of this section on a continuous basis using a 30-day rolling

average emission rate unless the affected unit monitors emissions by means of an alternative monitoring procedure approved pursuant to paragraph (e)(8) of this section. A new 30-day rolling average emission rate is calculated for each operating day as the average of all the hourly NO_X emission data for the preceding 30 operating days.

(6) The procedures under 40 CFR 60.13 shall be followed for installation, evaluation, and operation of the continuous monitoring systems. Additionally, the span value for units combusting coal shall be 1,000 ppm NO_X, and for units combusting oil or gas the span value shall be 500 ppm NO_X. As an alternative to meeting the span value requirements stated above, you may elect to use the NO_X span values determined according to section 2.1.2 in appendix A to 40 CFR part 75.

(7) When NO_X emission data are not obtained because of CEMS breakdowns, repairs, calibration checks and zero and span adjustments, emission data will be obtained by using standby monitoring systems, Method 7 of 40 CFR part 60, Method 7A of 40 CFR part 60, or other approved reference methods to provide emission data for a minimum of 75 percent of the operating hours in each affected unit operating day, in at least 22 out of 30 successive operating days.

(8) Installation of a CEMS for NO_X may be delayed until after the initial performance test has been conducted. If you demonstrate during the performance test that emissions of NO_X are less than 70 percent of the applicable emission limit in paragraph (c) of this section, a CEMS for measuring NO_X emissions is not required. If you demonstrate its boiler emits less than 70 percent of the applicable emission limit chooses to not install a CEMS, you must submit a written request to the Administrator that documents the results of the initial performance test and includes an alternative monitoring procedure that will be used to track compliance with the applicable NO_X emission limit(s) in paragraph (c) of this section. The Administrator will consider the request and, following public notice and comment, may approve the alternative monitoring procedure with or without revision, or disapprove the request. Upon receipt of a disapproved request, you will have one year to install a CEMS in accordance with the provisions for CEMS described in paragraph (e) of this section.

(f) *Recordkeeping requirements* (1) You shall record and maintain records of the amounts of each fuel combusted during each calendar month.

(2) You shall maintain records of the following information for each day the affected unit operates:

(i) Calendar date;

(ii) The average hourly NO_X emission rates (expressed as lbs NO_2/mmBtu heat input) measured or predicted;

(iii) The 30-day average NO_X emission rates calculated at the end of each affected unit operating day from the measured or predicted hourly NO_X emission rates for the preceding 30 steam generating unit operating days;

(iv) Identification of the affected unit operating days when the calculated 30-day average NO_X emission rates are in excess of the applicable NO_X emission limit in paragraph (c) of this section with the reasons for such excess emissions as well as a description of corrective actions taken;

(v) Identification of the affected unit operating days for which pollutant data have not been obtained, including reasons for not obtaining sufficient data and a description of corrective actions taken;

(vi) Identification of the times when emission data have been excluded from the calculation of average emission rates and the reasons for excluding data;

(vii) Identification of ''F'' factor used for calculations, method of determination, and type of fuel combusted;

(viii) Identification of the times when the pollutant concentration exceeded full span of the CEMS;

(ix) Description of any modifications to the CEMS that could affect the ability of the CEMS to comply with Performance Specification 2 or 3 in appendix B of 40 CFR part 60; and

(x) Results of daily CEMS drift tests and quarterly accuracy assessments as required under Procedure 1 of 40 CFR part 60, appendix F.

(3) Any records required to be maintained by this section that are submitted electronically via the EPA's CEDRI may be maintained in electronic format. This ability to maintain electronic copies does not affect the requirement for facilities to make records, data, and reports available upon request to the EPA as part of an on-site compliance evaluation.

(g) *Reporting requirements.* (1) Within 60 days after the date of completing each performance test required by this section, you must submit the results of the performance test or performance evaluation of the CEMS following the procedures specified in paragraphs (g)(i) through (iii) of this section:

(i) *Data collected using test methods supported by the EPA's ERT as listed on the EPA's ERT website (https://www.epa.gov/electronic-reporting-air-emissions/electronic-reporting-tool-ert) at the time of the test.* Submit the results of the performance test to the EPA via the CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section, which can be accessed through the EPA's CDX (*https://cdx.epa.gov/*). The data must be submitted in a file format generated using the EPA's ERT. Alternatively, you may submit an electronic file consistent with the XML schema listed on the EPA's ERT website.

(ii) *Data collected using test methods that are not supported by the EPA's ERT as listed on the EPA's ERT website at the time of the test.* The results of the performance test must be included as an attachment in the ERT or an alternate electronic file consistent with the XML schema listed on the EPA's ERT website. Submit the ERT generated package or alternative file to the EPA via CEDRI.

(iii) *CBI. Do not use CEDRI to submit information you claim as CBI.* Anything submitted using CEDRI cannot later be claimed CBI. Although we do not expect persons to assert a claim of CBI, if you wish to assert a CBI claim for some of the information submitted under paragraph (g)(1)(i) or (ii) of this section, you must submit a complete file, including information claimed to be CBI, to the EPA. The file must be generated using the EPA's ERT or an alternate electronic file consistent with the XML schema listed on the EPA's ERT website. Submit the file on a compact disc, flash drive, or other commonly used electronic storage medium and clearly mark the medium as CBI. Mail the electronic medium to U.S. EPA/OAQPS/CORE CBI Office, MD C404–02, 4930 Old Page Rd., Durham, NC 27703. The same file with the CBI omitted must be submitted to the EPA via the EPA's CDX as described in paragraphs (g)(1)(i) and (ii) of this section. All CBI claims must be asserted at the time of submission. Furthermore, under CAA section 114(c), emissions data is not entitled to confidential treatment, and the EPA is required to make emissions data available to the public. Thus, emissions data will not be protected as CBI and will be made publicly available.

(2) You are required to submit excess emission reports for any excess emissions that occurred during the reporting period. Excess emissions are defined as any calculated 30-day rolling average NO_X emission rate, as determined under paragraph (g)(3)(iii) of this section, that exceeds the applicable emission limit in paragraph (c) of this section. Excess emission reports must be

submitted in PDF format to the EPA via CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section.

(3) If you own or operate an affected unit subject to the continuous monitoring requirements for NO_X under paragraph (e) of this section, you shall submit reports containing the information recorded under paragraph (e) of this section as described in paragraph (g)(2) of this section. Compliance reports for continuous monitoring must be submitted in PDF format to the EPA via CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section.

(4) If you own or operate an affected unit, you must submit electronic quarterly reports no later than 30 days after the end of the calendar quarter. The reports shall be accompanied by a certification from the owner or operator indicating whether the affected unit was in compliance with the applicable emission limits and minimum data requirements of this section during the reporting period. These quarterly reports must be submitted in PDF format to the EPA via CEDRI or analogous electronic reporting approach provided by the EPA to report data required by this section.

(5) If you are required to electronically submit a report through CEDRI in the EPA's CDX, you may assert a claim of EPA system outage for failure to timely comply with that reporting requirement. To assert a claim of EPA system outage, you must meet the requirements outlined in paragraphs (g)(5)(i) through (vii) of this section.

(i) You must have been or will be precluded from accessing CEDRI and submitting a required report within the time prescribed due to an outage of either the EPA's CEDRI or CDX systems.

(ii) The outage must have occurred within the period of time beginning five business days prior to the date that the submission is due.

(iii) The outage may be planned or unplanned.

(iv) You must submit notification to the Administrator in writing as soon as possible following the date you first knew, or through due diligence should have known, that the event may cause or has caused a delay in reporting.

(v) You must provide to the Administrator a written description identifying:

(A) The date(s) and time(s) when CDX or CEDRI was accessed and the system was unavailable;

(B) A rationale for attributing the delay in reporting beyond the regulatory deadline to EPA system outage;

(C) A description of measures taken or to be taken to minimize the delay in reporting; and

(D) The date by which you propose to report, or if you have already met the reporting requirement at the time of the notification, the date you reported.

(vi) The decision to accept the claim of EPA system outage and allow an extension to the reporting deadline is solely within the discretion of the Administrator.

(vii) In any circumstance, the report must be submitted electronically as soon as possible after the outage is resolved.

(6) If you are required to electronically submit a report through CEDRI in the EPA's CDX, you may assert a claim of force majeure for failure to timely comply with that reporting requirement. To assert a claim of force majeure, you must meet the requirements outlined in paragraphs (g)(6)(i) through (v) of this section.

(i) You may submit a claim if a force majeure event is about to occur, occurs, or has occurred or there are lingering effects from such an event within the period of time beginning five business days prior to the date the submission is due. For the purposes of this section, a force majeure event is defined as an event that will be or has been caused by circumstances beyond the control of the affected facility, its contractors, or any entity controlled by the affected facility that prevents you from complying with the requirement to submit a report electronically within the time period prescribed. Examples of such events are acts of nature (*e.g.,* hurricanes, earthquakes, or floods), acts of war or terrorism, or equipment failure or safety hazard beyond the control of the affected facility (*e.g.,* large scale power outage).

(ii) You must submit notification to the Administrator in writing as soon as possible following the date you first knew, or through due diligence should have known, that the event may cause or has caused a delay in reporting.

(iii) You must provide to the Administrator:

(A) A written description of the force majeure event;

(B) A rationale for attributing the delay in reporting beyond the regulatory deadline to the force majeure event;

(C) A description of measures taken or to be taken to minimize the delay in reporting; and

(D) The date by which you propose to report, or if you have already met the reporting requirement at the time of the notification, the date you reported.

(iv) The decision to accept the claim of force majeure and allow an extension to the reporting deadline is solely within the discretion of the Administrator.

(v) In any circumstance, the reporting must occur as soon as possible after the force majeure event occurs.

Subpart B—Alabama

■ 5. Amend § 52.54 by revising paragraphs (b)(2) and (3) and adding paragraphs (b)(4) and (5) to read as follows:

§ 52.54 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(b) * * *

(2) The owner and operator of each source and each unit located in the State of Alabama and Indian country within the borders of the State and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 2 Trading Program in subpart EEEEE of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2017 through 2022. The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the Administrator of a revision to Alabama's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(ii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Alabama's SIP.

(3) The owner and operator of each source and each unit located in the State of Alabama and Indian country within the borders of the State and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the

promulgation of an approval by the Administrator of a revision to Alabama's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Alabama's SIP.

(4) Notwithstanding the provisions of paragraphs (b)(2) and (3) of this section, if, at the time of the approval of Alabama's SIP revision described in paragraph (b)(2) or (3) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 2 allowances or CSAPR NO_X Ozone Season Group 3 allowances under subpart EEEEE or GGGGG, respectively, of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of such subpart authorizing the Administrator to complete the allocation and recordation of such allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(5) Notwithstanding the provisions of paragraph (b)(2) of this section, after 2022 the provisions of § 97.826(c) of this chapter (concerning the transfer of CSAPR NO_X Ozone Season Group 2 allowances between certain accounts under common control), the provisions of § 97.826(e) of this chapter (concerning the conversion of amounts of unused CSAPR NO_X Ozone Season Group 2 allowances allocated for control periods before 2023 to different amounts of CSAPR NO_X Ozone Season Group 3 allowances), and the provisions of § 97.811(e) of this chapter (concerning the recall of CSAPR NO_X Ozone Season Group 2 allowances equivalent in quantity and usability to all such allowances allocated to units in the State and Indian country within the borders of the State for control periods after 2022) shall continue to apply.

Subpart E—Arkansas

■ 6. Amend § 52.184 by:

■ a. Redesignating paragraphs (a) through (c) as paragraphs (a)(1) through (3);

■ b. In newly redesignated paragraph (a)(2), removing "2017 and each subsequent year." and adding in its place "2017 through 2022.", and removing the second sentence;

■ c. Revising newly redesignated paragraph (a)(3); and

■ d. Adding paragraphs (a)(4) and (5) and (b).

The revision and additions read as follows:

§ 52.184 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

(a) * * *

(3) The owner and operator of each source and each unit located in the State of Arkansas and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements will be eliminated by the promulgation of an approval by the Administrator of a revision to Arkansas' State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii), except to the extent the Administrator's approval is partial or conditional.

(4) Notwithstanding the provisions of paragraph (a)(3) of this section, if, at the time of the approval of Arkansas' SIP revision described in paragraph (a)(3) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(5) Notwithstanding the provisions of paragraph (a)(2) of this section, after 2022 the provisions of § 97.826(c) of this chapter (concerning the transfer of CSAPR NO_X Ozone Season Group 2 allowances between certain accounts under common control), the provisions of § 97.826(e) of this chapter (concerning the conversion of amounts of unused CSAPR NO_X Ozone Season Group 2 allowances allocated for control periods before 2023 to different amounts of CSAPR NO_X Ozone Season Group 3 allowances), and the provisions of § 97.811(e) of this chapter (concerning the recall of CSAPR NO_X Ozone Season Group 2 allowances equivalent in quantity and usability to all such allowances allocated to units in the State for control periods after 2022) shall continue to apply.

(b) The owner and operator of each source located in the State of Arkansas and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart F—California

■ 7. Add § 52.284 to read as follows:

§ 52.284 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

The owner and operator of each source located in the State of California and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart I—Delaware

■ 8. Amend § 52.440 by adding paragraph (d) to read as follows:

§ 52.440 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(d)(1) The owner and operator of each source and each unit located in the State of Delaware and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements will be eliminated by the promulgation of an approval by the Administrator of a revision to Delaware's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii), except to the extent the Administrator's approval is partial or conditional.

(2) Notwithstanding the provisions of paragraph (d)(1) of this section, if, at the time of the approval of Delaware's SIP

revision described in paragraph (d)(1) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

Subpart O—Illinois

■ 9. Amend § 52.731 by:
■ a. In paragraph (b)(3), removing ''(b)(2)(v), except'' and adding in its place ''(b)(2)(iii), except''; and
■ b. Adding paragraph (c).

The addition reads as follows:

§ 52.731 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(c) The owner and operator of each source located in the State of Illinois and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart P—Indiana

■ 10. Amend § 52.789 by:
■ a. In paragraph (b)(2), removing ''(b)(2)(iv), except'' and adding in its place ''(b)(2)(ii), except'';
■ b. In paragraph (b)(3), removing ''(b)(2)(v), except'' and adding in its place ''(b)(2)(iii), except''; and
■ c. Adding paragraph (c).

The addition reads as follows:

§ 52.789 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(c) The owner and operator of each source located in the State of Indiana and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart S—Kentucky

■ 11. Amend § 52.940 by:
■ a. In paragraph (b)(3), removing ''(b)(2)(v), except'' and adding in its place ''(b)(2)(iii), except''; and
■ b. Adding paragraph (c).

The addition reads as follows:

§ 52.940 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(c) The owner and operator of each source located in the State of Kentucky and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart T—Louisiana

■ 12. Amend § 52.984 by:
■ a. In paragraph (d)(3), revising the second and third sentences;
■ b. Revising paragraph (d)(4);
■ c. In paragraph (d)(5), adding ''and Indian country within the borders of the State'' after ''in the State''; and
■ d. Adding paragraph (e).

The revision and addition read as follows:

§ 52.984 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(d) * * *

(3) * * * The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the Administrator of a revision to Louisiana's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and(b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Louisiana's SIP.

(4) Notwithstanding the provisions of paragraph (d)(3) of this section, if, at the time of the approval of Louisiana's SIP revision described in paragraph (d)(3) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

* * * * *

(e) The owner and operator of each source located in the State of Louisiana and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart V—Maryland

■ 13. Amend § 52.1084 by:
■ a. In paragraph (b)(3), removing ''(b)(2)(v), except'' and adding in its place ''(b)(2)(iii), except''; and
■ b. Adding paragraph (c).

The addition reads as follows:

§ 52.1084 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(c) The owner and operator of each source located in the State of Maryland and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart X—Michigan

■ 14. Amend § 52.1186 by:
■ a. In paragraph (e)(3), revising the second and third sentences;
■ b. Revising paragraph (e)(4);
■ c. In paragraph (e)(5), adding ''and Indian country within the borders of the State'' after ''in the State''; and
■ d. Adding paragraph (f).

The revision and addition read as follows:

§ 52.1186 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(e) * * *

(3) * * * The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the

Administrator of a revision to Michigan's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and(b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Michigan's SIP.

(4) Notwithstanding the provisions of paragraph (e)(3) of this section, if, at the time of the approval of Michigan's SIP revision described in paragraph (e)(3) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

* * * * *

(f) The owner and operator of each source located in the State of Michigan and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart Y—Minnesota

■ 15. Amend § 52.1240 by adding paragraphs (d) and (e) to read as follows:

§ 52.1240 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(d)(1) The owner and operator of each source and each unit located in the State of Minnesota and Indian country within the borders of the State and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the Administrator of a revision to Minnesota's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Minnesota's SIP.

(2) Notwithstanding the provisions of paragraph (d)(1) of this section, if, at the time of the approval of Minnesota's SIP revision described in paragraph (d)(1) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(e) The owner and operator of each source located in the State of Minnesota and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart Z—Mississippi

■ 16. Amend § 52.1284 by:

■ a. Redesignating paragraphs (a) through (c) as paragraphs (a)(1) through (3);

■ b. In newly redesignated paragraph (a)(2), removing ''2017 and each subsequent year.'' and adding in its place ''2017 through 2022.'', and removing the second and third sentences;

■ c. Revising newly redesignated paragraph (a)(3); and

■ d. Adding paragraphs (a)(4) and (5) and (b).

The revision and additions read as follows:

§ 52.1284 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

(a) * * *

(3) The owner and operator of each source and each unit located in the State of Mississippi and Indian country within the borders of the State and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the Administrator of a revision to Mississippi's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Mississippi's SIP.

(4) Notwithstanding the provisions of paragraph (a)(3) of this section, if, at the time of the approval of Mississippi's SIP revision described in paragraph (a)(3) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(5) Notwithstanding the provisions of paragraph (a)(2) of this section, after 2022 the provisions of § 97.826(c) of this chapter (concerning the transfer of

CSAPR NO_X Ozone Season Group 2 allowances between certain accounts under common control), the provisions of § 97.826(e) of this chapter (concerning the conversion of amounts of unused CSAPR NO_X Ozone Season Group 2 allowances allocated for control periods before 2023 to different amounts of CSAPR NO_X Ozone Season Group 3 allowances), and the provisions of § 97.811(e) of this chapter (concerning the recall of CSAPR NO_X Ozone Season Group 2 allowances equivalent in quantity and usability to all such allowances allocated to units in the State and Indian country within the borders of the State for control periods after 2022) shall continue to apply.

(b) The owner and operator of each source located in the State of Mississippi and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart AA—Missouri

■ 17. Amend § 52.1326 by revising paragraph (b)(2) and (3) and adding paragraphs (b)(4) and (5) and (c) to read as follows:

§ 52.1326 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(b) * * *

(2) The owner and operator of each source and each unit located in the State of Missouri and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 2 Trading Program in subpart EEEEE of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2017 through 2022. The obligation to comply with such requirements will be eliminated by the promulgation of an approval by the Administrator of a revision to Missouri's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(ii), except to the extent the Administrator's approval is partial or conditional.

(3) The owner and operator of each source and each unit located in the State of Missouri and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements will be eliminated by the promulgation of an approval by the Administrator of a revision to Missouri's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii), except to the extent the Administrator's approval is partial or conditional.

(4) Notwithstanding the provisions of paragraphs (b)(2) and (3) of this section, if, at the time of the approval of Missouri's SIP revision described in paragraph (b)(2) or (3) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 2 allowances or CSAPR NO_X Ozone Season Group 3 allowances under subpart EEEEE or GGGGG, respectively, of part 97 of this chapter to units in the State for a control period in any year, the provisions of such subpart authorizing the Administrator to complete the allocation and recordation of such allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(5) Notwithstanding the provisions of paragraph (b)(2) of this section, after 2022 the provisions of § 97.826(c) of this chapter (concerning the transfer of CSAPR NO_X Ozone Season Group 2 allowances between certain accounts under common control), the provisions of § 97.826(e) of this chapter (concerning the conversion of amounts of unused CSAPR NO_X Ozone Season Group 2 allowances allocated for control periods before 2023 to different amounts of CSAPR NO_X Ozone Season Group 3 allowances), and the provisions of § 97.811(e) of this chapter (concerning the recall of CSAPR NO_X Ozone Season Group 2 allowances equivalent in quantity and usability to all such allowances allocated to units in the State for control periods after 2022) shall continue to apply.

(c) The owner and operator of each source located in the State of Missouri and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart DD—Nevada

■ 18. Add § 52.1492 to read as follows:

§ 52.1492 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

(a)(1) The owner and operator of each source and each unit located in the State of Nevada and Indian country within the borders of the State and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the Administrator of a revision to Nevada's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Nevada's SIP.

(2) Notwithstanding the provisions of paragraph (a)(1) of this section, if, at the time of the approval of Nevada's SIP revision described in paragraph (a)(1) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(b) The owner and operator of each source located in the State of Nevada and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart FF—New Jersey

■ 19. Amend § 52.1584 by:
■ a. In paragraph (e)(3), removing ''(b)(2)(v), except'' and adding in its place ''(b)(2)(iii), except''; and
■ b. Adding paragraph (f).

The addition reads as follows:

§ 52.1584 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(f) The owner and operator of each source located in the State of New Jersey and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart HH—New York

■ 20. Amend § 52.1684 by:
■ a. In paragraph (b)(3), revising the second and third sentences;
■ b. Revising paragraph (b)(4);
■ c. In paragraph (b)(5), adding ''and Indian country within the borders of the State'' after ''in the State''; and
■ d. Adding paragraph (c).

The revision and addition read as follows:

§ 52.1684 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(b) * * *

(3) * * * The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the Administrator of a revision to New York's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and(b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to New York's SIP.

(4) Notwithstanding the provisions of paragraph (b)(3) of this section, if, at the time of the approval of New York's SIP revision described in paragraph (b)(3) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

* * * * *

(c) The owner and operator of each source located in the State of New York and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart KK—Ohio

■ 21. Amend § 52.1882 by:
■ a. In paragraph (b)(3), removing ''(b)(2)(v), except'' and adding in its place ''(b)(2)(iii), except''; and
■ b. Adding paragraph (c).

The addition reads as follows:

§ 52.1882 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(c) The owner and operator of each source located in the State of Ohio and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart LL—Oklahoma

■ 22. Amend § 52.1930 by:
■ a. Redesignating paragraphs (a) through (c) as paragraphs (a)(1) through (3);
■ b. In newly redesignated paragraph (a)(2), removing ''2017 and each subsequent year.'' and adding in its place ''2017 through 2022.'', and removing the second and third sentences;
■ c. Revising newly redesignated paragraph (a)(3); and
■ c. Adding paragraphs (a)(4) and (5) and (b).

The revision and additions read as follows:

§ 52.1930 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

(a) * * *

(3) The owner and operator of each source and each unit located in the State of Oklahoma and Indian country within the borders of the State and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the Administrator of a revision to Oklahoma's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Oklahoma's SIP.

(4) Notwithstanding the provisions of paragraph (a)(3) of this section, if, at the time of the approval of Oklahoma's SIP revision described in paragraph (a)(3) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(5) Notwithstanding the provisions of paragraph (a)(2) of this section, after 2022 the provisions of § 97.826(c) of this chapter (concerning the transfer of CSAPR NO_X Ozone Season Group 2 allowances between certain accounts under common control), the provisions of § 97.826(e) of this chapter (concerning the conversion of amounts

of unused CSAPR NO_X Ozone Season Group 2 allowances allocated for control periods before 2023 to different amounts of CSAPR NO_X Ozone Season Group 3 allowances), and the provisions of § 97.811(e) of this chapter (concerning the recall of CSAPR NO_X Ozone Season Group 2 allowances equivalent in quantity and usability to all such allowances allocated to units in the State and Indian country within the borders of the State for control periods after 2022) shall continue to apply.

(b) The owner and operator of each source located in the State of Oklahoma and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart NN—Pennsylvania

■ 23. Amend § 52.2040 by:

■ a. In paragraph (b)(3), removing ''(b)(2)(v), except'' and adding in its place ''(b)(2)(iii), except''; and

■ b. Adding paragraph (c).

The addition reads as follows:

§ 52.2040 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(c) The owner and operator of each source located in the State of Pennsylvania and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart RR—Tennessee

■ 24. Amend § 52.2240 by:

■ a. In paragraph (e)(2), removing ''2017 and each subsequent year.'' and adding in its place ''2017 through 2022.'', and removing the second sentence;

■ b. Revising paragraph (e)(3); and

■ c. Adding paragraphs (e)(4) and (5).

The revision and additions read as follows:

§ 52.2240 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(e) * * *

(3) The owner and operator of each source and each unit located in the State of Tennessee and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements will be eliminated by the promulgation of an approval by the Administrator of a revision to Tennessee's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii), except to the extent the Administrator's approval is partial or conditional.

(4) Notwithstanding the provisions of paragraph (e)(3) of this section, if, at the time of the approval of Tennessee's SIP revision described in paragraph (e)(3) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(5) Notwithstanding the provisions of paragraph (e)(2) of this section, after 2022 the provisions of § 97.826(c) of this chapter (concerning the transfer of CSAPR NO_X Ozone Season Group 2 allowances between certain accounts under common control), the provisions of § 97.826(e) of this chapter (concerning the conversion of amounts of unused CSAPR NO_X Ozone Season Group 2 allowances allocated for control periods before 2023 to different amounts of CSAPR NO_X Ozone Season Group 3 allowances), and the provisions of § 97.811(e) of this chapter (concerning the recall of CSAPR NO_X Ozone Season Group 2 allowances equivalent in quantity and usability to all such allowances allocated to units in the State for control periods after 2022) shall continue to apply.

Subpart SS—Texas

■ 25. Amend § 52.2283 by:

■ a. In paragraph (d)(2), removing ''2017 and each subsequent year.'' and adding in its place ''2017 through 2022.'', and removing the second and third sentences;

■ b. Revising paragraph (d)(3); and

■ c. Adding paragraphs (d)(4) and (5) and (e).

The revision and additions read as follows:

§ 52.2283 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(d) * * *

(3) The owner and operator of each source and each unit located in the State of Texas and Indian country within the borders of the State and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the Administrator of a revision to Texas' State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Texas' SIP.

(4) Notwithstanding the provisions of paragraph (d)(3) of this section, if, at the time of the approval of Texas' SIP revision described in paragraph (d)(3) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(5) Notwithstanding the provisions of paragraph (d)(2) of this section, after 2022 the provisions of § 97.826(c) of this chapter (concerning the transfer of CSAPR NO_X Ozone Season Group 2 allowances between certain accounts under common control), the provisions of § 97.826(e) of this chapter

(concerning the conversion of amounts of unused CSAPR NO_X Ozone Season Group 2 allowances allocated for control periods before 2023 to different amounts of CSAPR NO_X Ozone Season Group 3 allowances), and the provisions of § 97.811(e) of this chapter (concerning the recall of CSAPR NO_X Ozone Season Group 2 allowances equivalent in quantity and usability to all such allowances allocated to units in the State and Indian country within the borders of the State for control periods after 2022) shall continue to apply.

(e) The owner and operator of each source located in the State of Texas and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart TT—Utah

■ 26. Add § 52.2356 to read as follows:

§ 52.2356 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

(a)(1) The owner and operator of each source and each unit located in the State of Utah and Indian country within the borders of the State and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the Administrator of a revision to Utah's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Utah's SIP.

(2) Notwithstanding the provisions of paragraph (a)(1) of this section, if, at the time of the approval of Utah's SIP revision described in paragraph (a)(1) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(b) The owner and operator of each source located in the State of Utah and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart VV—Virginia

■ 27. Amend § 52.2440 by:

■ a. In paragraph (b)(3), removing ''(b)(2)(v), except'' and adding in its place ''(b)(2)(iii), except''; and

■ b. Adding paragraph (c).

The addition reads as follows:

§ 52.2440 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(c) The owner and operator of each source located in the State of Virginia and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart XX—West Virginia

■ 28. Amend § 52.2540 by:

■ a. In paragraph (b)(3), removing ''(b)(2)(v), except'' and adding in its place ''(b)(2)(iii), except''; and

■ b. Adding paragraph (c).

The addition reads as follows:

§ 52.2540 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(c) The owner and operator of each source located in the State of West Virginia and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart YY—Wisconsin

■ 29. Amend § 52.2587 by:

■ a. In paragraph (e)(2), removing ''2017 and each subsequent year.'' and adding in its place ''2017 through 2022.'', and removing the second and third sentences;

■ b. Revising paragraph (e)(3); and

■ c. Adding paragraphs (e)(4) and (5) and (f).

The revision and additions read as follows:

§ 52.2587 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(e) * * *

(3) The owner and operator of each source and each unit located in the State of Wisconsin and Indian country within the borders of the State and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the Administrator of a revision to Wisconsin's State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Wisconsin's SIP.

(4) Notwithstanding the provisions of paragraph (e)(3) of this section, if, at the time of the approval of Wisconsin's SIP revision described in paragraph (e)(3) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of subpart

GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(5) Notwithstanding the provisions of paragraph (e)(2) of this section, after 2022 the provisions of § 97.826(c) of this chapter (concerning the transfer of CSAPR NO_X Ozone Season Group 2 allowances between certain accounts under common control), the provisions of § 97.826(e) of this chapter (concerning the conversion of amounts of unused CSAPR NO_X Ozone Season Group 2 allowances allocated for control periods before 2023 to different amounts of CSAPR NO_X Ozone Season Group 3 allowances), and the provisions of § 97.811(e) of this chapter (concerning the recall of CSAPR NO_X Ozone Season Group 2 allowances equivalent in quantity and usability to all such allowances allocated to units in the State and Indian country within the borders of the State for control periods after 2022) shall continue to apply.

(f) The owner and operator of each source located in the State of Wisconsin and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

Subpart ZZ—Wyoming

■ 30. Add § 52.2638 to read as follows:

§ 52.2638 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

(a)(1) The owner and operator of each source and each unit located in the State of Wyoming and Indian country within the borders of the State and for which requirements are set forth under the CSAPR NO_X Ozone Season Group 3 Trading Program in subpart GGGGG of part 97 of this chapter must comply with such requirements with regard to emissions occurring in 2023 and each subsequent year. The obligation to comply with such requirements with regard to sources and units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority will be eliminated by the promulgation of an approval by the Administrator of a revision to Wyoming State Implementation Plan (SIP) as correcting the SIP's deficiency that is the basis for the CSAPR Federal Implementation Plan (FIP) under § 52.38(b)(1) and (b)(2)(iii) for those sources and units, except to the extent the Administrator's approval is partial or conditional. The obligation to comply with such requirements with regard to sources and units located in areas of Indian country within the borders of the State not subject to the State's SIP authority will not be eliminated by the promulgation of an approval by the Administrator of a revision to Wyoming's SIP.

(2) Notwithstanding the provisions of paragraph (a)(1) of this section, if, at the time of the approval of Wyoming's SIP revision described in paragraph (a)(1) of this section, the Administrator has already started recording any allocations of CSAPR NO_X Ozone Season Group 3 allowances under subpart GGGGG of part 97 of this chapter to units in the State and areas of Indian country within the borders of the State subject to the State's SIP authority for a control period in any year, the provisions of subpart GGGGG of part 97 of this chapter authorizing the Administrator to complete the allocation and recordation of CSAPR NO_X Ozone Season Group 3 allowances to such units for each such control period shall continue to apply, unless provided otherwise by such approval of the State's SIP revision.

(b) The owner and operator of each source located in the State of Wyoming and Indian country within the borders of the State and for which requirements are set forth in § 52.40 and § 52.41, § 52.42, § 52.43, § 52.44, or § 52.45 must comply with such requirements with regard to emissions occurring in 2026 and each subsequent year.

PART 75—CONTINUOUS EMISSION MONITORING

■ 31. The authority citation for part 75 is revised to read as follows:

Authority: 42 U.S.C. 7401–7671q and 7651k note.

■ 32. Amend § 75.72 by:
■ a. In paragraph (c)(3), removing ''appendix B of this part.'' and adding in its place ''appendix B to this part.'';
■ b. In paragraph (e)(1)(ii), removing ''heat input from'' and adding in its place ''heat input rate to'';
■ c. In paragraph (e)(2), removing ''appendix D of this part'' and adding in its place ''appendix D to this part''; and
■ d. Adding paragraph (f).

The addition reads as follows:

§ 75.72 Determination of NO_X mass emissions for common stack and multiple stack configurations.

* * * * *

(f) *Procedures for apportioning hourly NO_X mass emission rate to the unit level.* If the owner or operator of a unit determining hourly NO_X mass emission rate at a common stack under this section is subject to a State or federal NO_X mass emissions reduction program under subpart GGGGG of part 97 of this chapter or under a state implementation plan approved pursuant to § 52.38(b)(12) of this chapter, then on and after January 1, 2024, the owner or operator shall apportion the hourly NO_X mass emissions rate at the common stack to each unit using the common stack based on the ratio of the hourly heat input rate for each such unit to the total hourly heat input rate for all such units, in conjunction with the appropriate unit and stack operating times, according to the procedures in section 8.5.3 of appendix F to this part.

* * * * *

■ 33. Amend § 75.73 by:
■ a. Revising paragraph (a)(3);
■ b. In paragraph (c)(1), removing ''No_X emissions'' and adding in its place ''NO_X emissions'';
■ c. Adding a paragraph heading to paragraph (c)(2);
■ d. Revising paragraphs (c)(3) and (f)(1) introductory text;
■ e. Removing and reserving paragraph (f)(1)(i)(B);
■ f. In paragraph (f)(1)(ii)(G), removing ''appendix D;'' and adding in its place ''appendix D to this part;'';
■ g. Adding paragraphs (f)(1)(ix) and (x);
■ h. Adding a paragraph heading to paragraph (f)(2); and
■ i. Revising paragraph (f)(4).

The revisions and addition reads as follows:

§ 75.73 Recordkeeping and reporting.

* * * * *

(a) * * *

(3) For each hour when the unit is operating, NO_X mass emission rate, calculated in accordance with section 8 of appendix F to this part.

* * * * *

(c) * * *

(2) *Monitoring plan updates.* * * *

(3) *Contents of the monitoring plan.* Each monitoring plan shall contain the information in § 75.53(g)(1) in electronic format and the information in § 75.53(g)(2) in hardcopy format. In addition, to the extent applicable, each monitoring plan shall contain the information in § 75.53(h)(1)(i) and (h)(2)(i) in electronic format and the information in § 75.53(h)(1)(ii) and (h)(2)(ii) in hardcopy format. For units using the low mass emissions excepted methodology under § 75.19, the monitoring plan shall include the additional information in § 75.53(h)(4)(i) and (h)(4)(ii). The monitoring plan also

shall include a seasonal controls indicator and an ozone season fuel-switching flag.

(f) * * *

(1) *Electronic submission.* The designated representative for an affected unit shall electronically report the data and information in this paragraph (f)(1) and in paragraphs (f)(2) and (3) of this section to the Administrator quarterly, unless the unit has been placed in long-term cold storage (as defined in § 72.2 of this chapter). Each electronic report must be submitted to the Administrator within 30 days following the end of each calendar quarter. Each electronic report shall include the information provided in paragraphs (f)(1)(i) through (x) of this section and shall also include the date of report generation. A unit placed into long-term cold storage is exempted from submitting quarterly reports beginning with the calendar quarter following the quarter in which the unit is placed into long-term cold storage, provided that the owner or operator shall submit quarterly reports for the unit beginning with the data from the quarter in which the unit recommences operation (where the initial quarterly report contains hourly data beginning with the first hour of recommenced operation of the unit).

* * * * *

(ix) On and after on January 1, 2024, for a unit subject to subpart GGGGG of part 97 of this chapter or a state implementation plan approved under § 52.38(b)(12) of this chapter and determining NO_X mass emission rate at a common stack, apportioned hourly NO_X mass emission rate for the unit, lb/hr.

(x) On and after January 1, 2024, for a unit subject to a backstop daily NO_X emission rate under subpart GGGGG of part 97 of this chapter or under a state implementation plan approved under § 52.38(b)(12) of this chapter:

(A) Daily NO_X emissions (lbs) for each day of the reporting period;

(B) Daily heat input (mmBtu) for each day of the reporting period;

(C) Daily average NO_X emission rate (lb/mmBtu, rounded to the nearest thousandth) for each day of the reporting period;

(D) Daily NO_X emissions (lbs) exceeding the applicable backstop daily NO_X emission rate for each day of the reporting period; and

(E) Cumulative NO_X emissions (tons, rounded to the nearest tenth) exceeding the applicable backstop daily NO_X emission rate during the ozone season.

(2) *Verification of identification codes and formulas.* * * *

* * * * *

(4) *Electronic format, method of submission, and explanatory information.* The designated representative shall comply with all of the quarterly reporting requirements in § 75.64(d), (f), and (g).

■ 34. Revise § 75.75 to read as follows:

§ 75.75 Additional ozone season calculation procedures.

(a) The owner or operator of a unit that is required to calculate daily or ozone season heat input shall do so by summing the unit's hourly heat input determined according to the procedures in this part for all hours in which the unit operated during the day or ozone season.

(b) The owner or operator of a unit that is required to determine daily or ozone season NO_X emission rate (in lbs/mmBtu) shall do so by dividing daily or ozone season NO_X mass emissions (in lbs) determined in accordance with this subpart, by daily or ozone season heat input determined in accordance with paragraph (a) of this section.

■ 35. Amend appendix F to part 75 by:

■ a. Adding section 5.3.3;

■ b. In section 8.1.2, revising the introductory text preceding Equation F–25;

■ c. In section 8.4, revising the introductory text, paragraph (a) introductory text (preceding Equation F–27), and paragraph (b) introductory text (preceding Equation F–27a), and adding paragraph (c);

■ d. In section 8.5.2, removing ''the hourly NO_X mass emissions at each unit'' and adding in its place ''hourly NO_X mass emissions at the common stack.''; and

■ e. Adding section 8.5.3.

The additions and revisions read as follows

Appendix F to Part 75—Conversion Procedures

* * * * *

5.3.3 Calculate total daily heat input for a unit using a flow monitor and diluent monitor to calculate heat input, using the following equation:

$$HI_d = \sum_{h=1}^{24} HI_h t_h \quad \text{(Eq. F-18c)}$$

Where:

HI_d = Total heat input for a unit for the day, mmBtu.

HI_h = Heat input rate for the unit for hour ''h'' from Equation F–15, F–16, F–17, F–18, F–21a, or F–21b, mmBtu/hr.

t_h = Unit operating time, fraction of the hour (0.00 to 1.00, in equal increments from one hundredth to one quarter of an hour, at the option of the owner or operator).

h = Designation of a particular hour.

* * * * *

8.1.2 If NO_X emission rate is measured at a common stack and heat input rate is measured at the unit level, calculate the hourly heat input rate at the common stack according to the following formula:

* * * * *

8.4 Use the following equations to calculate daily, quarterly, cumulative ozone season, and cumulative year-to-date NO_X mass emissions:

(a) When hourly NO_X mass emissions are reported in lb., use Eq. F–27 to calculate quarterly, cumulative ozone season, and cumulative year-to-date NO_X mass emissions in tons. * * *

(b) When hourly NO_X mass emission rate is reported in lb/hr, use Eq. F–27a to calculate quarterly, cumulative ozone season, and cumulative year-to-date NO_X mass emissions in tons. * * *

(c) To calculate daily NO_X mass emissions for a unit in pounds, use Eq. F–27b.

$$M_{(NOX)_d} = \sum_{h=1}^{24} E_{(NOX)_h} t_h$$

(Eq. F-27b)

Where:

$M_{(NOX)_d}$ = NO_X mass emissions for a unit for the day, pounds.
$E_{(NOX)_h}$ = NO_X mass emission rate for the unit for hour "h" from Equation F–24a, F–26a, F–26b, or F–28, lb/hr.
t_h = Unit operating time, fraction of the hour (0.00 to 1.00, in equal increments from one hundredth to one quarter of an hour, at the option of the owner or operator).
h = Designation of a particular hour.

* * * * *

8.5.3 Where applicable, the owner or operator of a unit that determines hourly NO_X mass emission rate at a common stack shall apportion hourly NO_X mass emissions rate to the units using the common stack based on the hourly heat input rate, using Equation F–28:

$$E_{(NOX)_i} = E_{(NOX)_{CS}} \left(\frac{t_{CS}}{t_i}\right)\left[\frac{HI_i t_i}{\sum_{i=1}^{n} HI_i t_i}\right]$$

(Eq. F-28)

Where:

$E_{(NOX)_i}$ = Apportioned NO_X mass emission rate for unit "i", lb/hr.
$E_{(NOX)_{CS}}$ = NO_X mass emission rate at the common stack, lb/hr.
HI_i = Heat input rate for unit "i", mmBtu/hr.
t_i = Operating time for unit "i", fraction of the hour (0.00 to 1.00, in equal increments from one hundredth to one quarter of an hour, at the option of the owner or operator).
t_{CS} = Common stack operating time, fraction of the hour (0.00 to 1.00, in equal increments from one hundredth to one quarter of an hour, at the option of the owner or operator).
n = Number of units using the common stack.
i = Designation of a particular unit.

PART 78—APPEAL PROCEDURES

■ 36. The authority citation for part 78 continues to read as follows:

Authority: 42 U.S.C. 7401–7671q.

■ 37. Amend § 78.1 by:
■ a. In paragraph (b)(17)(viii), adding "or (e)" after "§ 97.826(d)";
■ b. In paragraph (b)(17)(ix), adding "or (e)" after "§ 97.811(d)"; and
■ c. Revising paragraph (b)(19).

The revision reads as follows:

§ 78.1 Purpose and scope.

* * * * *

(b) * * *

(19) Under subpart GGGGG of part 97 of this chapter,

(i) The decision on the calculation of a state CSAPR NO_X Ozone Season Group 3 trading budget under § 97.1010(a)(3) of this chapter.

(ii) The decision on the allocation of CSAPR NO_X Ozone Season Group 3 allowances under § 97.1011 or § 97.1012 of this chapter.

(iii) The decision on the transfer of CSAPR NO_X Ozone Season Group 3 allowances under § 97.1023 of this chapter.

(iv) The decision on the deduction of CSAPR NO_X Ozone Season Group 3 allowances under § 97.1024, § 97.1025, or § 97.1026(d) of this chapter.

(v) The correction of an error in an Allowance Management System account under § 97.1027 of this chapter.

(vi) The adjustment of information in a submission and the decision on the deduction and transfer of CSAPR NO_X Ozone Season Group 3 allowances based on the information as adjusted under § 97.1028 of this chapter.

(vii) The finalization of control period emissions data, including retroactive adjustment based on audit.

(viii) The approval or disapproval of a petition under § 97.1035 of this chapter.

* * * * *

PART 97—FEDERAL NO_X BUDGET TRADING PROGRAM, CAIR NO_X AND SO_2 TRADING PROGRAMS, CSAPR NO_X AND SO_2 TRADING PROGRAMS, AND TEXAS SO_2 TRADING PROGRAM

■ 38. The authority citation for part 97 continues to read as follows:

Authority: 42 U.S.C. 7401, 7403, 7410, 7426, 7491, 7601, and 7651, *et seq.*

Subpart AAAAA—CSAPR NO_X Annual Trading Program

§ 97.402 [Amended]

■ 39. Amend § 97.402 by:
■ a. In the definition of "CSAPR NO_X Ozone Season Group 1 Trading Program", removing "(b)(2)(i) and (ii), and" and adding in its place "(b)(2)(i), and";
■ b. In the definition of "CSAPR NO_X Ozone Season Group 2 Trading Program", removing "(b)(2)(iii) and (iv), and" and adding in its place "(b)(2)(ii), and"; and
■ c. In the definition of "CSAPR NO_X Ozone Season Group 3 Trading Program", removing "(b)(2)(v), and" and adding in its place "(b)(2)(iii), and";

§ 97.411 [Amended]

■ 40. Amend § 97.411 by:
■ a. In paragraphs (b)(1)(i)(A) and (B), removing "State, in accordance" and adding in its place "State and areas of Indian country within the borders of the State subject to the State's SIP authority, in accordance"; and
■ b. In paragraphs (b)(2)(i)(A) and (B), removing "Indian country within the borders of a State, in accordance" and adding in its place "areas of Indian country within the borders of a State not subject to the State's SIP authority, in accordance".

§ 97.412 [Amended]

■ 41. Amend § 97.412 by:
■ a. In paragraph (a) introductory text, removing "State, the Administrator" and adding in its place "State and areas of Indian country within the borders of the State subject to the State's SIP authority, the Administrator";
■ b. In paragraphs (a)(3)(iii) and (a)(5), adding "and areas of Indian country within the borders of the State subject to the State's SIP authority" after "in the State";
■ c. In paragraph (a)(10), removing "State, is allocated" and adding in its place "State and areas of Indian country

within the borders of the State subject to the State's SIP authority, is allocated'';

■ d. In paragraph (b) introductory text, removing ''Indian country within the borders of each State, the Administrator'' and adding in its place ''areas of Indian country within the borders of each State not subject to the State's SIP authority, the Administrator''; and

■ e. In paragraph (b)(5), removing ''Indian country within the borders of the State'' and adding in its place ''areas of Indian country within the borders of the State not subject to the State's SIP authority''.

§ 97.421 [Amended]

■ 42. In § 97.421, amend paragraph (f)(2) by removing ''2022'' and adding in its place ''2024'', and removing ''third'' before ''year after the year''.

§ 97.426 [Amended]

■ 43. In § 97.426, amend paragraph (c) by removing ''State (or Indian'' and adding in its place ''State (and Indian''.

Subpart BBBBB—CSAPR NO_X Ozone Season Group 1 Trading Program

§ 97.502 [Amended]

■ 44. Amend § 97.502 by:

■ a. In the definition of ''CSAPR NO_X Ozone Season Group 1 Trading Program'', removing ''(b)(2)(i) and (ii), and'' and adding in its place ''(b)(2)(i), and'';

■ b. In the definition of ''CSAPR NO_X Ozone Season Group 2 Trading Program'', removing ''(b)(2)(iii) and (iv), and'' and adding in its place ''(b)(2)(ii), and'';

■ c. In the definition of ''CSAPR NO_X Ozone Season Group 3 allowance'', adding ''or (e)'' after ''§ 97.826(d)'', and adding ''or less'' after ''one ton'';

■ d. In the definition of ''CSAPR NO_X Ozone Season Group 3 Trading Program'', removing ''(b)(2)(v), and'' and adding in its place ''(b)(2)(iii), and''; and

■ e. In the definition of ''State'', removing ''(b)(2)(i) and (ii), and'' and adding in its place ''(b)(2)(i), and''.

§ 97.511 [Amended]

■ 45. Amend § 97.511 by:

■ a. In paragraphs (b)(1)(i)(A) and (B), removing ''State, in accordance'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, in accordance''; and

■ b. In paragraphs (b)(2)(i)(A) and (B), removing ''Indian country within the borders of a State, in accordance'' and adding in its place ''areas of Indian country within the borders of a State not subject to the State's SIP authority, in accordance''.

§ 97.512 [Amended]

■ 46. Amend § 97.512 by:

■ a. In paragraph (a) introductory text, removing ''State, the Administrator'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, the Administrator'';

■ b. In paragraphs (a)(3)(iii) and (a)(5), adding ''and areas of Indian country within the borders of the State subject to the State's SIP authority'' after ''in the State'';

■ c. In paragraph (a)(10), removing ''State, is allocated'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, is allocated'';

■ d. In paragraph (b) introductory text, removing ''Indian country within the borders of each State, the Administrator'' and adding in its place ''areas of Indian country within the borders of each State not subject to the State's SIP authority, the Administrator''; and

■ e. In paragraph (b)(5), removing ''Indian country within the borders of the State'' and adding in its place ''areas of Indian country within the borders of the State not subject to the State's SIP authority''.

§ 97.521 [Amended]

■ 47. In § 97.521, amend paragraph (f)(2) by removing ''2022'' and adding in its place ''2024'', and removing ''third'' before ''year after the year''.

■ 48. Amend § 97.526 by:

■ a. In paragraph (c), removing ''State (or Indian'' and adding in its place ''State (and Indian'';

■ b. In paragraph (d)(1) introductory text, removing ''§ 52.38(b)(2)(i) of this chapter (or'' and adding in its place ''§ 52.38(b)(2)(i)(A) of this chapter (and'';

■ c. In paragraph (d)(1)(ii), removing ''except a State listed in § 52.38(b)(2)(i)'' and adding in its place ''listed in § 52.38(b)(2)(ii)'';

■ d. In paragraph (d)(1)(iv), removing ''§ 52.38(b)(2)(iii) or (iv) of this chapter (or'' and adding in its place ''§ 52.38(b)(2)(ii) of this chapter (and'';

■ e. Revising paragraph (d)(2)(i);

■ f. In paragraph (d)(2)(ii), removing ''§ 52.38(b)(2)(v) of this chapter (or'' and adding in its place ''§ 52.38(b)(2)(iii)(A) of this chapter (and'';

■ g. Adding paragraph (d)(2)(iii);

■ h. In paragraph (e)(1), removing ''chapter (or Indian'' and adding in its place ''chapter (and Indian'';

■ i. In paragraph (e)(2), removing ''§ 52.38(b)(2)(iv) of this chapter (or'' and adding in its place ''§ 52.38(b)(2)(iii)(A) of this chapter (and''; and

■ j. Adding paragraph (e)(3).

The revisions and additions read as follows:

§ 97.526 Banking and conversion.

* * * * *

(d) * * *

(2)(i) Except as provided in paragraphs (d)(2)(ii) and (iii) of this section, after the Administrator has carried out the procedures set forth in paragraph (d)(1) of this section, upon any determination that would otherwise result in the initial recordation of a given number of CSAPR NO_X Ozone Season Group 1 allowances in the compliance account for a source in a State listed in § 52.38(b)(2)(ii) of this chapter (and Indian country within the borders of such a State), the Administrator will not record such CSAPR NO_X Ozone Season Group 1 allowances but instead will allocate and record in such account an amount of CSAPR NO_X Ozone Season Group 2 allowances for the control period in 2017 computed as the quotient, rounded up to the nearest allowance, of such given number of CSAPR NO_X Ozone Season Group 1 allowances divided by the conversion factor determined under paragraph (d)(1)(ii) of this section.

* * * * *

(iii) After the Administrator has carried out the procedures set forth in paragraph (d)(1) of this section and § 97.826(e)(1), upon any determination that would otherwise result in the initial recordation of a given number of CSAPR NO_X Ozone Season Group 1 allowances in the compliance account for a source in a State listed in § 52.38(b)(2)(iii)(B) of this chapter (and Indian country within the borders of such a State), the Administrator will not record such CSAPR NO_X Ozone Season Group 1 allowances but instead will allocate and record in such account an amount of CSAPR NO_X Ozone Season Group 3 allowances for the control period in 2023 computed as the quotient, rounded up to the nearest allowance, of such given number of CSAPR NO_X Ozone Season Group 1 allowances divided by the conversion factor determined under paragraph (d)(1)(ii) of this section and further divided by the conversion factor determined under § 97.826(e)(1)(ii).

* * * * *

(e) * * *

(3) After the Administrator has carried out the procedures set forth in paragraph (d)(1) of this section and § 97.826(e)(1), the owner or operator of a CSAPR NO_X Ozone Season Group 1

source in a State listed in § 52.38(b)(2)(iii)(B) of this chapter (and Indian country within the borders of such a State) may satisfy a requirement to hold a given number of CSAPR NO_X Ozone Season Group 1 allowances for the control period in 2015 or 2016 by holding instead, in a general account established for this sole purpose, an amount of CSAPR NO_X Ozone Season Group 3 allowances for the control period in 2023 (or any later control period for which the allowance transfer deadline defined in § 97.1002 has passed) computed as the quotient, rounded up to the nearest allowance, of such given number of CSAPR NO_X Ozone Season Group 1 allowances divided by the conversion factor determined under paragraph (d)(1)(ii) of this section and further divided by the conversion factor determined under § 97.826(e)(1)(ii).

Subpart CCCCC—CSAPR SO_2 Group 1 Trading Program

§ 97.602 [Amended]

■ 49. Amend § 97.602 by:

■ a. In the definition of ''CSAPR NO_X Ozone Season Group 1 Trading Program'', removing ''(b)(2)(i) and (ii), and'' and adding in its place ''(b)(2)(i), and'';

■ b. In the definition of ''CSAPR NO_X Ozone Season Group 2 Trading Program'', removing ''(b)(2)(iii) and (iv), and'' and adding in its place ''(b)(2)(ii), and'';

■ c. In the definition of ''CSAPR NO_X Ozone Season Group 3 Trading Program'', removing ''(b)(2)(v), and'' and adding in its place ''(b)(2)(iii), and'';

§ 97.611 [Amended]

■ 50. Amend § 97.611 by:

■ a. In paragraphs (b)(1)(i)(A) and (B), removing ''State, in accordance'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, in accordance''; and

■ b. In paragraphs (b)(2)(i)(A) and (B), removing ''Indian country within the borders of a State, in accordance'' and adding in its place ''areas of Indian country within the borders of a State not subject to the State's SIP authority, in accordance''.

§ 97.612 [Amended]

■ 51. Amend § 97.612 by:

■ a. In paragraph (a) introductory text, removing ''State, the Administrator'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, the Administrator'';

■ b. In paragraphs (a)(3)(iii) and (a)(5), adding ''and areas of Indian country within the borders of the State subject to the State's SIP authority'' after ''in the State'';

■ c. In paragraph (a)(10), removing ''State, is allocated'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, is allocated'';

■ d. In paragraph (b) introductory text, removing ''Indian country within the borders of each State, the Administrator'' and adding in its place ''areas of Indian country within the borders of each State not subject to the State's SIP authority, the Administrator''; and

■ e. In paragraph (b)(5), removing ''Indian country within the borders of the State'' and adding in its place ''areas of Indian country within the borders of the State not subject to the State's SIP authority''.

§ 97.621 [Amended]

■ 52. In § 97.621, amend paragraph (f)(2) by removing ''2022'' and adding in its place ''2024'', and removing ''third'' before ''year after the year''.

§ 97.626 [Amended]

■ 53. In § 97.626, amend paragraph (c) by removing ''State (or Indian'' and adding in its place ''State (and Indian''.

Subpart DDDDD—CSAPR SO_2 Group 2 Trading Program

■ 54. Amend § 97.702 by:

■ a. In the definition of ''alternate designated representative'', removing ''or CSAPR NO_X Ozone Season Group 2 Trading Program, then'' and adding in its place ''CSAPR NO_X Ozone Season Group 2 Trading Program, or CSAPR NO_X Ozone Season Group 3 Trading Program, then'';

■ b. In the definition of ''CSAPR NO_X Ozone Season Group 1 Trading Program'', removing ''(b)(2)(i) and (ii), and'' and adding in its place ''(b)(2)(i), and'';

■ c. In the definition of ''CSAPR NO_X Ozone Season Group 2 Trading Program'', removing ''(b)(2)(iii) and (iv), and'' and adding in its place ''(b)(2)(ii), and'';

■ d. Adding in alphabetical order a definition for ''CSAPR NO_X Ozone Season Group 3 Trading Program''; and

■ e. In the definition of ''designated representative'', removing ''or CSAPR NO_X Ozone Season Group 2 Trading Program, then'' and adding in its place ''CSAPR NO_X Ozone Season Group 2 Trading Program, or CSAPR NO_X Ozone Season Group 3 Trading Program, then''.

§ 97.702 Definitions.

* * * * *

CSAPR NO_X Ozone Season Group 3 Trading Program means a multi-state NO_X air pollution control and emission reduction program established in accordance with subpart GGGGG of this part and § 52.38(b)(1), (b)(2)(iii), and (b)(10) through (14) and (17) of this chapter (including such a program that is revised in a SIP revision approved by the Administrator under § 52.38(b)(10) or (11) of this chapter or that is established in a SIP revision approved by the Administrator under § 52.38(b)(12) of this chapter), as a means of mitigating interstate transport of ozone and NO_X.

* * * * *

§ 97.711 [Amended]

■ 55. Amend § 97.711 by:

■ a. In paragraphs (b)(1)(i)(A) and (B), removing ''State, in accordance'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, in accordance''; and

■ b. In paragraphs (b)(2)(i)(A) and (B), removing ''Indian country within the borders of a State, in accordance'' and adding in its place ''areas of Indian country within the borders of a State not subject to the State's SIP authority, in accordance''.

§ 97.712 [Amended]

■ 56. Amend § 97.712 by:

■ a. In paragraph (a) introductory text, removing ''State, the Administrator'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, the Administrator'';

■ b. In paragraphs (a)(3)(iii) and (a)(5), adding ''and areas of Indian country within the borders of the State subject to the State's SIP authority'' after ''in the State'';

■ c. In paragraph (a)(10), removing ''State, is allocated'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, is allocated'';

■ d. In paragraph (b) introductory text, removing ''Indian country within the borders of each State, the Administrator'' and adding in its place ''areas of Indian country within the borders of each State not subject to the State's SIP authority, the Administrator''; and

■ e. In paragraph (b)(5), removing ''Indian country within the borders of the State'' and adding in its place ''areas of Indian country within the borders of the State not subject to the State's SIP authority''.

§ 97.721 [Amended]

■ 57. In § 97.721, amend paragraph (f)(2) by removing ''2022'' and adding in its place ''2024'', and removing ''third'' before ''year after the year''.

§ 97.726 [Amended]

■ 58. In § 97.726, amend paragraph (c) by removing ''State (or Indian'' and adding in its place ''State (and Indian''.

§ 97.734 [Amended]

■ 59. In § 97.734, amend paragraph (d)(3) by removing ''or CSAPR NO_X Ozone Season Group 2 Trading Program, quarterly'' and adding in its place ''CSAPR NO_X Ozone Season Group 2 Trading Program, or CSAPR NO_X Ozone Season Group 3 Trading Program, quarterly''.

Subpart EEEEE—CSAPR NO_X Ozone Season Group 2 Trading Program

■ 60. Amend § 97.802 by:

■ a. In the definition of ''assurance account'', removing ''base CSAPR'' and adding in its place ''CSAPR'';

■ b. Removing the definitions for ''base CSAPR NO_X Ozone Season Group 2 source'' and ''base CSAPR NO_X Ozone Season Group 2 unit'';

■ c. In the definition of ''common designated representative'', removing ''base CSAPR'' and adding in its place ''CSAPR'';

■ d. In the definition of ''common designated representative's assurance level'', revising paragraph (1);

■ e. In the definition of ''common designated representative's share'', removing ''base CSAPR'' and adding in its place ''CSAPR'' each time it appears;

■ f. In the definition of ''CSAPR NO_X Ozone Season Group 2 Trading Program'', removing ''(b)(2)(iii) and (iv), and'' and adding in its place ''(b)(2)(ii), and'';

■ g. In the definition of ''CSAPR NO_X Ozone Season Group 3 allowance'', adding ''or (e)'' after ''§ 97.826(d)'', and adding ''or less'' after ''one ton'';

■ h. In the definition of ''CSAPR NO_X Ozone Season Group 3 Trading Program'', removing ''(b)(2)(v), and'' and adding in its place ''(b)(2)(iii), and''; and

■ i. In the definition of ''State'', removing ''(b)(2)(iii) and (iv), and'' and adding in its place ''(b)(2)(ii), and''.

The revision reads as follows:

§ 97.802 Definitions.

* * * * *

Common designated representative's assurance level * * *

(1) The amount (rounded to the nearest allowance) equal to the sum of the total amount of CSAPR NO_X Ozone Season Group 2 allowances allocated for such control period to the group of one or more CSAPR NO_X Ozone Season Group 2 units in such State (and such Indian country) having the common designated representative for such control period and the total amount of CSAPR NO_X Ozone Season Group 2 allowances purchased by an owner or operator of such CSAPR NO_X Ozone Season Group 2 units in an auction for such control period and submitted by the State or the permitting authority to the Administrator for recordation in the compliance accounts for such CSAPR NO_X Ozone Season Group 2 units in accordance with the CSAPR NO_X Ozone Season Group 2 allowance auction provisions in a SIP revision approved by the Administrator under § 52.38(b)(8) or (9) of this chapter, multiplied by the sum of the State NO_X Ozone Season Group 2 trading budget under § 97.810(a) and the State's variability limit under § 97.810(b) for such control period, and divided by such State NO_X Ozone Season Group 2 trading budget;

* * * * *

§ 97.806 [Amended]

■ 61. In § 97.806, amend paragraphs (c)(2)(i) introductory text, (c)(2)(i)(B), (c)(2)(iii) and (iv), and (c)(3)(ii) by removing ''base CSAPR'' and adding in its place ''CSAPR'' each time it appears.

§ 97.810 [Amended]

■ 62. In § 97.810, amend paragraphs (a)(1)(i) through (iii), (a)(2)(i) and (ii), (a)(12)(i) through (iii), (a)(13)(i) and (ii), (a)(17)(i) through (iii), (a)(19)(i) and (ii), (a)(20)(i) through (iii), (a)(23)(i) through (iii), and (b)(1), (2), (12), (13), (17), (19), (20), and (23) by removing ''and thereafter'' and adding in its place ''through 2022''.

■ 63. Amend § 97.811 by:

■ a. In paragraphs (b)(1)(i)(A) and (B), removing ''State, in accordance'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, in accordance'';

■ b. In paragraphs (b)(2)(i)(A) and (B), removing ''Indian country within the borders of a State, in accordance'' and adding in its place ''areas of Indian country within the borders of a State not subject to the State's SIP authority, in accordance'';

■ c. In paragraph (d)(1), removing ''§ 52.38(b)(2)(iv) of this chapter (or'' and adding in its place ''§ 52.38(b)(2)(ii)(B) of this chapter (and''; and

■ d. Adding paragraph (e).

The addition reads as follows:

§ 97.811 Timing requirements for CSAPR NO_X Ozone Season Group 2 allowance allocations.

* * * * *

(e) *Recall of CSAPR NO_X Ozone Season Group 2 allowances allocated for control periods after 2022.* (1) Notwithstanding any other provision of this subpart, part 52 of this chapter, or any SIP revision approved under § 52.38(b) of this chapter, the provisions of this paragraph and paragraphs (e)(2) through (7) of this section shall apply with regard to each CSAPR NO_X Ozone Season Group 2 allowance that was allocated for a control period after 2022 to any unit (including a permanently retired unit qualifying for an exemption under § 97.805) in a State listed in § 52.38(b)(2)(ii)(C) of this chapter (and Indian country within the borders of such a State) and that was initially recorded in the compliance account for the source that includes the unit, whether such CSAPR NO_X Ozone Season Group 2 allowance was allocated pursuant to this subpart or pursuant to a SIP revision approved under § 52.38(b) of this chapter and whether such CSAPR NO_X Ozone Season Group 2 allowance remains in such compliance account or has been transferred to another Allowance Management System account.

(2)(i) For each CSAPR NO_X Ozone Season Group 2 allowance described in paragraph (e)(1) of this section that was allocated for a given control period and initially recorded in a given source's compliance account, one CSAPR NO_X Ozone Season Group 2 allowance that was allocated for the same or an earlier control period and initially recorded in the same or any other Allowance Management System account must be surrendered in accordance with the procedures in paragraphs (e)(3) and (4) of this section.

(ii)(A) The surrender requirement under paragraph (e)(2)(i) of this section corresponding to each CSAPR NO_X Ozone Season Group 2 allowance described in paragraph (e)(1) of this section initially recorded in a given source's compliance account shall apply to such source's current owners and operators, except as provided in paragraph (e)(2)(ii)(B) of this section.

(B) If the owners and operators of a given source as of a given date assumed ownership and operational control of the source through a transaction that did not also provide rights to direct the use or transfer of a given CSAPR NO_X Ozone Season Group 2 allowance described in paragraph (e)(1) of this section with regard to such source (whether recordation of such CSAPR NO_X Ozone Season Group 2 allowance in the source's compliance account occurred before such transaction or was anticipated to occur after such transaction), then the surrender requirement under paragraph (e)(2)(i) of this section corresponding to such CSAPR NO_X Ozone Season Group 2 allowance shall apply to the most recent former owners and operators of the source before the occurrence of such a transaction.

(C) The Administrator will not adjudicate any private legal dispute among the owners and operators of a source or among the former owners and operators of a source, including any disputes relating to the requirements to surrender CSAPR NO_X Ozone Season Group 2 allowances for the source under paragraph (e)(2)(i) of this section.

(3)(i) As soon as practicable on or after [EFFECTIVE DATE OF FINAL RULE], the Administrator will send a notification to the designated representative for each source described in paragraph (e)(1) of this section identifying the amounts of CSAPR NO_X Ozone Season Group 2 allowances allocated for each control period after 2022 and recorded in the source's compliance account and the corresponding surrender requirements for the source under paragraph (e)(2)(i) of this section.

(ii) As soon as practicable on or after [15 DAYS AFTER EFFECTIVE DATE OF FINAL RULE], the Administrator will deduct from the compliance account for each source described in paragraph (e)(1) of this section CSAPR NO_X Ozone Season Group 2 allowances eligible to satisfy the surrender requirements for the source under paragraph (e)(2)(i) of this section until all such surrender requirements for the source are satisfied or until no more CSAPR NO_X Ozone Season Group 2 allowances eligible to satisfy such surrender requirements remain in such compliance account.

(iii) As soon as practicable after completion of the deductions under paragraph (e)(3)(ii) of this section, the Administrator will identify for each source described in paragraph (e)(1) of this section the amounts, if any, of CSAPR NO_X Ozone Season Group 2 allowances allocated for each control period after 2022 and recorded in the source's compliance account for which the corresponding surrender requirements under paragraph (e)(2)(i) of this section have not been satisfied and will send a notification concerning such identified amounts to the designated representative for the source.

(iv) With regard to each source for which unsatisfied surrender requirements under paragraph (e)(2)(i) of this section remain after the deductions under paragraph (e)(3)(ii) of this section:

(A) Except as provided in paragraph (e)(3)(iv)(B) of this section, not later than September 15, 2023, the owners and operators of the source shall hold sufficient CSAPR NO_X Ozone Season Group 2 allowances eligible to satisfy such unsatisfied surrender requirements under paragraph (e)(2)(i) of this section in the source's compliance account.

(B) With regard to any portion of such unsatisfied surrender requirements that apply to former owners and operators of the source pursuant to paragraph (e)(2)(ii)(B) of this section, not later than September 15, 2023, such former owners and operators shall hold sufficient CSAPR NO_X Ozone Season Group 2 allowances eligible to satisfy such portion of the unsatisfied surrender requirements under paragraph (e)(2)(i) of this section either in the source's compliance account or in another Allowance Management System account identified to the Administrator on or before such date in a submission by the authorized account representative for such account.

(C) As soon as practicable on or after September 15, 2023, the Administrator will deduct from the Allowance Management System account identified in accordance with paragraph (e)(3)(iv)(A) or (B) of this section CSAPR NO_X Ozone Season Group 2 allowances eligible to satisfy the surrender requirements for the source under paragraph (e)(2)(i) of this section until all such surrender requirements for the source are satisfied or until no more CSAPR NO_X Ozone Season Group 2 allowances eligible to satisfy such surrender requirements remain in such account.

(v) When making deductions under paragraph (e)(3)(ii) or (iv) of this section to address the surrender requirements under paragraph (e)(2)(i) of this section for a given source:

(A) The Administrator will make deductions to address any surrender requirements with regard to first the 2023 control period and then the 2024 control period.

(B) When making deductions to address the surrender requirements with regard to a given control period, the Administrator will first deduct CSAPR NO_X Ozone Season Group 2 allowances allocated for such given control period and will then deduct CSAPR NO_X Ozone Season Group 2 allowances allocated for each successively earlier control period in sequence.

(C) When deducting CSAPR NO_X Ozone Season Group 2 allowances allocated for a given control period from a given Allowance Management System account, the Administrator will first deduct CSAPR NO_X Ozone Season Group 2 allowances initially recorded in the account under § 97.821 (if the account is a compliance account) in the order of recordation and will then deduct CSAPR NO_X Ozone Season Group 2 allowances recorded in the account under § 97.526(d) or § 97.823 in the order of recordation.

(4)(i) To the extent the surrender requirements under paragraph (e)(2)(i) of this section corresponding to any CSAPR NO_X Ozone Season Group 2 allowances allocated for a control period after 2022 and initially recorded in a given source's compliance account have not been fully satisfied through the deductions under paragraph (e)(3) of this section, as soon as practicable on or after November 15, 2023, the Administrator will deduct such initially recorded CSAPR NO_X Ozone Season Group 2 allowances from any Allowance Management System accounts in which such CSAPR NO_X Ozone Season Group 2 allowances are held, making such deductions in any order determined by the Administrator, until all such surrender requirements for such source have been satisfied or until all such CSAPR NO_X Ozone Season Group 2 allowances have been deducted, except as provided in paragraph (e)(4)(ii) of this section.

(ii) If no person with an ownership interest in a given CSAPR NO_X Ozone Season Group 2 allowance as of April 30, 2022, was an owner or operator of the source in whose compliance account such CSAPR NO_X Ozone Season Group 2 allowance was initially recorded, was a direct or indirect parent or subsidiary of an owner or operator of such source, or was directly or indirectly under common ownership with an owner or operator of such source, the Administrator will not deduct such CSAPR NO_X Ozone Season Group 2 allowance under paragraph (e)(4)(i) of this section. For purposes of this paragraph, each owner or operator of a source shall be deemed to be a person with an ownership interest in any CSAPR NO_X Ozone Season Group 2 allowance held in that source's compliance account. The limitation established by this paragraph on the deductibility of certain CSAPR NO_X Ozone Season Group 2 allowances under paragraph (e)(4)(i) of this section shall not be construed as a waiver of the surrender requirements under paragraph (e)(2)(i) of this section corresponding to such CSAPR NO_X Ozone Season Group 2 allowances.

(iii) Not less than 45 days before the planned date for any deductions under paragraph (e)(4)(i) of this section, the Administrator will send a notification to the authorized account representative for the Allowance Management System account from which such deductions will be made identifying the CSAPR NO_X Ozone Season Group 2 allowances to be deducted and the data upon which the Administrator has relied and specifying a process for submission of any objections to such data. Any objections must be submitted to the Administrator not later than 15 days before the planned date for such deductions as indicated in such notification.

(5) To the extent the surrender requirements under paragraph (e)(2)(i) of this section corresponding to any CSAPR NO_X Ozone Season Group 2 allowances allocated for a control period after 2022 and initially recorded in a given source's compliance account have not been fully satisfied through the deductions under paragraphs (e)(3) and (4) of this section:

(i) The persons identified in accordance with paragraph (e)(2)(ii) of this section with regard to such source and each such CSAPR NO_X Ozone Season Group 2 allowance shall pay any fine, penalty, or assessment or comply with any other remedy imposed under the Clean Air Act; and

(ii) Each such CSAPR NO_X Ozone Season Group 2 allowance, and each day in such control period, shall constitute a separate violation of this subpart and the Clean Air Act.

(6) The Administrator will record in the appropriate Allowance Management System accounts all deductions of CSAPR NO_X Ozone Season Group 2 allowances under paragraphs (e)(3) and (4) of this section.

(7)(i) Each submission, objection, or other written communication from a designated representative, authorized account representative, or other person to the Administrator under paragraph (e)(2), (3), or (4) of this section shall be sent electronically to the email address *CSAPR@epa.gov.* Each such communication from a designated representative must contain the certification statement set forth in § 97.814(a), and each such communication from the authorized account representative for a general account must contain the certification statement set forth in § 97.820(c)(2)(ii).

(ii) Each notification from the Administrator to a designated representative or authorized account representative under paragraph (e)(3) or (4) of this section will be sent electronically to the email address most recently received by the Administrator for such representative. In any such notification, the Administrator may provide information by means of a reference to a publicly accessible website where the information is available.

§ 97.812 [Amended]

■ 64. Amend § 97.812 by:

■ a. In paragraph (a) introductory text, removing ''State, the Administrator'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, the Administrator'';

■ b. In paragraphs (a)(3)(iii) and (a)(5), adding ''and areas of Indian country within the borders of the State subject to the State's SIP authority'' after ''in the State'';

■ c. In paragraph (a)(10), removing ''State, is allocated'' and adding in its place ''State and areas of Indian country within the borders of the State subject to the State's SIP authority, is allocated'';

■ d. In paragraph (b) introductory text, removing ''Indian country within the borders of each State, the Administrator'' and adding in its place ''areas of Indian country within the borders of each State not subject to the State's SIP authority, the Administrator''; and

■ e. In paragraph (b)(5), removing ''Indian country within the borders of the State'' and adding in its place ''areas of Indian country within the borders of the State not subject to the State's SIP authority''.

§ 97.821 [Amended]

■ 65. In § 97.821, amend paragraph (f) by removing ''2022'' and adding in its place ''2024'', and removing ''third'' before ''year after the year''.

§ 97.825 [Amended]

■ 66. In § 97.825, amend paragraphs (a) introductory text, (a)(2), (b)(1)(i), (b)(1)(ii)(A) and (B), (b)(3), (b)(4)(i), (b)(5), (b)(6)(i), (b)(6)(iii) introductory text, and (b)(6)(iii)(A) and (B) by removing ''base CSAPR'' and adding in its place ''CSAPR'' each time it appears.

■ 67. Amend § 97.826 by:

■ a. In paragraph (b), removing ''(c) or (d)'' and adding in its place ''(c), (d), or (e)'';

■ b. In paragraph (c), removing ''State (or Indian'' and adding in its place ''State (and Indian'';

■ c. In paragraphs (d)(1)(i)(A) and (B), removing ''§ 52.38(b)(2)(iv)'' and adding in its place ''§ 52.38(b)(2)(ii)(B)'';

■ d. Revising paragraph (d)(1)(i)(C);

■ e. In paragraph (d)(1)(ii) introductory text, removing ''§ 52.38(b)(2)(v)'' and adding in its place ''§ 52.38(b)(2)(iii)'';

■ f. Removing and reserving paragraph (d)(1)(iii);

■ g. Revising paragraph (d)(1)(iv) introductory text;

■ h. In paragraphs (d)(1)(iv)(A) and (B), removing ''or (d)(1)(iii)(C)'';

■ i. In paragraphs (d)(2)(i) and (d)(3), removing ''§ 52.38(b)(2)(v) of this chapter (or'' and adding in its place ''§ 52.38(b)(2)(iii) of this chapter (and'';

■ j. Redesignating paragraph (e) as paragraph (f) and adding a new paragraph (e);

■ k. Revising newly redesignated paragraphs (f)(1) and (2); and

■ l. Adding paragraph (f)(3).

The revisions and additions read as follows:

§ 97.826 Banking and conversion.

* * * * *

(d) * * *

(1) * * *

(i) * * *

(C) The full-season CSAPR NO_X Ozone Season Group 3 allowance bank target, computed as the sum for all States listed in § 52.38(b)(2)(iii)(A) of this chapter of the variability limits under § 97.1010(e) for such States for the control period in 2022.

* * * * *

(iv) For the compliance account of each source to which an amount of CSAPR NO_X Ozone Season Group 3 allowances greater than zero is allocated under paragraph (d)(1)(ii)(C) of this section:

* * * * *

(e) Notwithstanding any other provision of this subpart, part 52 of this chapter, or any SIP revision approved under § 52.38(b)(8) or (9) of this chapter:

(1) By [45 DAYS AFTER EFFECTIVE DATE OF FINAL RULE], the Administrator will temporarily suspend acceptance of CSAPR NO_X Ozone Season Group 2 allowance transfers submitted under § 97.822 and, before resuming acceptance of such transfers, will take the following actions with regard to every general account and every compliance account except a compliance account for a CSAPR NO_X Ozone Season Group 2 source in a State listed in § 52.38(b)(2)(ii)(A) of this chapter (and Indian country within the borders of such a State):

(i) The Administrator will deduct all CSAPR NO_X Ozone Season Group 2 allowances allocated for the control periods in 2017 through 2022 from each such account.

(ii) The Administrator will determine a conversion factor equal to the greater of 1.0000 or the quotient, expressed to four decimal places, of the sum of all CSAPR NO_X Ozone Season Group 2 allowances deducted from all such accounts under paragraph (e)(1)(i) of this section divided by the sum of the variability limits for the control period in 2024 under § 97.1010(e) for all States listed in § 52.38(b)(2)(iii)(B) of this chapter.

(iii) The Administrator will allocate and record in each such account an amount of CSAPR NO_X Ozone Season Group 3 allowances for the control period in 2023 computed as the quotient, rounded up to the nearest allowance, of the number of CSAPR NO_X Ozone Season Group 2 allowances deducted from such account under paragraph (e)(1)(i) of this section divided by the conversion factor determined under paragraph (e)(1)(ii) of this section, except as provided in paragraph (e)(1)(iv) or (v) of this section.

(iv) Where, pursuant to paragraph (e)(1)(i) of this section, the Administrator deducts CSAPR NO_X Ozone Season Group 2 allowances from the compliance account for a source in a State not listed in § 52.38(b)(2)(iii) of this chapter (and Indian country within the borders of such a State), the Administrator will not record CSAPR NO_X Ozone Season Group 3 allowances in that compliance account but instead will allocate and record the amount of CSAPR NO_X Ozone Season Group 3 allowances for the control period in 2023 computed for such source in accordance with paragraph (e)(1)(iii) of this section in a general account identified by the designated representative for such source, provided that if the designated representative fails to identify such a general account in a submission to the Administrator by [45 DAYS AFTER EFFECTIVE DATE OF FINAL RULE], the Administrator may record such CSAPR NO_X Ozone Season Group 3 allowances in a general account identified or established by the Administrator with the designated representative as the authorized account representative and with the owners and operators of such source (as indicated on the certificate of representation for the source) as the persons represented by the authorized account representative.

(v)(A) In computing any amounts of CSAPR NO_X Ozone Season Group 3 allowances to be allocated to and recorded in general accounts under paragraph (e)(1)(iii) of this section, the Administrator may group multiple general accounts whose ownership interests are held by the same or related persons or entities and treat the group of accounts as a single account for purposes of such computation.

(B) Following a computation for a group of general accounts in accordance with paragraph (e)(1)(v)(A) of this section, the Administrator will allocate to and record in each individual account in such group a proportional share of the quantity of CSAPR NO_X Ozone Season Group 3 allowances computed for such group, basing such shares on the respective quantities of CSAPR NO_X Ozone Season Group 2 allowances removed from such individual accounts under paragraph (e)(1)(i) of this section.

(C) In determining the proportional shares under paragraph (e)(1)(v)(B) of this section, the Administrator may employ any reasonable adjustment methodology to truncate or round each such share up or down to a whole number and to cause the total of such whole numbers to equal the amount of CSAPR NO_X Ozone Season Group 3 allowances computed for such group of accounts in accordance with paragraph (e)(1)(v)(A) of this section, even where such adjustments cause the numbers of CSAPR NO_X Ozone Season Group 3 allowances allocated to some individual accounts to equal zero.

(2) After the Administrator has carried out the procedures set forth in paragraph (e)(1) of this section, upon any determination that would otherwise result in the initial recordation of a given number of CSAPR NO_X Ozone Season Group 2 allowances in the compliance account for a source in a State listed in § 52.38(b)(2)(iii)(B) of this chapter (and Indian country within the borders of such a State), the Administrator will not record such CSAPR NO_X Ozone Season Group 2 allowances but instead will allocate and record in such account an amount of CSAPR NO_X Ozone Season Group 3 allowances for the control period in 2023 computed as the quotient, rounded up to the nearest allowance, of such given number of CSAPR NO_X Ozone Season Group 2 allowances divided by the conversion factor determined under paragraph (e)(1)(ii) of this section.

(f) * * *

(1) Except as provided in paragraph (f)(3) of this section, after the Administrator has carried out the procedures set forth in paragraph (d)(1) of this section, the owner or operator of a CSAPR NO_X Ozone Season Group 2 source in a State listed in § 52.38(b)(2)(iii)(A) of this chapter (and Indian country within the borders of such a State) may satisfy a requirement to hold a given number of CSAPR NO_X Ozone Season Group 2 allowances for the control period in a year from 2017 through 2020 by holding instead, in a general account established for this sole purpose, an amount of CSAPR NO_X Ozone Season Group 3 allowances for the control period in 2021 (or any later control period for which the allowance transfer deadline defined in § 97.1002 has passed) computed as the quotient, rounded up to the nearest allowance, of such given number of CSAPR NO_X Ozone Season Group 2 allowances divided by the conversion factor determined under paragraph (d)(1)(i)(D) of this section.

(2) Except as provided in paragraph (f)(3) of this section, after the Administrator has carried out the procedures set forth in paragraph (e)(1) of this section, the owner or operator of a CSAPR NO_X Ozone Season Group 2 source in a State listed in § 52.38(b)(2)(iii)(B) of this chapter (and Indian country within the borders of such a State) may satisfy a requirement to hold a given number of CSAPR NO_X Ozone Season Group 2 allowances for the control period in a year from 2017 through 2022 by holding instead, in a general account established for this sole purpose, an amount of CSAPR NO_X Ozone Season Group 3 allowances for the control period in 2023 (or any later control period for which the allowance transfer deadline defined in § 97.1002 has passed) computed as the quotient, rounded up to the nearest allowance, of such given number of CSAPR NO_X Ozone Season Group 2 allowances divided by the conversion factor determined under paragraph (e)(1)(ii) of this section.

(3) CSAPR NO_X Ozone Season Group 3 allowances may not be used to satisfy requirements to surrender CSAPR NO_X Ozone Season Group 2 allowances under § 97.811(d) or (e).

Subpart FFFFF—Texas SO_2 Trading Program

■ 68. Amend § 97.902 by:

■ a. In the definition of ''alternate designated representative'', removing ''Program or CSAPR NO_X Ozone Season Group 2 Trading Program, then'' and adding in its place ''Program, CSAPR NO_X Ozone Season Group 2 Trading Program, or CSAPR NO_X Ozone Season Group 3 Trading Program, then'';

■ b. In the definition of ''CSAPR NO_X Ozone Season Group 2 Trading Program'', removing ''(b)(2)(iii) and (iv), and'' and adding in its place ''(b)(2)(ii), and'';

■ c. Adding in alphabetical order a definition for ''CSAPR NO_X Ozone Season Group 3 Trading Program''; and

■ d. In the definition of ''designated representative'', removing ''Program or CSAPR NO_X Ozone Season Group 2 Trading Program, then'' and adding in its place ''Program, CSAPR NO_X Ozone Season Group 2 Trading Program, or CSAPR NO_X Ozone Season Group 3 Trading Program, then''.

The addition reads as follows:

§ 97.902 Definitions.

* * * * *

CSAPR NO_X Ozone Season Group 3 Trading Program means a multi-state

NO_X air pollution control and emission reduction program established in accordance with subpart GGGGG of this part and § 52.38(b)(1), (b)(2)(iii), and (b)(10) through (14) and (17) of this chapter (including such a program that is revised in a SIP revision approved by the Administrator under § 52.38(b)(10) or (11) of this chapter or that is established in a SIP revision approved by the Administrator under § 52.38(b)(12) of this chapter), as a means of mitigating interstate transport of ozone and NO_X.

* * * * *

§ 97.921 [Amended]

■ 69. In § 97.921, amend paragraph (b)(2) by removing ''2022'' and adding in its place ''2024'', and removing ''third'' before ''year after the year''.

§ 97.934 [Amended]

■ 70. In § 97.934, amend paragraph (d)(3) by removing ''Program or CSAPR NO_X Ozone Season Group 2 Trading Program, quarterly'' and adding in its place ''Program, CSAPR NO_X Ozone Season Group 2 Trading Program, or CSAPR NO_X Ozone Season Group 3 Trading Program, quarterly''.

Subpart GGGGG—CSAPR NO_X Ozone Season Group 3 Trading Program

■ 71. Amend § 97.1002 by:
■ a. Revising the definition of ''allocate or allocation'';
■ b. In the definition of ''allowance transfer deadline'', adding ''primary'' before ''emissions limitation'';
■ c. In the definition of ''alternate designated representative'', removing ''or CSAPR SO_2 Group 1 Trading Program, then'' and adding in its place ''CSAPR SO_2 Group 1 Trading Program, or CSAPR SO_2 Group 2 Trading Program, then'';
■ d. Adding in alphabetical order a definition for ''backstop daily NO_X emissions rate'';
■ e. In the definition of ''common designated representative's assurance level'', in paragraph (1), removing ''§ 97.1010(b)'' and adding in its place ''§ 97.1010(e)'', and revising paragraph (2);
■ f. In the definition of ''compliance account'', adding ''primary'' before ''emissions limitation'';
■ g. Adding in alphabetical order a definition for ''CSAPR NO_X Ozone Season Group 1 Trading Program'';
■ h. In the definition of ''CSAPR NO_X Ozone Season Group 2 Trading Program'', removing ''(b)(2)(iii) and (iv), and'' and adding in its place ''(b)(2)(ii), and'';
■ i. In the definition of ''CSAPR NO_X Ozone Season Group 3 allowance'', adding ''or (e)'' after ''§ 97.826(d)'', and adding ''or less'' after ''one ton'';
■ j. In the definition of ''CSAPR NO_X Ozone Season Group 3 allowance deduction or deduct CSAPR NO_X Ozone Season Group 3 allowances'', adding ''primary'' before ''emissions limitation'';
■ k. In the definition of ''CSAPR NO_X Ozone Season Group 3 emissions limitation'', adding ''primary'' before ''emissions limitation'';
■ l. Adding in alphabetical order a definition for ''CSAPR NO_X Ozone Season Group 3 secondary emissions limitation'';
■ m. In the definition of ''CSAPR NO_X Ozone Season Group 3 Trading Program'', removing ''(b)(2)(v), and'' and adding in its place ''(b)(2)(iii), and'';
■ n. Adding in alphabetical order a definition for ''CSAPR SO_2 Group 2 Trading Program'';
■ o. In the definition of ''designated representative'', removing ''or CSAPR SO_2 Group 1 Trading Program, then'' and adding in its place ''CSAPR SO_2 Group 1 Trading Program, or CSAPR SO_2 Group 2 Trading Program, then''.
■ p. In the definition of ''excess emissions'', adding ''primary'' before ''emissions limitation''; and
■ q. In the definition of ''State'', removing ''(b)(2)(v), and'' and adding in its place ''(b)(2)(iii), and''.

The revisions and additions read as follows:

§ 97.1002 Definitions.

* * * * *

Allocate or *allocation* means, with regard to CSAPR NO_X Ozone Season Group 3 allowances, the determination by the Administrator, State, or permitting authority, in accordance with this subpart, §§ 97.526(d) and 97.826(d) and (e), and any SIP revision submitted by the State and approved by the Administrator under § 52.38(b)(10), (11), or (12) of this chapter, of the amount of such CSAPR NO_X Ozone Season Group 3 allowances to be initially credited, at no cost to the recipient, to:

(1) A CSAPR NO_X Ozone Season Group 3 unit;

(2) A new unit set-aside;

(3) An Indian country new unit set-aside;

(4) An Indian country existing unit set-aside; or

(5) An entity not listed in paragraphs (1) through (4) of this definition;

(6) Provided that, if the Administrator, State, or permitting authority initially credits, to a CSAPR NO_X Ozone Season Group 3 unit qualifying for an initial credit, a credit in the amount of zero CSAPR NO_X Ozone Season Group 3 allowances, the CSAPR NO_X Ozone Season Group 3 unit will be treated as being allocated an amount (*i.e.,* zero) of CSAPR NO_X Ozone Season Group 3 allowances.

* * * * *

Backstop daily NO_X emissions rate means an emissions rate limit used in the determination of the CSAPR NO_X Ozone Season Group 3 primary emissions limitation for a CSAPR NO_X Ozone Season Group 3 source in accordance with § 97.1024(b).

* * * * *

Common designated representative's assurance level * * *

(2) Provided that the allocations of CSAPR NO_X Ozone Season Group 3 allowances for any control period taken into account for purposes of this definition shall exclude any CSAPR NO_X Ozone Season Group 3 allowances allocated for such control period under § 97.526(d) or § 97.826(d) or (e).

* * * * *

CSAPR NO_X Ozone Season Group 1 Trading Program means a multi-state NO_X air pollution control and emission reduction program established in accordance with subpart BBBBB of this part and § 52.38(b)(1), (b)(2)(i), and (b)(3) through (5) and (13) through (15) of this chapter (including such a program that is revised in a SIP revision approved by the Administrator under § 52.38(b)(3) or (4) of this chapter or that is established in a SIP revision approved by the Administrator under § 52.38(b)(5) of this chapter), as a means of mitigating interstate transport of ozone and NO_X.

* * * * *

CSAPR NO_X Ozone Season Group 3 secondary emissions limitation means, for a CSAPR NO_X Ozone Season Group 3 unit to which such a limitation applies under § 97.1025(c)(1) for a control period in a given year, the tonnage of NO_X emissions calculated for the unit in accordance with § 97.1025(c)(2) for such control period.

* * * * *

CSAPR SO_2 Group 2 Trading Program means a multi-state SO_2 air pollution control and emission reduction program established in accordance with subpart DDDDD of this part and § 52.39(a), (c), (g) through (k), and (m) of this chapter (including such a program that is revised in a SIP revision approved by the Administrator under § 52.39(g) or (h) of this chapter or that is established in a SIP revision approved by the Administrator under § 52.39(i) of this chapter), as a means of mitigating interstate transport of fine particulates and SO_2.

* * * * *

■ 72. Amend § 97.1006 by:

■ a. Revising paragraph (b)(2), the paragraph (c)(1) heading, paragraph (c)(1)(i), and paragraph (c)(1)(ii) introductory text;

■ b. Adding paragraphs (c)(1)(iii) and (iv); and

■ c. Revising paragraphs (c)(2)(iii) and (c)(3).

The revisions and additions read as follows:

§ 97.1006 Standard requirements.

* * * * *

(b) * * *

(2) The emissions and heat input data determined in accordance with §§ 97.1030 through 97.1035 shall be used to calculate allocations of CSAPR NO_X Ozone Season Group 3 allowances under §§ 97.1011 and 97.1012 and to determine compliance with the CSAPR NO_X Ozone Season Group 3 primary and secondary emissions limitations and assurance provisions under paragraph (c) of this section, provided that, for each monitoring location from which mass emissions are reported, the mass emissions amount used in calculating such allocations and determining such compliance shall be the mass emissions amount for the monitoring location determined in accordance with §§ 97.1030 through 97.1035 and rounded to the nearest ton, with any fraction of a ton less than 0.50 being deemed to be zero.

(c) * * *

(1) *CSAPR NO_X Ozone Season Group 3 primary and secondary emissions limitations*—(i) *Primary emissions limitation.* As of the allowance transfer deadline for a control period in a given year, the owners and operators of each CSAPR NO_X Ozone Season Group 3 source and each CSAPR NO_X Ozone Season Group 3 unit at the source shall hold, in the source's compliance account, CSAPR NO_X Ozone Season Group 3 allowances available for deduction for such control period under § 97.1024(a) in an amount not less than the amount determined under § 97.1024(b), comprising the sum of:

(A) The tons of total NO_X emissions for such control period from all CSAPR NO_X Ozone Season Group 3 units at the source; plus

(B) Two times the sum, for all CSAPR NO_X Ozone Season Group 3 units at the source and all days of the control period, of any NO_X emissions from such a unit on any day of the control period exceeding the NO_X emissions that would have occurred on that day if the unit had combusted the same daily heat input and emitted at any backstop daily NO_X emissions rate applicable to the unit for that control period.

(ii) *Exceedances of primary emissions limitation.* If total NO_X emissions during a control period in a given year from the CSAPR NO_X Ozone Season Group 3 units at a CSAPR NO_X Ozone Season Group 3 source are in excess of the CSAPR NO_X Ozone Season Group 3 primary emissions limitation set forth in paragraph (c)(1)(i) of this section, then:

* * * * *

(iii) *Secondary emissions limitation.* The owner or operator of a base CSAPR NO_X Ozone Season Group 3 unit subject to an emissions limitation under § 97.1025(c)(1) shall not discharge, or allow to be discharged, emissions of NO_X to the atmosphere during a control period in excess of the tonnage amount calculated in accordance with § 97.1025(c)(2).

(iv) *Exceedances of secondary emissions limitation.* If total NO_X emissions during a control period in a given year from a base CSAPR NO_X Ozone Season Group 3 unit are in excess of the amount of a CSAPR NO_X Ozone Season Group 3 secondary emissions limitation applicable to the unit for the control period under paragraph (c)(1)(iii) of this section, then the owners and operators of the unit and the source at which the unit is located shall pay any fine, penalty, or assessment or comply with any other remedy imposed, for the same violations, under the Clean Air Act, and each ton of such excess emissions and each day of such control period shall constitute a separate violation of this subpart and the Clean Air Act.

(2) * * *

(iii) Total NO_X emissions from all base CSAPR NO_X Ozone Season Group 3 units at base CSAPR NO_X Ozone Season Group 3 sources in a State (and Indian country within the borders of such State) during a control period in a given year exceed the State assurance level if such total NO_X emissions exceed the sum, for such control period, of the State NO_X Ozone Season Group 3 trading budget under § 97.1010(a) and the State's variability limit under § 97.1010(e).

* * * * *

(3) *Compliance periods.*(i) A CSAPR NO_X Ozone Season Group 3 unit shall be subject to the requirements under paragraphs (c)(1)(i) and (ii) of this section, and a base CSAPR NO_X Ozone Season Group 3 unit shall be subject to the requirements under paragraph (c)(2) of this section, for the control period starting on the later of the applicable date in paragraph (c)(3)(i)(A), (B), or (C) of this section or the deadline for meeting the unit's monitor certification requirements under § 97.1030(b) and for each control period thereafter:

(A) May 1, 2021, for a unit in a State (and Indian country within the borders of such State) listed in § 52.38(b)(2)(iii)(A) of this chapter;

(B) May 1, 2023, for a unit in a State (and Indian country within the borders of such State) listed in § 52.38(b)(2)(iii)(B) of this chapter; or

(C) [EFFECTIVE DATE OF FINAL RULE], for a unit in a State (and Indian country within the borders of such State) listed in § 52.38(b)(2)(iii)(C) of this chapter.

(ii) A base CSAPR NO_X Ozone Season Group 3 unit shall be subject to the requirements under paragraphs (c)(1)(iii) and (iv) of this section for the control period starting on the later of May 1, 2024 or the deadline for meeting the unit's monitor certification requirements under § 97.1030(b) and for each control period thereafter.

* * * * *

■ 73. Revise § 97.1010 to read as follows:

§ 97.1010 State NO_X Ozone Season Group 3 trading budgets, set-asides, and variability limits.

(a) *State NO_X Ozone Season Group 3 trading budgets.* (1)(i) The State NO_X Ozone Season Group 3 trading budgets for allocations of CSAPR NO_X Ozone Season Group 3 allowances for the control periods in 2021, 2022, 2023, and 2024 are as indicated in Table 1 to this paragraph, subject to prorating for the control period in 2023 as provided in paragraph (a)(1)(ii) of this section:

TABLE 1 TO PARAGRAPH (a)(1)(i)—STATE NO_X OZONE SEASON GROUP 3 TRADING BUDGETS BY CONTROL PERIOD

[Tons]

State	2021	2022	Portion of 2023 control period before [EFFECTIVE DATE OF FINAL RULE], before prorating	Portion of 2023 control period on and after [EFFECTIVE DATE OF FINAL RULE], before prorating	2024
Alabama			13,211	6,364	6,306
Arkansas			9,210	8,889	8,889
Delaware				384	434
Illinois	11,223	9,102	8,179	7,364	7,463
Indiana	17,004	12,582	12,553	11,151	9,391

(ii) For the control period in 2023, the State NO_X Ozone Season Group 3 trading budget for each State shall be calculated as the sum of the following prorated amounts, rounded to the nearest allowance:

(A) The product of the non-prorated trading budget for the portion of the 2023 control period before [EFFECTIVE DATE OF FINAL RULE] shown for the State in Table 1 to paragraph (a)(1)(i) of this section (or zero if Table 1 shows no amount for such portion of the 2023 control period for the State) multiplied by a fraction whose numerator is the number of days from May 1, 2023 through the day before [EFFECTIVE DATE OF FINAL RULE], inclusive, and whose denominator is 153; and

(B) The product of the non-prorated trading budget for the portion of the 2023 control period on and after [EFFECTIVE DATE OF FINAL RULE] shown for the State in Table 1 to paragraph (a)(1)(i) of this section multiplied by a fraction whose numerator is the number of days from [EFFECTIVE DATE OF FINAL RULE] through September 30, 2023, inclusive, and whose denominator is 153.

(2) The State NO_X Ozone Season Group 3 trading budget for each State and each control period in 2025 and thereafter shall be the amount provided for the State and control period in the applicable notice of data availability issued under paragraph (a)(3)(v)(C) of this section.

(3) The Administrator will calculate the State NO_X Ozone Season Group 3 trading budget for each State and each control period in 2025 and thereafter in the year before the year of the control period as follows:

(i) The State's trading budget for the control period shall be calculated as the sum (converted to tons at a conversion factor of 2,000 lb/ton and rounded to the nearest ton), for all units identified for inclusion in the calculation under paragraph (a)(3)(ii) of this section, of the product for each such unit of the NO_X emissions rate in lb/mmBtu identified for the unit under paragraph (a)(3)(iii) of this section multiplied by the heat input in mmBtu identified for the unit under paragraph (a)(3)(iv) of this section.

(ii) A unit in a State (and Indian country within the borders of the State) shall be included in the calculation of the State's trading budget for a control period if:

(A) The unit was included in the calculation of the State's trading budget for the immediately preceding control period; or

(B) The unit's deadline for certification of monitoring systems under § 97.1030(b) is on or before May 1 of the year two years before the year of the control period (*e.g.,* May 1, 2023 for calculation of the trading budget for the control period in 2025);

(C) Provided that a unit shall not be included in the calculation of a State's trading budget for a control period if, before completing such calculation, the Administrator determines that the unit is not actually a CSAPR NO_X Ozone Season Group 3 unit.

(iii) For each unit included in the calculation of the State's trading budget for a control period, the NO_X emissions rate in lb/mmBtu used in the calculation shall be identified as follows:

(A) For a unit listed in the table entitled ''Dynamic Budget 2023 Template'' and ''Dynamic Budget 2026+ Template'' posted at *www.regulations.gov* with docket identification number EPA–HQ–OAR–2021–0668–[XXXX], the NO_X emissions rate used in the calculation for the control period shall be the NO_X emissions rate shown for the unit and control period in the tables.

(B) For a unit not listed in the table referenced in paragraph (a)(3)(iii)(A) of this section, the NO_X emissions rate used in the calculation for the control period shall be identified according to the type of unit and the type of fuel combusted by the unit during the control period beginning May 1 on or immediately after the unit's deadline for certification of monitoring systems under § 97.1030(b) as follows:

(*1*) 0.012 lb/mmBtu, for a combined cycle combustion turbine other than an integrated coal gasification combined cycle unit;

(*2*) 0.030 lb/mmBtu, for a simple cycle combustion turbine or a boiler combusting only fuel oil or gaseous fuel (other than coal-derived fuel) during such control period; or

(*3*) 0.050 lb/mmBtu, for a boiler combusting any amount of coal or coal-derived fuel during such control period or any other unit not covered by paragraph (a)(3)(iii)(B)(*1*) or (*2*) of this section.

(iv) For each unit included in the calculation of the State's trading budget for a control period, the heat input in mmBtu used in the calculation shall be identified as follows:

(A) Except as provided in paragraph (a)(3)(iv)(B) of this section, the heat input used in the calculation for the control period shall be the heat input reported for the unit for the control period in the year two years before the year of the control period (*e.g.,* heat input reported for the control period in 2023 shall be used in calculating the trading budget for the control period in 2025).

(B) If no heat input data were reported for the unit for the control period in the year two years before the year of the control period and the heat input used for the unit in calculating the State's trading budget for the control period in 2024 was an estimate rather than the unit's actual reported heat input for the control period in 2021 or an earlier year, the same estimated heat input used in calculating the State's trading budget for the control period in 2024 shall be used in the calculations of the State's trading budgets for the control periods in 2025 and 2026.

(v)(A) By March 1, 2024 and March 1 of each year thereafter, the Administrator will calculate the State CSAPR NO_X Ozone Season Group 3 trading budget for each State, in accordance with paragraph (a)(3)(i) through (iv) of this section and §§ 97.1006(b)(2) and 97.1030 through 97.1035, for the control period in the year after the year of the applicable calculation deadline under this paragraph and will promulgate a notice of data availability of the results of the calculations.

(B) For each notice of data availability required in paragraph (a)(3)(v)(A) of this section, the Administrator will provide an opportunity for submission of objections to the calculations referenced in such notice. Objections shall be submitted by the deadline specified in such notice and shall be limited to addressing whether the calculations (including the identification of the units included in the calculations) are in accordance with the provisions referenced in paragraph (a)(3)(v)(A) of this section.

(C) The Administrator will adjust the calculations to the extent necessary to ensure that they are in accordance with the provisions referenced in paragraph (a)(3)(v)(A) of this section. By May 1 immediately after the promulgation of each notice of data availability required in paragraph (a)(3)(v)(A) of this section, the Administrator will promulgate a notice of data availability of the results of the calculations incorporating any adjustments that the Administrator determines to be necessary and the reasons for accepting or rejecting any objections submitted in accordance with paragraph (a)(3)(v)(B) of this section.

(b) *New unit set-asides.* (1) The States' new unit set-asides for allocations of CSAPR NO_X Ozone Season Group 3 allowances for the control periods in 2021, 2022, 2023, and 2024 are as indicated in Table 2 to this paragraph:

TABLE 2 TO PARAGRAPH (b)(1)—NEW UNIT SET-ASIDES BY CONTROL PERIOD

[Tons]

State	2021	2022	2023	2024
Alabama			191	189
Arkansas			178	178
Delaware			54	61
Illinois	265	265	368	373
Indiana	262	254	223	188
Kentucky	309	283	233	233
Louisiana	430	430	186	186
Maryland	135	115	24	24
Michigan	500	482	429	429

West Virginia	266	261	250	250
Wisconsin			119	101
Wyoming			274	257

(2) The new unit set-aside for allocations of CSAPR NO_X Ozone Season Group 3 allowances for each State for each control period in 2025 and thereafter shall be calculated as the product (rounded to the nearest allowance) of the State NO_X Ozone Season Group 3 trading budget determined for the State and control period under paragraph (a)(2) of this section multiplied by 0.02.

(c) *Indian country new unit set-asides for the control periods in 2021 and 2022.* The States' Indian country new unit set-asides for allocations of CSAPR NO_X Ozone Season Group 3 allowances for the control periods in 2021 and 2022 are as indicated in Table 3 to this paragraph:

TABLE 3 TO PARAGRAPH (c)—INDIAN COUNTRY NEW UNIT SET-ASIDES BY CONTROL PERIOD

[Tons]

State	2021	2022
Alabama

(d) *Indian country existing unit set-asides for the control periods in 2023 and thereafter.* The Indian country existing unit set-aside for allocations of CSAPR NO_X Ozone Season Group 3 allowances for each State for each control period in 2023 and thereafter shall be calculated as the sum of all allowance allocations to units in areas of Indian country within the borders of the State not subject to the State's SIP authority as provided in the applicable notice of data availability for the control period referenced in § 97.1011(a)(2).

(e) *Variability limits.* (1) The variability limit for the State NO_X Ozone Season Group 3 trading budget for each State for each control period from 2021 through 2024 shall be calculated as the product (rounded to the nearest ton) of the State NO_X Ozone Season Group 3 trading budget determined for the State and control period in accordance with paragraph (a)(1) of this section multiplied by 0.21.

(2) The variability limit for the State NO_X Ozone Season Group 3 trading budget for each State for each control period in 2025 and thereafter shall be calculated as the product (rounded to the nearest ton) of the State NO_X Ozone Season Group 3 trading budget determined for the State and control period in accordance with paragraph (a)(2) of this section multiplied by the greater of:

(i) 0.21; or

(ii) Any excess over 1.00 of the quotient (rounded to two decimal places) of the total heat input reported for the control period for all CSAPR NO_X Ozone Season Group 3 units in the State and Indian country within the borders of the State divided by the total heat input used in the calculation of the State's trading budget for the control period under paragraph (a)(3) of this section.

(f) *Relationship of trading budgets, set-asides, and variability limits.* Each State NO_X Ozone Season Group 3 trading budget in this section includes any tons in a new unit set-aside, Indian country new unit set-aside, or Indian country existing unit set-aside but does not include any tons in a variability limit.

■ 74. Amend § 97.1011 by revising the section heading and paragraphs (a), (b), and (c)(1) and (5) to read as follows:

§ 97.1011 CSAPR NO_X Ozone Season Group 3 allowance allocations to existing units.

(a) *Allocations to existing units in general.* (1) For the control periods in 2021 and each year thereafter, CSAPR NO_X Ozone Season Group 3 allowances will be allocated to units in each State and areas of Indian country within the borders of the State subject to the State's SIP authority as provided in notices of data availability issued by the Administrator. Starting with the control period in 2025, the notices of data availability will be the notices issued under paragraph (b)(10)(iii) of this section.

(2) For the control periods in 2023 and each year thereafter, CSAPR NO_X Ozone Season Group 3 allowances will be allocated to units in areas of Indian country within the borders of each State not subject to the State's SIP authority as provided in notices of data availability issued by the Administrator. Starting with the control period in 2025, the notices of data availability will be the notices issued under paragraph (b)(10)(iii) of this section.

(3) Providing an allocation to a unit in a notice of data availability does not constitute a determination that the unit is a CSAPR NO_X Ozone Season Group 3 unit, and not providing an allocation to a unit in such notice does not constitute a determination that the unit is not a CSAPR NO_X Ozone Season Group 3 unit.

(b) *Calculation of default allocations to existing units for control periods in 2025 and thereafter.* For each control period in 2025 and thereafter, and for the CSAPR NO_X Ozone Season Group 3 units in each State and areas of Indian country within the borders of the State, the Administrator will calculate default allocations of CSAPR NO_X Ozone Season Group 3 allowances to the CSAPR NO_X Ozone Season Group 3 units as follows:

(1) For each State and control period, the total amount of CSAPR NO_X Ozone Season Group 3 allowances for which default allocations will be calculated will be the remainder of the State NO_X Ozone Season Group 3 trading budget for the control period under § 97.1010(a)(2) minus the new unit set-aside for the control period under § 97.1010(b)(2).

(2) A default allocation of CSAPR NO_X Ozone Season Group 3 allowances will be calculated for a CSAPR NO_X Ozone Season Group 3 unit in the State and Indian country within the borders of the State for a control period if:

(i) The unit meets the conditions under § 97.1010(a)(3)(ii) to be included in the calculation of the State's trading budget for the control period; and

(ii) The unit reported heat input greater than zero for the control period in the year two years before the year of the control period.

(3) For each CSAPR NO_X Ozone Season Group 3 unit for which a default allocation is being calculated for a control period, the Administrator will determine the following amounts for the five-year historical period ending with the year two years before the year of the control period for which default allocations are being calculated:

(i) The total heat input reported for the unit in accordance with part 75 of this chapter for the control period in each year of the five-year historical period;

(ii) The average of the three highest of the total heat input values determined for the unit under paragraph (b)(3)(i) of this section or, if fewer than three non-zero values were determined for the unit, the average of all such non-zero heat input values;

(iii) The total NO_X emissions reported for the unit in accordance with part 75 of this chapter for the control period in each year of the five-year historical period; and

(iv) The maximum of the total NO_X emissions values determined for the unit under paragraph (b)(3)(iii) of this section.

(4) The Administrator will calculate the initial unrounded default allocations for each CSAPR NO_X Ozone Season Group 3 unit according to the procedure in paragraph (b)(5) of this section and will recalculate the unrounded default allocations according to the procedures in paragraph (b)(6) or (7) of this section, as applicable, iterating the recalculations as necessary until the total of the unrounded default allocations to all eligible units equals the amount of allowances determined for the State under paragraph (b)(1) of this section.

(5) The Administrator will calculate the initial unrounded default allocations to CSAPR NO_X Ozone Season Group 3 units as follows:

(i) The Administrator will calculate the sum, for all units determined under paragraph (b)(2) of this section to be eligible to receive a default allocation, of the units' average heat input determined under paragraph (b)(3)(ii) of this section.

(ii) For each unit determined under paragraph (b)(2) of this section to be eligible to receive a default allocation, the Administrator will calculate the unit's unrounded default allocation as the lesser of:

(A) The product of the total amount of allowances determined for the State and control period under paragraph (b)(1) of this section multiplied by a fraction whose numerator is the unit's average heat input determined under paragraph (b)(3)(ii) of this section and whose denominator is the sum determined under paragraph (b)(5)(i) of this section; and

(B) The unit's maximum total NO_X emissions determined under paragraph (b)(3)(iv) of this section.

(iii) If the sum of the unrounded default allocations determined under paragraph (b)(5)(ii) of this section is less than the total amount of allowances determined for the State and control period under paragraph (b)(1) of this section, the Administrator will follow the procedures in paragraph (b)(6) or (7) of this section, as applicable.

(iv) If the sum of the unrounded default allocations determined under paragraph (b)(5)(ii) of this section equals the total amount of allowances determined for the State and control period under paragraph (b)(1) of this section, the Administrator will determine the rounded default allocations according to the procedures in paragraphs (b)(8) and (9) of this section.

(6) If the unrounded default allocation determined in the previous round of the calculation procedure for at least one CSAPR NO_X Ozone Season Group 3 unit is less than the unit's maximum total NO_X emissions determined under paragraph (b)(3)(iv) of this section, the Administrator will recalculate the unrounded default allocations as follows:

(i) The Administrator will calculate the additional pool of allowances to be allocated as the remainder of the total amount of allowances determined for the State and control period under paragraph (b)(1) of this section minus the sum of the unrounded default allocations from the previous round of the calculation procedure for all units determined under paragraph (b)(2) of this section to be eligible to receive a default allocation.

(ii) The Administrator will calculate the sum, for all units whose unrounded default allocations determined in the previous round of the calculation procedure were less than the respective units' maximum total NO_X emissions determined under paragraph (b)(3)(iv) of this section, of the units' average heat input determined under paragraph (b)(3)(ii) of this section.

(iii) For each unit whose unrounded default allocation determined in the previous round of the calculation was less than the unit's maximum total NO_X emissions determined under paragraph (b)(3)(iv) of this section, the Administrator will recalculate the unit's unrounded default allocation, before rounding, as the lesser of:

(A) The sum of the unit's unrounded default allocation determined in the previous round of the calculation procedure plus the product of the additional pool of allowances determined under paragraph (b)(6)(i) of this section multiplied by a fraction whose numerator is the unit's average heat input determined under paragraph (b)(3)(ii) of this section and whose denominator is the sum determined under paragraph (b)(6)(ii) of this section; and

(B) The unit's maximum total NO_X emissions determined under paragraph (b)(3)(iv) of this section.

(iv) Except as provided in paragraph (b)(6)(iii) of this section, a unit's unrounded default allocation shall equal the amount determined in the previous round of the calculation procedure.

(v) If the sum of the unrounded default allocations determined under paragraphs (b)(6)(iii) and (iv) of this section is less than the total amount of allowances determined for the State and control period under paragraph (b)(1) of this section, the Administrator will iterate the procedures in paragraph (b)(6) of this section or follow the procedures in paragraph (b)(7) of this section, as applicable.

(vi) If the sum of the unrounded default allocations determined under paragraphs (b)(6)(iii) and (iv) of this section equals the total amount of allowances determined for the State and control period under paragraph (b)(1) of this section, the Administrator will determine the rounded default allocations according to the procedures in paragraphs (b)(8) and (9) of this section.

(7) If the unrounded default allocation determined in the previous round of the calculation procedure for every CSAPR NO_X Ozone Season Group 3 unit equals the unit's maximum total NO_X emissions determined under paragraph (b)(3)(iv) of this section, the Administrator will recalculate the unrounded default allocations as follows:

(i) The Administrator will calculate the additional pool of allowances to be allocated as the remainder of the total amount of allowances determined for the State and control period under paragraph (b)(1) of this section minus the sum of the unrounded default allocations from the previous round for all units determined under paragraph (b)(2) of this section to be eligible to receive a default allocation.

(ii) The Administrator will recalculate the unrounded default allocation for each eligible unit as the sum of:

(A) The unit's unrounded default allocation as determined in the previous round of the calculation procedure; plus

(B) The product of the additional pool of allowances determined under paragraph (b)(7)(i) of this section multiplied by a fraction whose numerator is the unit's average heat input determined under paragraph (b)(3)(ii) of this section and whose denominator is the sum determined under paragraph (b)(5)(i) of this section.

(8) The Administrator will round the default allocation for each eligible unit determined under paragraph (b)(5), (6), or (7) of this section to the nearest allowance and make any adjustments required under paragraph (b)(9) of this section.

(9) If the sum of the default allocations after rounding under paragraph (b)(8) of this section does not equal the total amount of allowances determined for the State and control period under paragraph (b)(1) of this

section, the Administrator will adjust the default allocations as follows. The Administrator will list the CSAPR NO_X Ozone Season Group 3 units in descending order based on such units' allocation amounts under paragraph (b)(8) of this section and, in cases of equal allocation amounts, in alphabetical order of the relevant sources' names and numerical order of the relevant units' identification numbers, and will adjust each unit's allocation amount upward or downward by one CSAPR NO_X Ozone Season Group 3 allowance (but not below zero) in the order in which the units are listed, and will repeat this adjustment process as necessary, until the total of the adjusted default allocations equals the total amount of allowances determined for the State and control period under paragraph (b)(1) of this section.

(10)(i) By March 1, 2024 and March 1 of each year thereafter, the Administrator will calculate the default allocation of CSAPR NO_X Ozone Season Group 3 allowances to each CSAPR NO_X Ozone Season Group 3 unit in a State and Indian country within the borders of the State, in accordance with paragraphs (b)(1) through (9) of this section and §§ 97.1006(b)(2) and 97.1030 through 97.1035, for the control period in the year after the year of the applicable calculation deadline under this paragraph and will promulgate a notice of data availability of the results of the calculations.

(ii) For each notice of data availability required in paragraph (b)(10)(i) of this section, the Administrator will provide an opportunity for submission of objections to the calculations referenced in such notice. Objections shall be submitted by the deadline specified in such notice of data availability and shall be limited to addressing whether the calculations (including the identification of the CSAPR NO_X Ozone Season Group 3 units) are in accordance with the provisions referenced in paragraph (b)(10)(i) of this section.

(iii) The Administrator will adjust the calculations to the extent necessary to ensure that they are in accordance with the provisions referenced in paragraph (b)(10)(i) of this section. By May 1 immediately after the promulgation of each notice of data availability required in paragraph (b)(10)(i) of this section, the Administrator will promulgate a notice of data availability of the results of the calculations incorporating any adjustments that the Administrator determines to be necessary and the reasons for accepting or rejecting any objections submitted in accordance with paragraph (b)(10)(ii) of this section.

(c) *Incorrect allocations of CSAPR NO_X Ozone Season Group 3 allowances to existing units.* (1) For each control period in 2021 and thereafter, if the Administrator determines that CSAPR NO_X Ozone Season Group 3 allowances were allocated for the control period to a recipient covered by the provisions of paragraph (c)(1)(i), (ii), or (iii) of this section, then the Administrator will notify the designated representative of the recipient and will act in accordance with the procedures set forth in paragraphs (c)(2) through (5) of this section:

(i) The recipient is not actually a CSAPR NO_X Ozone Season Group 3 unit under § 97.1004 as of the first day of the control period and is allocated CSAPR NO_X Ozone Season Group 3 allowances for such control period under paragraph (a)(1) or (2) of this section;

(ii) The recipient is not actually a CSAPR NO_X Ozone Season Group 3 unit under § 97.1004 as of the first day of the control period and is allocated CSAPR NO_X Ozone Season Group 3 allowances for such control period under a provision of a SIP revision approved under § 52.38(b)(10), (11), or (12) of this chapter that the SIP revision provides should be allocated only to recipients that are CSAPR NO_X Ozone Season Group 3 units as of the first day of such control period; or

(iii) The recipient is not located as of the first day of the control period in the State (and Indian country within the borders of the State) from whose NO_X Ozone Season Group 3 trading budget the CSAPR NO_X Ozone Season Group 3 allowances allocated under paragraph (a)(1) or (2) of this section, or under a provision of a SIP revision approved under § 52.38(b)(10), (11), or (12) of this chapter, were allocated for such control period.

* * * * *

(5) With regard to any CSAPR NO_X Ozone Season Group 3 allowances that are not recorded, or that are deducted as an incorrect allocation, in accordance with paragraphs (c)(2) and (3) of this section:

(i) If the non-recordation decision under paragraph (c)(2) of this section or the deduction under paragraph (c)(3) of this section occurs on or before May 1, 2024, the Administrator will transfer the CSAPR NO_X Ozone Season Group 3 allowances to the new unit set-aside for 2021, 2022, or 2023 for the State from whose NO_X Ozone Season Group 3 trading budget the CSAPR NO_X Ozone Season Group 3 allowances were allocated.

(ii) If the non-recordation decision under paragraph (c)(2) of this section or the deduction under paragraph (c)(3) of this section occurs after May 1, 2024 and on or before May 1 of the year following the year of the control period for which the CSAPR NO_X Ozone Season Group 3 allowances were allocated, the Administrator will transfer the CSAPR NO_X Ozone Season Group 3 allowances to the new unit set-aside for such control period for the State from whose NO_X Ozone Season Group 3 trading budget the CSAPR NO_X Ozone Season Group 3 allowances were allocated.

(iii) If the non-recordation decision under paragraph (c)(2) of this section or the deduction under paragraph (c)(3) of this section occurs after May 1, 2024 and after May 1 of the year following the year of the control period for which the CSAPR NO_X Ozone Season Group 3 allowances were allocated, the Administrator will transfer the CSAPR NO_X Ozone Season Group 3 allowances to a surrender account.

■ 75. Amend § 97.1012 by:
■ a. Revising paragraphs (a) introductory text and (a)(1)(i) and (ii);
■ b. Removing paragraphs (a)(1)(iii) and (iv);
■ c. Revising paragraphs (a)(2) and (a)(3)(i);
■ d. In paragraph (a)(3)(ii), adding ''and'' after the semicolon;
■ e. Revising paragraph (a)(3)(iii);
■ f. Removing paragraph (a)(3)(iv);
■ g. Revising paragraphs (a)(5) and (10):
■ h. In paragraph (a)(11), removing ''§ 97.1011(b)(1)(i), (ii), and (v), of'' and adding in its place ''paragraph (a)(13) of this section, of'';
■ i. Adding paragraph (a)(13);
■ j. Revising paragraphs (b) introductory text and (b)(1) and (2);
■ k. In paragraph (b)(5), removing ''Indian country within the borders of the State'' and adding in its place ''areas of Indian country within the borders of the State not subject to the State's SIP authority'';
■ l. Revising paragraph (b)(10);
■ m. In paragraph (b)(11), removing ''§ 97.1011(b)(2)(i), (ii), and (v), of'' and adding in its place ''paragraph (b)(13) of this section, of''; and
■ n. Adding paragraphs (b)(13) and (c).

The revisions and additions read as follows:

§ 97.1012 CSAPR NO_X Ozone Season Group 3 allowance allocations to new units.

(a) *Allocations from new unit set-asides.* For each control period in 2021 and thereafter for a State listed in § 52.38(b)(2)(iii)(A) of this chapter, or 2023 and thereafter for a State listed in § 52.38(b)(2)(iii)(B) or (C) of this chapter, and for the CSAPR NO_X Ozone Season Group 3 units in each State and areas of

Indian country within the borders of the State (except, for the control periods in 2021 and 2022, areas of Indian country within the borders of the State not subject to the State's SIP authority), the Administrator will allocate CSAPR NO_X Ozone Season Group 3 allowances to the CSAPR NO_X Ozone Season Group 3 units as follows:

(1) * * *

(i) CSAPR NO_X Ozone Season Group 3 units that are not allocated an amount of CSAPR NO_X Ozone Season Group 3 allowances for such control period in the applicable notice of data availability referenced in § 97.1011(a)(1) or (2) and that have deadlines for certification of monitoring systems under § 97.1030(b) not later than September 30 of the year of the control period; or

(ii) CSAPR NO_X Ozone Season Group 3 units whose allocation of an amount of CSAPR NO_X Ozone Season Group 3 allowances for such control period in the applicable notice of data availability referenced in § 97.1011(a)(1) or (2) is covered by § 97.1011(c)(2) or (3).

(2) The Administrator will establish a separate new unit set-aside for the State for each such control period. Each such new unit set-aside will be allocated CSAPR NO_X Ozone Season Group 3 allowances in an amount equal to the applicable amount of tons of NO_X emissions as set forth in § 97.1010(b) and will be allocated additional CSAPR NO_X Ozone Season Group 3 allowances (if any) in accordance with § 97.1011(c)(5) and paragraphs (b)(10) and (c)(5) of this section.

(3) * * *

(i) The control period in 2021, for a State listed in § 52.38(b)(2)(iii)(A) of this chapter, or the control period in 2023, for a State listed in § 52.38(b)(2)(iii)(B) or (C) of this chapter;

* * * * *

(iii) For a unit described in paragraph (a)(1)(ii) of this section, the first control period in which the CSAPR NO_X Ozone Season Group 3 unit operates in the State and Indian country within the borders of the State (except, for the control periods in 2021 and 2022, areas of Indian country within the borders of the State not subject to the State's SIP authority) after operating in another jurisdiction and for which the unit is not already allocated one or more CSAPR NO_X Ozone Season Group 3 allowances.

* * * * *

(5) The Administrator will calculate the sum of the allocation amounts of CSAPR NO_X Ozone Season Group 3 allowances determined for all such CSAPR NO_X Ozone Season Group 3 units under paragraph (a)(4)(i) of this section in the State and Indian country within the borders of the State (except, for the control periods in 2021 and 2022, areas of Indian country within the borders of the State not subject to the State's SIP authority) for such control period.

* * * * *

(10)(i) For a control period in 2021 or 2022, if, after completion of the procedures under paragraphs (a)(2) through (7) and (12) of this section for a control period, any unallocated CSAPR NO_X Ozone Season Group 3 allowances remain in the new unit set-aside for the State for such control period, the Administrator will allocate to each CSAPR NO_X Ozone Season Group 3 unit that is in the State and areas of Indian country within the borders of the State subject to the State's SIP authority and is allocated an amount of CSAPR NO_X Ozone Season Group 3 allowances for the control period in the applicable notice of data availability referenced in § 97.1011(a)(1) an amount of CSAPR NO_X Ozone Season Group 3 allowances equal to the following: The total amount of such remaining unallocated CSAPR NO_X Ozone Season Group 3 allowances in such new unit set-aside, multiplied by the unit's allocation under § 97.1011(a)(1) for such control period, divided by the remainder of the amount of tons in the applicable State NO_X Ozone Season Group 3 trading budget minus the sum of the amounts of tons in such new unit set-aside and the Indian country new unit set-aside for the State for such control period, and rounded to the nearest allowance.

(ii) For a control period in 2023 or thereafter, if, after completion of the procedures under paragraphs (a)(2) through (7) and (12) of this section for a control period, any unallocated CSAPR NO_X Ozone Season Group 3 allowances remain in the new unit set-aside for the State for such control period, the Administrator will allocate to each CSAPR NO_X Ozone Season Group 3 unit that is in the State and Indian country within the borders of the State and is allocated an amount of CSAPR NO_X Ozone Season Group 3 allowances for the control period by the Administrator in the applicable notice of data availability referenced in § 97.1011(a)(1) or (2), or under a provision of a SIP revision approved under § 52.38(b)(10), (11), or (12) of this chapter, an amount of CSAPR NO_X Ozone Season Group 3 allowances equal to the following: The total amount of such remaining unallocated CSAPR NO_X Ozone Season Group 3 allowances in such new unit set-aside, multiplied by the unit's allocation under § 97.1011(a)(1) or (2) or a provision of a SIP revision approved under § 52.38(b)(10), (11), or (12) of this chapter for such control period, divided by the remainder of the amount of tons in the applicable State NO_X Ozone Season Group 3 trading budget minus the amount of tons in such new unit set-aside for the State for such control period, and rounded to the nearest allowance.

* * * * *

(13)(i) By March 1, 2022 and March 1 of each year thereafter, the Administrator will calculate the CSAPR NO_X Ozone Season Group 3 allowance allocation to each CSAPR NO_X Ozone Season Group 3 unit in a State and Indian country within the borders of the State (except, for the control periods in 2021 and 2022, areas of Indian country within the State not subject to the State's SIP authority), in accordance with paragraphs (a)(2) through (7), (10), and (12) of this section and §§ 97.1006(b)(2) and 97.1030 through 97.1035, for the control period in the year before the year of the applicable calculation deadline under this paragraph and will promulgate a notice of data availability of the results of the calculations.

(ii) For each notice of data availability required in paragraph (a)(13)(i) of this section, the Administrator will provide an opportunity for submission of objections to the calculations referenced in such notice. Objections shall be submitted by the deadline specified in such notice and shall be limited to addressing whether the calculations (including the identification of the CSAPR NO_X Ozone Season Group 3 units) are in accordance with the provisions referenced in paragraph (a)(13)(i) of this section.

(iii) The Administrator will adjust the calculations to the extent necessary to ensure that they are in accordance with the provisions referenced in paragraph (a)(13)(i) of this section. By May 1 immediately after the promulgation of each notice of data availability required in paragraph (a)(13)(i) of this section, the Administrator will promulgate a notice of data availability of the results of the calculations incorporating any adjustments that the Administrator determines to be necessary and the reasons for accepting or rejecting any objections submitted in accordance with paragraph (a)(13)(ii) of this section.

(b) *Allocations from Indian country new unit set-asides.* For the control periods in 2021 and 2022, for a State listed in § 52.38(b)(2)(iii)(A) of this chapter, and for the CSAPR NO_X Ozone

Season Group 3 units in areas of Indian country within the borders of each such State not subject to the State's SIP authority, the Administrator will allocate CSAPR NO_X Ozone Season Group 3 allowances to the CSAPR NO_X Ozone Season Group 3 units as follows:

(1) The CSAPR NO_X Ozone Season Group 3 allowances will be allocated to CSAPR NO_X Ozone Season Group 3 units that are not allocated an amount of CSAPR NO_X Ozone Season Group 3 allowances for such control period in the applicable notice of data availability issued under § 97.1011(a)(1) and that have deadlines for certification of monitoring systems under § 97.1030(b) not later than September 30 of the year of the control period, except as provided in paragraph (b)(10) of this section.

(2) The Administrator will establish a separate Indian country new unit set-aside for the State for each such control period. Each such Indian country new unit set-aside will be allocated CSAPR NO_X Ozone Season Group 3 allowances in an amount equal to the applicable amount of tons of NO_X emissions as set forth in § 97.1010(c) and will be allocated additional CSAPR NO_X Ozone Season Group 3 allowances (if any) in accordance with paragraph (c)(5) of this section.

* * * * *

(10) If, after completion of the procedures under paragraphs (b)(2) through (7) and (12) of this section for a control period, any unallocated CSAPR NO_X Ozone Season Group 3 allowances remain in the Indian country new unit set-aside for the State for such control period, the Administrator will transfer such unallocated CSAPR NO_X Ozone Season Group 3 allowances to the new unit set-aside for the State for such control period.

* * * * *

(13)(i) By March 1, 2022 and March 1, 2023, the Administrator will calculate the CSAPR NO_X Ozone Season Group 3 allowance allocation to each CSAPR NO_X Ozone Season Group 3 unit in areas of Indian country within the borders of a State not subject to the State's SIP authority, in accordance with paragraphs (b)(2) through (7), (10), and (12) of this section and §§ 97.1006(b)(2) and 97.1030 through 97.1035, for the control period in the year before the year of the applicable calculation deadline under this paragraph and will promulgate a notice of data availability of the results of the calculations.

(ii) For each notice of data availability required in paragraph (b)(13)(i) of this section, the Administrator will provide an opportunity for submission of objections to the calculations referenced in such notice. Objections shall be submitted by the deadline specified in such notice and shall be limited to addressing whether the calculations (including the identification of the CSAPR NO_X Ozone Season Group 3 units) are in accordance with the provisions referenced in paragraph (b)(13)(i) of this section.

(iii) The Administrator will adjust the calculations to the extent necessary to ensure that they are in accordance with the provisions referenced in paragraph (b)(13)(i) of this section. By May 1 immediately after the promulgation of each notice of data availability required in paragraph (b)(13)(i) of this section, the Administrator will promulgate a notice of data availability of the results of the calculations incorporating any adjustments that the Administrator determines to be necessary and the reasons for accepting or rejecting any objections submitted in accordance with paragraph (b)(13)(ii) of this section.

(c) *Incorrect allocations of CSAPR NO_X Ozone Season Group 3 allowances to new units.* (1) For each control period in 2021 and thereafter, if the Administrator determines that CSAPR NO_X Ozone Season Group 3 allowances were allocated for the control period under paragraphs (a)(2) through (7) and (12) of this section or paragraphs (b)(2) through (7) and (12) of this section to a recipient that is not actually a CSAPR NO_X Ozone Season Group 3 unit under § 97.1004 as of the first day of such control period, then the Administrator will notify the designated representative of the recipient and will act in accordance with the procedures set forth in paragraphs (c)(2) through (5) of this section.

(2) Except as provided in paragraph (c)(3) or (4) of this section, the Administrator will not record such CSAPR NO_X Ozone Season Group 3 allowances under § 97.1021.

(3) If the Administrator already recorded such CSAPR NO_X Ozone Season Group 3 allowances under § 97.1021 and if the Administrator makes the determination under paragraph (c)(1) of this section before making deductions for the source that includes such recipient under § 97.1024(b) for such control period, then the Administrator will deduct from the account in which such CSAPR NO_X Ozone Season Group 3 allowances were recorded an amount of CSAPR NO_X Ozone Season Group 3 allowances allocated for the same or a prior control period equal to the amount of such already recorded CSAPR NO_X Ozone Season Group 3 allowances. The authorized account representative shall ensure that there are sufficient CSAPR NO_X Ozone Season Group 3 allowances in such account for completion of the deduction.

(4) If the Administrator already recorded such CSAPR NO_X Ozone Season Group 3 allowances under § 97.1021 and if the Administrator makes the determination under paragraph (c)(1) of this section after making deductions for the source that includes such recipient under § 97.1024(b) for such control period, then the Administrator will not make any deduction to take account of such already recorded CSAPR NO_X Ozone Season Group 3 allowances.

(5) With regard to any CSAPR NO_X Ozone Season Group 3 allowances that are not recorded, or that are deducted as an incorrect allocation, in accordance with paragraphs (c)(2) and (3) of this section:

(i) If the non-recordation decision under paragraph (c)(2) of this section or the deduction under paragraph (c)(3) of this section occurs on or before May 1, 2023, the Administrator will transfer the CSAPR NO_X Ozone Season Group 3 allowances to the new unit set-aside, in the case of allowances allocated under paragraph (a) of this section, or the Indian country new unit set-aside, in the case of allowances allocated under paragraph (b) of this section, for the control period in 2021 or 2022 for the State from whose NO_X Ozone Season Group 3 trading budget the CSAPR NO_X Ozone Season Group 3 allowances were allocated.

(ii) If the non-recordation decision under paragraph (c)(2) of this section or the deduction under paragraph (c)(3) of this section occurs after May 1, 2023 and on or before May 1, 2024, the Administrator will transfer the CSAPR NO_X Ozone Season Group 3 allowances to the new unit set-aside for the control period in 2023 for the State from whose NO_X Ozone Season Group 3 trading budget the CSAPR NO_X Ozone Season Group 3 allowances were allocated.

(iii) If the non-recordation decision under paragraph (c)(2) of this section or the deduction under paragraph (c)(3) of this section occurs after May 1, 2024, the Administrator will transfer the CSAPR NO_X Ozone Season Group 3 allowances to a surrender account.

■ 76. Amend § 97.1021 by:

■ a. In paragraph (a), removing "§ 97.1011(a)" and adding in its place "§ 97.1011(a)(1)";

■ b. Revising paragraph (b);

■ c. Removing and reserving paragraph (c);

■ d. Revising paragraph (d);

■ e. Adding paragraph (e);

■ f. Revising paragraphs (f) and (g);

■ g. In paragraph (h), removing ''May 1 of each year thereafter, the'' and adding in its place ''May 1, 2023, the'';
■ h. Adding paragraphs (i) and (j); and
■ i. In paragraph (m), adding ''or (e)'' after ''§ 97.811(d)'' each time it appears.

The revisions and addition read as follows:

§ 97.1021 Recordation of CSAPR NO_X Ozone Season Group 3 allowance allocations and auction results.

* * * * *

(b) By July 29, 2021, the Administrator will record in each CSAPR NO_X Ozone Season Group 3 source's compliance account the CSAPR NO_X Ozone Season Group 3 allowances allocated to the CSAPR NO_X Ozone Season Group 3 units at the source in accordance with § 97.1011(a)(1) for the control period in 2022.

* * * * *

(d) By [30 DAYS AFTER EFFECTIVE DATE OF FINAL RULE], the Administrator will record in each CSAPR NO_X Ozone Season Group 3 source's compliance account the CSAPR NO_X Ozone Season Group 3 allowances allocated to the CSAPR NO_X Ozone Season Group 3 units at the source in accordance with § 97.1011(a)(1) for the control period in 2023.

(e) By [30 DAYS AFTER EFFECTIVE DATE OF FINAL RULE], the Administrator will record in each CSAPR NO_X Ozone Season Group 3 source's compliance account the CSAPR NO_X Ozone Season Group 3 allowances allocated to the CSAPR NO_X Ozone Season Group 3 units at the source in accordance with § 97.1011(a)(1) for the control period in 2024, unless the State in which the source is located notifies the Administrator in writing by [EFFECTIVE DATE OF FINAL RULE] of the State's intent to submit to the Administrator a complete SIP revision by September 1, 2023 meeting the requirements of § 52.38(b)(10)(i) through (iv) of this chapter.

(1) If, by September 1, 2023 the State does not submit to the Administrator such complete SIP revision, the Administrator will record by September 15, 2023 in each CSAPR NO_X Ozone Season Group 3 source's compliance account the CSAPR NO_X Ozone Season Group 3 allowances allocated to the CSAPR NO_X Ozone Season Group 3 units at the source in accordance with § 97.1011(a)(1) for the control period in 2024.

(2) If the State submits to the Administrator by September 1, 2023 and the Administrator approves by March 1, 2024 such complete SIP revision, the Administrator will record by March 1, 2024 in each CSAPR NO_X Ozone Season Group 3 source's compliance account the CSAPR NO_X Ozone Season Group 3 allowances allocated to the CSAPR NO_X Ozone Season Group 3 units at the source as provided in such approved, complete SIP revision for the control period in 2024.

(3) If the State submits to the Administrator by September 1, 2023 and the Administrator does not approve by March 1, 2024 such complete SIP revision, the Administrator will record by March 1, 2024 in each CSAPR NO_X Ozone Season Group 3 source's compliance account the CSAPR NO_X Ozone Season Group 3 allowances allocated to the CSAPR NO_X Ozone Season Group 3 units at the source in accordance with § 97.1011(a)(1) for the control period in 2024.

(f) By July 1, 2024 and July 1 of each year thereafter, the Administrator will record in each CSAPR NO_X Ozone Season Group 3 source's compliance account the CSAPR NO_X Ozone Season Group 3 allowances allocated to the CSAPR NO_X Ozone Season Group 3 units at the source, or in each appropriate Allowance Management System account the CSAPR NO_X Ozone Season Group 3 allowances auctioned to CSAPR NO_X Ozone Season Group 3 units, in accordance with § 97.1011(a)(1), or with a SIP revision approved under § 52.38(b)(11) or (12) of this chapter, for the control period in the year after the year of the applicable recordation deadline under this paragraph.

(g) By May 1, 2022 and May 1 of each year thereafter, the Administrator will record in each CSAPR NO_X Ozone Season Group 3 source's compliance account the CSAPR NO_X Ozone Season Group 3 allowances allocated to the CSAPR NO_X Ozone Season Group 3 units at the source in accordance with § 97.1012(a) for the control period in the year before the year of the applicable recordation deadline under this paragraph.

* * * * *

(i) By [30 DAYS AFTER EFFECTIVE DATE OF FINAL RULE], the Administrator will record in each CSAPR NO_X Ozone Season Group 3 source's compliance account the CSAPR NO_X Ozone Season Group 3 allowances allocated to the CSAPR NO_X Ozone Season Group 3 units at the source in accordance with § 97.1011(a)(2) for the control periods in 2023 and 2024.

(j) By July 1, 2024 and July 1 of each year thereafter, the Administrator will record in each CSAPR NO_X Ozone Season Group 3 source's compliance account the CSAPR NO_X Ozone Season Group 3 allowances allocated to the CSAPR NO_X Ozone Season Group 3 units at the source in accordance with § 97.1011(a)(2) for the control period in the year after the year of the applicable recordation deadline under this paragraph.

* * * * *

■ 77. Amend § 97.1024 by:
■ a. Revising the section heading;
■ b. In paragraphs (a) introductory text and (b) introductory text, adding ''primary'' before ''emissions limitation'';
■ c. Revising paragraph (b)(1);
■ d. Adding paragraph (b)(3); and
■ e. In paragraph (c)(2)(ii), adding ''or (e)'' after ''§ 97.826(d)''.

The revisions and addition read as follows:

§ 97.1024 Compliance with CSAPR NO_X Ozone Season Group 3 primary emissions limitation.

* * * * *

(b) * * *

(1) Until the amount of CSAPR NO_X Ozone Season Group 3 allowances deducted equals the sum of:

(i) The number of tons of total NO_X emissions from all CSAPR NO_X Ozone Season Group 3 units at the source for such control period; plus

(ii) Two times the sum (converted to tons at a conversion factor of 2,000 lb/ton and rounded to the nearest ton), for all days in the control period and all CSAPR NO_X Ozone Season Group 3 units at the source to which backstop daily NO_X emissions rates apply for the control period under paragraph (b)(3) of this section, of any amount by which a unit's NO_X emissions for a given day in pounds exceed the product in pounds of the unit's total heat input in mmBtu for that day multiplied by the applicable backstop daily NO_X emissions rate in lb/mmBtu; or

* * * * *

(3) The applicable backstop daily NO_X emissions rates are as follows:

(i) For the control periods in 2024 and each year thereafter, a backstop daily NO_X emissions rate of 0.14 lb/mmBtu shall apply to each CSAPR NO_X Ozone Season Group 3 unit combusting any coal during the control period, serving a generator with nameplate capacity of 100 MW or more, and equipped with selective catalytic reduction controls, except a circulating fluidized bed boiler.

(ii) For the control periods in 2027 and each year thereafter, a backstop daily NO_X emissions rate of 0.14 lb/mmBtu shall apply to each CSAPR NO_X Ozone Season Group 3 unit combusting any coal during the control period and serving a generator with nameplate capacity of 100 MW or more, except a circulating fluidized bed boiler.

* * * * *

■ 78. Amend § 97.1025 by revising the section heading and adding paragraph (c) to read as follows:

§ 97.1025 Compliance with CSAPR NO_X Ozone Season Group 3 assurance provisions; CSAPR NO_X Ozone Season Group 3 secondary emissions limitation.

* * * * *

(c) *CSAPR NO_X Ozone Season Group 3 secondary emissions limitation.* (1) The owner or operator of a base CSAPR NO_X Ozone Season Group 3 unit shall not discharge, or allow to be discharged, emissions of NO_X to the atmosphere during a control period in excess of the tonnage amount calculated in accordance with paragraph (c)(2) of this section, provided that the emissions limitation established under this paragraph shall apply to a unit for a control period only if:

(i) The unit is included for the control period in a group of base CSAPR NO_X Ozone Season Group 3 units at base CSAPR NO_X Ozone Season Group 3 sources in a State (and Indian country within the borders of such State) having a common designated representative and the owners and operators of such units and sources are subject to a requirement for such control period to hold one or more CSAPR NO_X Ozone Season Group 3 allowances under § 97.1006(c)(2)(i) and paragraph (b) of this section with respect to such group; and

(ii) The unit was required to report NO_X emissions and heat input data for all or portions of at least 367 operating hours during the control period and all or portions of at least 367 operating hours during at least one previous control period under the CSAPR NO_X Ozone Season Group 1 Trading Program, CSAPR NO_X Ozone Season Group 2 Trading Program, or CSAPR NO_X Ozone Season Group 3 Trading Program.

(2) The amount of the emissions limitation applicable to a base CSAPR NO_X Ozone Season Group 3 unit for a control period under paragraph (c)(1) of this section, in tons of NO_X, shall be calculated as the sum of 50 plus the product (converted to tons at a conversion factor of 2,000 lb/ton and rounded to the nearest ton) of multiplying—

(i) The total heat input in mmBtu reported for the unit for the control period in accordance with §§ 97.1030 through 97.1035; and

(ii) A NO_X emission rate of 0.10 lb/mmBtu or, if higher, the product of 1.25 times the lowest seasonal average NO_X emission rate in lb/mmBtu achieved by the unit in any previous control period for which the unit was required to report NO_X emissions and heat input data for all or portions of at least 367 operating hours under the CSAPR NO_X Ozone Season Group 1 Trading Program, CSAPR NO_X Ozone Season Group 2 Trading Program, or CSAPR NO_X Ozone Season Group 3 Trading Program, where the unit's seasonal average NO_X emission rate for each such previous control period shall be calculated from such reported data as the quotient of the unit's total NO_X emissions in tons for the control period divided by the unit's total heat input in mmBtu for the control period, multiplied by a conversion factor of 2,000 lb/ton, and rounded to the nearest 0.0001 lb/mmBtu.

■ 79. Amend § 97.1026 by:

■ a. Revising paragraph (b);

■ b. In paragraph (c), removing ''State (or Indian'' and adding in its place ''State (and Indian''; and

■ c. Adding paragraph (d).

The revision and addition read as follows:

§ 97.1026 Banking.

* * * * *

(b) Any CSAPR NO_X Ozone Season Group 3 allowance that is held in a compliance account or a general account will remain in such account unless and until the CSAPR NO_X Ozone Season Group 3 allowance is deducted or transferred under § 97.1011(c), § 97.1012(c), § 97.1023, § 97.1024, § 97.1025, § 97.1027, or § 97.1028 or paragraph (c) or (d) of this section.

* * * * *

(d) Before the allowance transfer deadline for each control period in 2024 or a subsequent year, the Administrator will deduct amounts of CSAPR NO_X Ozone Season Group 3 allowances issued for the control periods in previous years exceeding the CSAPR NO_X Ozone Season Group 3 allowance bank ceiling target for the control period in accordance with paragraphs (d)(1) through (4) of this section.

(1) As soon as practicable on or after August 1, 2024 and August 1 of each subsequent year, the Administrator will temporarily suspend acceptance of CSAPR NO_X Ozone Season Group 3 allowance transfers submitted under § 97.1022 and, before resuming acceptance of such transfers, will take the actions in paragraphs (d)(2) through (4) of this section.

(2) The Administrator will determine each of the following values:

(i) The CSAPR NO_X Ozone Season Group 3 allowance bank ceiling target for the control period in the year of the deadline under paragraph (d)(1) of this section, calculated as the product, rounded to the nearest allowance, of 0.105 times the sum for all States listed in § 52.38(b)(2)(iii) of this chapter of the State NO_X Ozone Season Group 3 trading budgets under § 97.1010(a) for such States for such control period.

(ii) The total amount of CSAPR NO_X Ozone Season Group 3 allowances issued for control periods in years before the year of the deadline under paragraph (d)(1) of this section and held in all compliance and general accounts.

(3) If the CSAPR NO_X Ozone Season Group 3 allowance bank ceiling target determined under paragraph (d)(2)(i) of this section is less than the total amount of CSAPR NO_X Ozone Season Group 3 allowances determined under paragraph (d)(2)(ii) of this section, then for each compliance account or general account holding CSAPR NO_X Ozone Season Group 3 allowances issued for control periods in years before the year of the deadline under paragraph (d)(1) of this section, the Administrator will:

(i) Determine the total amount of CSAPR NO_X Ozone Season Group 3 allowances issued for control periods in years before the year of the deadline under paragraph (d)(1) of this section and held in the account.

(ii) Determine the account's share of the CSAPR NO_X Ozone Season Group 3 allowance bank ceiling target for the control period, calculated as the product, rounded up to the nearest allowance, of the CSAPR NO_X Ozone Season Group 3 allowance bank ceiling target determined under paragraph (d)(2)(i) of this section multiplied by a fraction whose numerator is the total amount of CSAPR NO_X Ozone Season Group 3 allowances held in the account determined under paragraph (d)(3)(i) of this section and whose denominator is the total amount of CSAPR NO_X Ozone Season Group 3 allowances held in all compliance and general accounts determined under paragraph (d)(2)(ii) of this section.

(iii) Deduct an amount of CSAPR NO_X Ozone Season Group 3 allowances issued for control periods in years before the year of the deadline under paragraph (d)(1) of this section equal to any positive remainder of the total amount of CSAPR NO_X Ozone Season Group 3 allowances held in the account determined under paragraph (d)(3)(i) of this section minus the account's share of the CSAPR NO_X Ozone Season Group 3 allowance bank ceiling target for the control period determined under paragraph (d)(3)(ii) of this section. The allowances will be deducted on a first-in, first-out basis in the order set forth in § 97.1024(c)(2)(i) and (ii).

(iv) Record the deductions under paragraph (d)(3)(iii) of this section in the account.

(4)(i) In computing any amounts of CSAPR NO_X Ozone Season Group 3 allowances to be deducted from general accounts under paragraph (d)(3) of this section, the Administrator may group multiple general accounts whose ownership interests are held by the same or related persons or entities and treat the group of accounts as a single account for purposes of such computation.

(ii) Following a computation for a group of general accounts in accordance with paragraph (d)(4)(i) of this section, the Administrator will deduct from and record in each individual account in such group a proportional share of the quantity of CSAPR NO_X Ozone Season Group 3 allowances computed for such group, basing such shares on the respective quantities of CSAPR NO_X Ozone Season Group 3 allowances determined for such individual accounts under paragraph (d)(3)(i) of this section.

(iii) In determining the proportional shares under paragraph (d)(4)(ii) of this section, the Administrator may employ any reasonable adjustment methodology to truncate or round each such share up or down to a whole number and to cause the total of such whole numbers to equal the amount of CSAPR NO_X Ozone Season Group 3 allowances computed for such group of accounts in accordance with paragraph (d)(4)(i) of this section, even where such adjustments cause the numbers of CSAPR NO_X Ozone Season Group 3 allowances remaining in some individual accounts following the deductions to equal zero.

■ 80. Amend § 97.1030 by:

■ a. Revising paragraph (b)(1); and

■ b. In paragraph (b)(3), removing ''(b)(2)'' and adding in its place ''(b)(1) or (2)''.

The revision reads as follows:

§ 97.1030 General monitoring, recordkeeping, and reporting requirements.

* * * * *

(b) * * *

ATTN: Docket ID No. EPA-HQ-OAR-2021-0668

Administrator Michael Regan
C/O EPA Docket Center (EPA/DC)
Docket ID No. EPA-HQ-OAR-2021-0668
U.S. Environmental Protection Agency

Submitted via Federal eRulemaking Portal (Regulations.gov)

RE: Comments of United States Steel Corporation ("U. S. Steel") on the "Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Primary Ozone National Ambient Air Quality Standard," Docket No. EPA-HQ-OAR-2021-0668, 87 Fed. Reg. 20,036 (April 6, 2022) ("Proposed Rule").

Dear Administrator Regan,

United States Steel Corporation ("U. S. Steel") on behalf of the company and all our subsidiaries[1] and affiliates appreciates the opportunity to submit the following comments to the United States Environmental Protection Agency ("EPA") regarding the proposed "Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Primary Ozone National Ambient Air Quality Standard" Docket No. EPA-HQ-OAR-2021-0668. *Federal Register* 87 Fed. Reg. 20,036 (April 6, 2022) ("Proposed Rule"). The Proposed Rule creates Ozone NOx Standards related to the Clean Air Act Good Neighbor provisions. The comment period for the Notice closes on June 21, 2022. U.S. Steel provides the following general and specific comments below related to the Proposed Rule.

[1] Big River Steel, LLC (BRS) and Exploratory Ventures, LLC (EV) are both wholly owned subsidiaries of U. S. Steel. BRS is an operating scrap to steel products facility in Osceola, Arkansas and EV is a scrap to steel products facility under construction in Osceola, Arkansas. These are only two of the U. S. Steel subsidiaries and facilities and these comments apply to all subsidiaries and locations however some comments may directly reference these locations.

INTRODUCTION

The Proposed Rule's treatment of non-EGUs, including the iron and steel industry, sharply departs from EPA practice and court interpretations of the Good Neighbor provision of the Clean Air Act (CAA). As more fully detailed herein, EPA treats EGUs and non-EGU sources (including the iron and steel industry) in fundamentally different ways, many of which directly conflict with past EPA determinations and court decisions without reasonable explanations for departure, including but not limited to:

- Setting statewide budget limits for EGUs, while instead subjecting iron and steel units to unit specific command and control limits without any evaluation of how the proposed limits relate to the amount of statewide reductions needed to eliminate a state's alleged substantial contribution;
- Allowing emissions trading for EGUs, but not for non-EGUs;
- Accounting for feasibility in evaluating applicability of EGU provisions to types of EGUs (e.g., waste incinerators) and which States to subject to the EGU provisions (e.g., California), but not performing any feasibility analysis, much less facility or unit specific feasibility analysis, for the iron and steel industry (indeed, ignoring all prior determinations, including recent determinations that post combustion controls[2] are not feasible for EAFs and other emission units the Proposed Rule would cover in the iron and steel industry);
- Modeling impacts and cost effectiveness of controls for EGUs as a single industry, but grouping all other covered industries together as "non-EGUs" for a single cost effectiveness analysis, without evaluating what level of controls would be cost effective for each of the separate industries the Proposed Rule would cover;
- Modeling the effect of multiple cost thresholds for EGUs as an industry ($1,600, $1,800, and $11,000) to evaluate whether lower cost thresholds could achieve sufficient reductions, but only modeling a single cost threshold ($7,500) for all non-EGUs without any consideration of whether a lower cost threshold for some or all such industries could still result in sufficient emission reductions to satisfy Good Neighbor requirements.

When determining what non-EGUs to regulate under the Proposed Rule, EPA also did not correctly follow the "4-step interstate transport framework" used by EPA in prior rulemakings and approved by the Supreme Court. Under that approach, EPA, after identifying nonattainment and maintenance receptors (step 1), and screening out any state not significantly contributing to any linked receptor (step 2), was then supposed to "(3) for states linked to downwind air quality

[2] The term "post-combustion controls" is used herein only for convenience and consistency with the way in which EPA describes emission controls such as SCR in the Proposed Rule. As described in more detail herein, some of the furnaces covered by the Proposed Rule, most notably an EAF, is not a combustion process, such that any downstream emission controls on an EAF would not technically be "post-combustion."

problems, identify [] upwind emissions that significantly contribute to downwind nonattainment or interfere with downwind maintenance of the NAAQS; and (4) for states that are found to have emissions that significantly contribute to nonattainment or interfere with maintenance of the NAAQS in downwind areas, implement[] the necessary emissions reductions through enforceable measures." But the EPA did not follow this approach in the Proposed Rule. Rather than evaluate the upwind emissions that actually contribute to each screened-in state's linked nonattainment or maintenance receptors, EPA instead just (1) identified industries nationwide that contributed relatively more than other industries, and (2) automatically mandated limits directly on all such industries in each screened-in state, skipping any finding that the industries (let alone specific sources) evaluated on a nationwide basis actually contributed to nonattainment or interfered in maintenance at the linked receptors for each particular state.

The resulting Proposed Rule imposes limits on NOx emissions that EPA's own analysis acknowledges have never been demonstrated in the iron and steel industry and cannot be met by any technology currently available for use in the iron and steel industry. Many of the technologies proposed by EPA to control NOx (e.g., SCR, SNCR) are not technically feasible for the emission units included under the Proposed Rule. And even if technology used in wholly dissimilar industrial processes (e.g. coal-fired power plants and boilers) were able to be implemented, the costs would be significantly higher than the thresholds EPA relied upon for screening out available control technologies. EPA also assumes that low NOx burners are an available technology for certain emission units to reduce NOx emissions, completely ignoring the fact that many of these units already incorporate low NOx burner technology. Associated production downtimes also would have severe economic consequences for the industry. Furthermore, it is without question that efforts to adapt these technologies to the iron and steel industry would increase emissions of other pollutants and require re-engineering and modifications to not only the steel making process, but also existing air pollution control equipment. Simply put, the addition of ancillary equipment to address flue gas characteristics and the batch nature of the steelmaking process, among other challenges, would necessarily drive up costs and have both upstream and downstream impacts that would not have been accounted for in the original equipment design specifications.

The Proposed Rule also makes assumptions regarding equipment availability and constructability that cannot be reconciled with present and future supply chain considerations and threatens to hamstring the economy and national security with extended downtime or closures and resultant shortages of domestic iron and steel supply.

To justify all the above, the Proposed Rule relies on arbitrary modeling using result-oriented assumptions containing significant errors and omissions, incorrect interpretations of the CAA and legal precedents addressing pollution transport. In short, the Proposed Rule attempts to go well beyond EPA's authority under the CAA. In so doing EPA risks legal challenges to any final rule in the same form as the Proposed Rule that will restrict EPA's discretion in future rulemakings. And because the Supreme Court allows as applied challenges to rulemakings effectuating the Good Neighbor clause of the CAA, EPA's decision to make the Proposed Rule apply on a unit specific basis directly to facilities means that EPA will open the door to as-applied challenges as every covered facility will have the ability to challenge the applicability of the Proposed Rule's limits as applied to that facility, likely jettisoning the uniformity that EPA purports to seek in the Proposed Rule and stringing out any rulemaking in constant challenges.

GENERAL COMMENTS PERTAINING TO THE PROPOSED RULE

I. The Proposed Rule's Attempt to Impose Unit Specific Emission Limits Is Unlawful, Arbitrary, and Not Supported By the Record.

A. EPA Has Identified No Legal Basis for Imposing Emission Unit Specific Limits on Any of the Individual Non-EGU Emission Units the Proposed Rule Purports to Regulate.

The provision of the CAA on which EPA bases this entire regulatory undertaking (a/k/a the "Good Neighbor provision" to the CAA) only grants authority to:

> "prohibit[ ] . . . any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will . . . contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any such national primary or secondary ambient air quality standard"[3]

Thus, when enacting a FIP to satisfy this provision, EPA only has authority to regulate a "source" or "type of emissions activity" if EPA demonstrates that the specific "source" or "type of emissions activity" it proposes to subject to such regulation is actually contributing significantly to nonattainment or interference with maintenance status in a state other than that in which the "source" or "type of emissions activity" is located.

This is the first time EPA has attempted to impose facility-specific emission limits under a "one-size fits all" Federal Implementation Plan based upon the Good Neighbor provision of the CAA. Accordingly, for EPA to have authority to do so under the Good Neighbor provision, EPA must demonstrate that the "source" EPA is prohibiting from emitting above the Proposed Rule's NOx limits is contributing significantly to downwind nonattainment or contributing significantly to downwind maintenance issues. But EPA fails to provide any basis for finding any U. S. Steel facility to contribute significantly to any nonattainment or interference with maintenance.

First, EPA does not define any threshold to evaluate whether a given source's contribution constitutes a significant contribution to downwind linked receptors for purposes of the Good Neighbor provision.[4] Instead, EPA sweeps in states based on a statewide significance threshold of 0.7ppb, identifies industries that on a nationwide basis contribute to downwind nonattainment or

[3] 42 U.S. Code § 7410(a)(2)(D)(i)(I).

[4] As discussed in more detail in another comment below, EPA has in fact established a facility specific significance threshold of 1ppb (i.e., the Ozone SIL) based on an actual statistical analysis of what contribution is capable of showing any modeled effect beyond mere background variation, but the Proposed Rule at no point acknowledges this threshold or prior statistical analysis.

maintenance receptors using a 0.01ppb significance threshold[5], then skips to applying the Proposed Rule's limits to all facilities in all such industries in all covered states without any evaluation of the statutory mandate to consider whether the specific covered "source or other type of emissions activity" will "contribute significantly to nonattainment." Failure to even set a threshold to evaluate source-level contribution significance constitutes a failure to attempt the evaluation required under the statute if EPA wishes to set source-specific emission limits.

Second, the Proposed Rule neglects to perform any source-specific impact analysis to evaluate the impact (or lack thereof) that the specific sources EPA proposes to subject to NOx limits have on any of the identified nonattainment and maintenance receptors. And this failure is not for lack of capacity. The CAMx model EPA relied on for evaluating nonattainment and maintenance receptors has the capability to tag source-level and/or industry-level contributions. As EPA notes, CAMx "employs enhanced source apportionment techniques that track the formation and transport of ozone from specific emissions sources and calculates the contribution of sources and precursors to ozone for individual receptor locations."[6] But the Proposed Rule acknowledges that EPA ignored facility level impacts on downwind-state ozone concentrations, and instead, when using CAMx, only "performed nationwide, state level ozone source apportionment modeling."[7] This failure to evaluate the significance of source specific impacts means that EPA has failed to demonstrate that U. S. Steel facilities it proposes to regulate are in fact linked to any nonattainment or maintenance receptor so as to permit emission reductions under the Good Neighbor provision of the CAA.

To be sure, EPA has not always evaluated source specific impacts on downwind receptors in other states in its prior rulemakings, but that is because those prior rulemakings were fundamentally different than the Proposed Rule. For instance, under the ozone transport rule evaluated by the Supreme Court in *EPA v. EME Homer City Generation, L.P.* 572 U.S. 489 (2014), EPA did not attempt to impose source specific controls or emission limits, but instead created an annual emission "budget" for each state that EPA concluded was contributing significantly to downwind nonattainment and maintenance issues, and then set up an interstate emission trading system within such state allowing covered sources to allocate the emissions and any needed reductions among themselves through purchase and sale of allowances.[8] Under a regulatory program set up in that manner, it may have been rational to impose an aggregated statewide emission limit for NOx from EGUs based on similarities in the sources and a finding at the same

[5] See e.g., Proposed Rule at 20,083 n. 164 (screening the significance of industry contributions using either 0.1ppb at at least one nonattainment or maintenance receptor, or 0.01ppb at at least ten such receptors, but nowhere setting a facility specific significance screening threshold).

[6] Proposed rule at 20,070.

[7] Proposed rule at 20,070.

[8] See 76 Fed. Reg. 48,208; see also EPA, "Fact Sheet: The Cross-State Air Pollution Rule: Reducing the Interstate Transport of Fine Particulate Matter and Ozone" available at https://www.epa.gov/sites/default/files/2016-09/documents/csaprfactsheet.pdf ("The final Cross-State Air Pollution Rule allows sources to trade emissions allowances with other sources within the same program (e.g., ozone season NOX) in the same or different states, while firmly constraining any emissions shifting that may occur by requiring a strict emission ceiling in each state").

level of generality that a state's statewide emissions in the aggregate significantly contributed to downwind nonattainment, and that EGUs were the primary driver (i.e., treating statewide EGU emissions as the "emissions activity" which EPA could "prohibit . . . amounts which will . . . contribute significantly to nonattainment").

Instead, EPA proposes for the first time to use the Good Neighbor provision to impose command-and-control limits at the individual facility level without any justification that the facility (or even the industrial section in the state that it is part of) contributes significantly to downstream nonattainment or maintenance issues. It is one thing for EPA to tell a state that its contribution to nonattainment/maintenance problems in another state is a certain level and then allow a state or the sources therein to allocate reductions needed among themselves to achieve the statewide reductions needed; it is quite another thing to impose specific emission limits directly on a state's sources without any further source level analysis. If EPA wishes to treat individual emission units as the granular level of "source or other emissions activity" from which to "prohibit . . . amounts which will . . . contribute significantly to nonattainment," it must necessarily show that such units "contribute significantly to nonattainment." And EPA has not attempted to do so with respect to any of the non-EGU emission units in the Proposed Rule, let alone for the emission units at U. S. Steel facilities.

B. The Analyses Included in the Record Cannot Support the Source-Specific and State-Specific Impact Findings Required by the Clean Air Act.

EPA has not adequately demonstrated that the individual or category of sources it proposes to regulate under the proposed FIP cause or interfere with ozone attainment or maintenance in downwind states, but instead uses grossly inaccurate assumptions in its analysis and modeling rendering the entire FIP fatally flawed.

The 4-step framework as applied in the Proposed Rule identifies no sources or emissions activities in one state that significantly contribute to downwind air quality problems in another state (as the Good Neighbor provision of the CAA requires). Even for states that are contributing to nonattainment or interfering with maintenance, EPA has established no data to support which non-EGU emission sources within the state are "potentially controllable," would "have the greatest ppb impact on downwind air quality" or be "make meaningful air quality improvements at the downwind receptors at a marginal cost threshold" as EPA's own interpretation of the Clean Air Act dictates.[9] Without this information, EPA's FIP is arbitrary and capricious. *State Farm*, 463 U.S. at 43 (an agency rule is arbitrary and capricious if the agency has "entirely failed to consider an important aspect of the problem, offered an explanation for its decision that runs counter to the evidence before the agency, or is so implausible that it could not be ascribed to a difference in view or the product of agency expertise").

Clean Air Act § 110(a)(2)(D) requires SIPs to contain adequate provisions to prevent "any source or other type of emissions activity within the State" that contribute significantly to NAAQS

[9] Screening Assessment at 2.

nonattainment in another state or interference with maintenance. There has been no attempt to gather or model the source-specific data needed to determine what sources, if any, should be subject to regulation to address interstate transport of NOx. For the Proposed Rule, EPA has conducted a Non-EGU "Screening Assessment"[10] to identify costs and controls, but EPA itself acknowledges that this screening assessment "is not intended to be, nor take the place of, a unit-specific detailed engineering analysis that fully evaluates the feasibility of retrofits for the emissions units, potential controls, and related costs."[11]

EPA has never used such modeling and estimation to impose unit-level emission limits. While EPA points to the screening assessment is used in CSAPR, and which was affirmed by the Supreme Court in *EPA v. EME Homer City Generation, LP*, 572 U.S. 489 (2014), there EPA was allocating state-level emission budgets and was based on "complex modeling to establish the combined effect the upwind reductions projected at each cost threshold would have on air quality in downwind States." *Id.* at 1596.

The record lacks the data needed to impose source-specific emission limits, and EPA has made no effort to develop similar source-specific modeling for non-EGUs. To the contrary, EPA's assessment, while starting with state-specific modeling to identify "linked" states, then proceeds to ignore any state-specific distinctions in evaluating the emission sources that should be subject to regulation. Specifically, after EPA identified "linkages" from a state to a downwind receptor based on as little as a 1% modeled impact on the design value, the Screening Assessment identifies industries that, without regard to those same state linkages, had over an arbitrarily set threshold of either 0.1 ppb impact on a single receptor or as low as a 0.01 ppb impact on at least 10 receptors.[12] The Proposed Rule then, without any technical or legal basis, assumes that, for those industries, every source within the same industry code has a significant contribution or interferes with maintenance and thus is subject to regulation.

Compounding this generalization, the Proposed Rule then assumes that the same controls and the same efficiency, can be achieved at all of these sources, using the same technology, and at the same cost, with no consideration of the size, age, past performance, or any other individual data from any single facility or emission unit.

While EPA could support industry-wide modeling of EGUs as a sufficient basis to impose state NOx budgets in *EME Homer*, the Proposed Rule's attempt to impose source- and emission unit-specific emission limits based on nothing more than generalized assumptions of what various industries that happen to be located in at least one "linked" state is untethered from any attempt to reduce significant contribution to nonattainment or interference with maintenance of the NAAQS and is patently insufficient. EPA cannot impose source and unit-specific emission requirements without first confirming that it screening assumption hold up when applied to the actual states, sources, and emission units that will be subject to regulation. Otherwise, EPA has "entirely failed

[10] Proposed Rule Non-EGU Screening Assessment.

[11] Non-EGU Screening Assessment at 7.

[12] *Id.*

to consider an important aspect of the problem" and "offered an explanation for its decision that runs counter to the evidence before the agency." *State Farm*, 463 U.S. at 43.

C. EPA's Sweeping Pollution Control Generalizations and Assumptions are Unproven and Inaccurate and Cannot Support the Proposed Rule' Emission Limits.

EPA cannot shift its burden to the states and affected sources to prove that its strategy is technologically and/or economically infeasible for each unique source that EPA proposes to regulate by the FIP. Rather, it is EPA's duty to provide "the factual data on which the proposed rule is based" and "the methodology used in obtaining the data and in analyzing the data." 42 U.S.C. § 7607(d)(3).

EPA's record for the Proposed Rule does not support the emissions controls or limits in the Proposed Rule, and in many cases, it contradicts the conclusions in the Proposed Rule. For example, while the Proposed Rule states that the "types of emissions control technologies on which the EPA proposes to base the emissions limitations that would take effect for the 2026 ozone season … generally are intended to be consistent with the scope and stringency of RACT requirements for existing major sources of NO_X" 87 Fed. Reg. at 20,101-102, the emission limits EPA proposes for the iron and steel industry assume, without support that emissions reductions of 25% to 50% can be achieved beyond recently-determined emission limits, including Ohio RACT limits for blast furnaces and reheat furnaces. *Id.* at 20,145, Table VII.C-3. Other limits are based on achieving similar reductions beyond recently established Best Available Control Technology ("BACT") determinations. *See id.*[13][14] The Proposed Rule not only leaves unanswered why emissions are capable of being reduced 40% from a BACT determination made last year, but also how such a limit can be imposed not only on new sources, but on existing sources as well. When the results of EPA's generalized assumptions are emissions limits that radically depart from EPA's own purported basis for establishing them, the adequacy of EPA's data and rationale for the Proposed Rule must be called into question.

EPA's proposed emission limits are also based on unsupported assumptions that pollution controls that have never been demonstrated in the iron and steel industry are feasible and effective—so effective that they will now result in substantial (40%-50%) reductions in emissions beyond current best-performing sources. As just one example, EPA has assumed that selective catalytic reduction ("SCR") is broadly available to reduce emissions from numerous sources,

[13] The Proposed Rule's emission limit for Ladle/tundish Preheaters is based on an assumed 40% reduction from Nucor Kankakee's BACT permit limit, which was issued in 2021. 87 Fed. Reg. 20,145, Table VII.C-3.

[14] Also, U.S. Steel's BRS facility underwent PSD review in 2013 and the new EV facility underwent PSD review in 2021. BACT analyses were submitted with both applications. EPA provided comments on the draft BRS permit in 2013 but did not comment on the 2021 application. In both instances, the application of SCR, NSCR, and other post-combustion controls for EAFs and other units at the facility was eliminated from consideration because the technology is not technically feasible. See e.g., BACT Analysis in support of the U.S. Steel's BRS facility Air Permit Application for Permit 2445-AOP-R0, dated Oct. 11, 2021. Other PSD permits issued to EAFs in recent years, all subject to review and comment by USEPA, reach similar conclusions.

including blast furnaces and basic oxygen furnaces, and coke ovens, to reduce emissions by as much as 50% from currently permitted limits, along or in combination with low-NOx burners. There is nothing in the record to show that SCR has been installed on any of these emission sources, let alone that doing so would result in the emission reductions EPA projects. The only reference appears to be a 2017 article from the Arid Zone Journal of Engineering, Technology and Environment stating that "[t]he combination of low NOX burner (LNB) and Selective catalytic reduction (SCR) is capable of reducing emission for up to 90% and above."[15] The paper does not indicate that this is based on any real-world application, however, and cites only studies of the use of SCR for other sources. EPA's own 2020 assessment for the 2008 Revised CSAPR rule did not consider SCR for the primary metals manufacturing industry.[16] As AISI has also already explained in comments on CSAPR, low-NOx burners were also recently eliminated as a control option for blast furnace stoves fueled primarily by blast furnace gas.[17] Yet EPA proposes to achieve 40-50% reductions at blast furnaces using "burner replacement" for these same stoves.[18]

Similarly, for Taconite Kilns, EPA proposes to assume that low-NOx burners will result in a reduction of 40% of NOx emissions.[19] There is nothing in the record to support this conclusion.

It is EPA's obligation to "examine the relevant data and articulate a satisfactory explanation for its action including a 'rational connection between the facts found and the choice made.'" *State Farm*, 463 U.S. at 43; *see also* 42 U.S.C. § 7607(d)(3) (the statement of basis and purpose must include "the factual data on which the proposed rule is based," "the methodology used in obtaining the data and in analyzing the data," and "the major legal interpretations and policy considerations underlying the proposed rule"). Nonetheless, U. S. Steel has, in the time allowed, identified several inaccuracies and improper assumptions in the feasibility and effectiveness of pollution control equipment for the iron and steel industries, and has documented those findings in the attached reports found in Exhibits A-D.

D. EPA Cannot Proceed to a Final Rule on this Record, Because the Proposed Rule Is Based Upon Many Data Errors, Data Gaps, and Incorrect Assumptions, Which Leave the Rule Insufficiently Supported.

The Proposed Rule is based on a set of vague, nation-wide assumptions about the NOx emissions generated by regulated industries, the relative contributions to downwind receptors, the emissions controls that are available to reduce NOx, the effectiveness of these controls, and cost of installation and operation, and the time required to install and operate them. These broad assumptions are generally not to be found in the record. Where U. S. Steel has painstakingly

---

[15] EPA-HQ-OAR-2021-0668-0050.

[16] EPA-HQ-OAR-2020-0272.

[17] AISI Revised CSAPR Comments at 4.

[18] 87 Fed. Reg. 20,1045, Table VII.C-3.

[19] 87 Fed. Reg. 20,182.

sought to reconstruct EPA's analysis, the results indicate numerous errors and unwarranted assumptions.

U. S. Steel has endeavored to identify as many of these issues as it can in the limited time allowed and has documented these findings in the detailed reports prepared by Woodward and Curran, Black and Veatch, Trinity Consultants and Barr attached with these comments as Exhibits A - D. Prior comments have also identified numerous errors in EPA's emissions data. As U. S. Steel noted in its comments on the SIP denial rule, the emission estimates from other sources, including those in Arkansas, Illinois, Indiana, Ohio and Michigan – and in particular, emissions from the iron and steel sources in those states, are overstated and are inconsistent with prior state submittals. U. S. Steel SIP Comments are attached as Exhibits E & F. The Midwest Ozone Group has noted that numerous exceptional events have been improperly factored into the modeling used by EPA in the Proposed Rule.[20] Lake Michigan Air Directors Consortium (LADCO) has performed a detailed Source Classification Code ("SCC") based analysis of EPA's 2016v2 emissions modeling platform. In doing so, it found EPA's projected emission rates "are not consistent either with real-world emissions trends or regional emissions projection information."[21] The State of Minnesota similarly submitted a list of sources that it believes have incorrect future year projection rates.[22]

More fundamentally, however, EPA cannot proceed with a rule based upon many errors and incorrect assumptions. In order to avoid arbitrary and capricious rulemaking, "the agency must examine the relevant data and articulate a satisfactory explanation for its action including a 'rational connection between the facts found and the choice made.'" *Motor Vehicle Mfrs. Assn. of United States, Inc. v. State Farm Mut. Automobile Ins. Co.*, 463 U.S. 29, 43 (1983) (*quoting Burlington Truck Lines, Inc. v. United States*, 371 U. S. 156, 168 (1962). An agency action is arbitrary and capricious "if the agency has relied on factors which Congress has not intended it to consider, entirely failed to consider an important aspect of the problem, offered an explanation for its decision that runs counter to the evidence before the agency, or is so implausible that it could not be ascribed to a difference in view or the product of agency expertise." *Id.* Here, the rationale provided by the agency is oftentimes completely unsupported by the record. At other times, it is implausible, if not contradicted by the record.

Even if EPA were to reject the state-specific evaluations contained in the numerous SIPs before the agency, a federal implementation plan must be based on an adequate understanding of the regulated emission sources, available controls, and their costs and effectiveness. The rulemaking procedures at section 307(d) of the CAA specifically require that a proposed rulemaking must "include a summary of—(A) the factual data on which the proposed rule is based; (B) the methodology used in obtaining the data and in analyzing the data; and (C) the major legal interpretations and policy considerations underlying the proposed rule" and "All data, information,

and documents referred to in this paragraph on which the proposed rule relies shall be included in the docket on the date of publication of the proposed rule."[23] Furthermore, any final "promulgated rule may not be based (in part or whole) on any information or data which has not been placed in the docket as of the date of such promulgation."[24] Relatedly, EPA has "an initial burden of promulgating and explaining a non-arbitrary, non-capricious rule."[25] The many errors and incorrect assumptions and the many ways explained throughout these comments that the Proposed Rule is not grounded in or adequately related to the modeling and data actually in the regulatory docket demonstrate that the record is simply insufficient to proceed with a final FIP.

II. EPA's Proposed Control Limits Go Beyond Any Level of Control Imposed by EPA, and Conflicts With Prior EPA Determinations.

EPA makes the assertion that the limits imposed by the Proposed Rule on non-EGUs "generally are intended to be consistent with the scope and stringency of RACT."[26] But this stated goal is inconsistent with the approach EPA actually took to setting the limits, and thus in violation of EPA's obligation to promulgate internally consistent rules.[27] In fact, for most (but not all)[28] units, EPA specifically considered RACT limits specified by states, then expressly rejected setting levels consistent with RACT, instead going on to propose limits up to a staggering 50% below the corresponding RACT limits considered.[29] These resulting proposed limits are also stricter than BACT, and inconsistent with recent BACT evaluations, which EPA had opportunity to comment on, which have ruled out SCR, NSCR, and other post-EAF NOx controls as not technically feasible for EAFs.[30] And the limits are even stricter than LAER, given that EPA can identify no new or existing facility nationwide in the industry that has demonstrated these limits in practice, and has identified no grounds for concluding that they may be feasible on an EAF.[31]

[24] Id.

[25] *National Lime Ass'n v. E. P. A.*, 627 F.2d 416, 433 (D.C. Cir. 1980)

[26] Proposed Rule at 20,101-02.

[27] *Hsiao v. Stewar*t, 527 F. Supp. 3d 1237, 1252 (D. Haw. 2021), quoting *Nat'l Parks Conservation Ass'n v. EPA*, 788 F.3d 1134, 1141 (9th Cir. 2015) ("[A]n internally inconsistent analysis is arbitrary and capricious.").

[28] Non-EGU Sectors TSD at 42 (considering RACT for blast furnaces, reheat furnaces, ladle preheaters, annealing and galvanizing furnaces, but not for EAFs).

[29] See e.g. Proposed Rule at 20145 identifying Ohio RACT for blast furnaces at 0.06 lb, then setting a proposed limit at half that level.

[30] See e.g., BACT Analysis in support of the U.S. Steel's BRS facility Air Permit Application for Permit 2445-AOP-R0, dated Oct. 11, 2021.

[31] Notably, although EPA claims to identify an annealing furnace that successfully installed an SCR, EPA does not use that facility as a basis for the emission limits proposed for Annealing Furnaces, further calling into question whether the limits proposed by EPA are even possible in practice. And even if some type of annealing furnace ever installed an SCR, the concept of the application of an SCR on all annealing furnaces could not be justified, for instance some of the annealing furnaces at the U. S. Steel's BRS facility are small units that emit less than 6 tpy and run only intermittently such that they are not even stacked and thus neither CEMS not SCR would be possible to connect.

Furthermore, although EPA requests comment on the appropriateness of simply requiring RACT in states subject to the Proposed Rule,[32] EPA does not claim to have even attempted to model whether RACT might be sufficient to bring any given state's linked downwind receptors into attainment. Instead, EPA states that it "focuses on obtaining emissions reductions from non-EGU units that were quantitatively determined to have the most significant impacts on air quality improvements at the downwind nonattainment and maintenance receptors." [33]

But critically, as explained in more detail throughout these comments, EPA's modeling used to demonstrate statewide emission reductions necessary to reduce downwind emissions to acceptable levels was not based on the limits included in the Proposed Rule. [34] Instead, what EPA actually modeled was as follows: "We re-ran CoST with known controls, the CMDB, and the 2019 emissions inventory. We specified CoST to allow replacing an existing control if a replacement control is estimated to be >10 percent more effective than the existing control. We did not replace an existing control if the 2019 emissions inventory indicated the presence of that control, even if the CMDB reflects a greater control efficiency for that control."[35] Notably, the output tables for this modeling show no reductions required at any EAF, and SCR only being added at certain BOF and Blast Furnaces and boilers.[36] Accordingly, to the extent that the modeling EPA actually performed shows that Good Neighbor provisions are satisfied with less stringent emission reductions, and without any reductions from a single U. S. Steel facility, EPA's choice to nevertheless go further than supported by its modeling and impose the draconian limits more stringent than RACT, BACT, or even LAER necessarily constitutes arbitrary and capricious overcontrol.

Finally, and independently, regardless of the rationality of requiring upwind states to meet RACT, it is certainly unreasonable, unlawful, and inconsistent with both EPA's past practice and court precedent interpreting the Good Neighbor provision to subject upwind states to emission limits that are stricter than the RACT limits imposed in the downwind states. After all, as EPA acknowledged when setting out the prior Good Neighbor framework upheld by the Supreme Court in *EPA v. EME Homer*, "Section 110(a)(2)(D)(i)(I) only requires the elimination of emissions that significantly contribute to nonattainment or interfere with maintenance of the NAAQS in other states; it does not shift to upwind states the responsibility for ensuring that all areas in other states attain the NAAQS."[37] Likewise, the D.C. Circuit's decision in *Wisconsin v. EPA* calls for aligning

[32] Proposed Rule at 20,097.

upwind and downwind requirements to treat them consistently to the degree possible. Accordingly, whatever requirements are placed on upwind industry should not be more stringent than those applicable to industries subject to RACT due to actually being in a nonattainment area; it would be irrational, arbitrary, and capricious, when considering impacts to the same nonattainment or maintenance receptor, to force a source far away to enact stricter limits than a source actually in or next door to the nonattainment area.[38]

III. EPA Fails to Demonstrate that the Proposed Rule Avoids Overcontrol Because The Proposed Rule Fails to Evaluate Alternative Cost Thresholds for Non-EGUs.

EPA claims that the Proposed Rule continues to "apply the same approach as the prior three CSAPR rulemakings for evaluating 'significant contribution' at Step 3" including "evaluat[ing] NOX reduction potential, cost, and downwind air quality improvements available at various mitigation technology breakpoints (represented by cost thresholds)" and states that this approach "was upheld by the U.S. Supreme Court in *EPA v. EME Homer City*."[39] EPA is partially correct. The approach used by EPA in its prior three CSAPR rulemakings was upheld in *EPA v. EME Homer City* (subject to the ability of petitioners to pursue any as-applied challenges based on allegations of overcontrol). But that is not what EPA did in this Proposed Rule.

EPA's approach in the Proposed Rule is crucially different from that upheld by the courts in the past, because here EPA did ***not*** evaluate "NOx reduction potential, cost, and downwind air quality improvements available at various mitigation technology breakpoints (represented by cost thresholds)" with respect to non-EGUs. Instead, as explained below, EPA selected a cost-efficiency threshold for non-EGU controls based solely on total reductions available, instead of setting a cost threshold based on the controls strictly necessary to achieve attainment at downwind linked receptors. Accordingly, the control level selected for non-EGUs is wholly inconsistent with EPA's prior approach, has no basis in prior precedent, and fails to demonstrate that EPA is avoiding overcontrol, particularly since EPA failed to model whether a lower cost threshold for non-EGUs sources may also have achieved attainment at downwind receptors.

In the *EME Homer* CSAPR litigation, the Supreme Court approved an approach of modeling the reductions associated with several different cost thresholds of potential controls, and setting the cost threshold (and thus controls) at the lowest level needed to achieve attainment in downwind receptors.[40] But here, EPA set a cost threshold for non-EGUs based on the maximum

[38] Note that the stringency of controls is conceptually distinct from the amount of emissions reductions. If a given level of control on whatever industry most contributes to a downwind linked nonattainment or maintenance receptor is insufficient to fulfil a state's Good Neighbor obligation (something EPA has not demonstrated since EPA has not yet either modeled the highest industry contributors on a state by state basis, or accurately modeled the level of controls proposed in the rule), then the applicability of the controls can be extended to additional sources or industries, rather than requiring a specific industry to be more tightly controlled in an upwind state than RACT would require in the downwind state.

[39] Proposed Rule at 20,055.

[40] *EPA v. EME Homer City Generation, L.P.*, 572 U.S. 489, 500 (2014) ("Under the Transport Rule, EPA employed a 'two-step approach' to determine when upwind States 'contribute[d] significantly to nonattainment,' and therefore in 'amounts' that had to be eliminated. At step one, called the 'screening' analysis, the Agency excluded as de minimis

amount of emission reductions potentially achievable (rather than based on the amount needed to resolve downwind receptors), and only modeled controls at that cost threshold ($7,500) without ANY modeling to see if incrementally lower cost thresholds could also achieve attainment at downwind receptors.[41]

Notably, EPA's use of cost thresholds in the Proposed Rule was radically different for EGUs and non-EGUs. The Proposed Rule's support documents do consider several incremental cost thresholds for EGUs in creating modeling scenarios, ranging from $1,600 to $11, 000. But for non-EGU's, EPA instead:

1. aggregated all proposed industries together, instead of setting industry specific cost thresholds like EPA did for EGUs;
2. selected only a single control scenario for consideration (i.e. all controls up to $7,500/ton) rather than the many control levels modeled for EGUs; and
3. rather than varying the level of controls required to reduce emissions from a set list of significant facilities (like the rule does for EGUs), for non-EGUs, the only modeling variations run by EPA were changing which units a preordained level of controls would be applied to.

As explained in the Policy Analysis TSD, only the following scenarios were modeled for their effect on ppb ozone concentrations at downwind receptors:[42]

- Engineering Analysis Base
- EGU only $1,600 cost threshold (SCR Optimize + Generation Shifting)
- EGU only $1,600 cost threshold (SCR Optimize + SOA CC + Generation Shifting)
- EGU only $1,800 cost threshold (SCR Optimize + SNCR Optimize + Generation Shifting)

---

any upwind State that contributed less than one percent of the three NAAQS to any downwind State 'receptor,' a location at which EPA measures air quality. . . The remaining States were subjected to a second inquiry, which EPA called the 'control' analysis. At this stage, the Agency sought to generate a cost-effective allocation of emission reductions among those upwind States 'screened in' at step one. The control analysis proceeded this way. EPA first calculated, for each upwind State, the quantity of emissions the State could eliminate at each of several cost thresholds. . . . The Agency then repeated that analysis at ascending cost thresholds. Armed with this information, EPA conducted complex modeling to establish the combined effect the upwind reductions projected at each cost threshold would have on air quality in downwind States. The Agency then identified 'significant cost threshold[s],' points in its model where a 'noticeable change occurred in downwind air quality, such as . . . where large upwind emission reductions become available because a certain type of emissions control strategy becomes cost-effective.' For example, reductions of NOX sufficient to resolve or significantly curb downwind air quality problems could be achieved, EPA determined, at a cost threshold of $500 per ton (applied uniformly to all regulated upwind States).") (internal citations omitted).

[41] Proposed Rule at 20083; see also Non-EGU Screening Assessment at 4.

[42] See Policy Analysis TSD at 55-57, Tables C-12, C-13, and C-14.

- EGU only $1,800 cost threshold (SCR Optimize + SOA CC + SNCR Optimize + Generation Shifting)
- EGU only $11,000 cost threshold (SCR Optimize + SOA CC + SNCR Optimize + SCR/SNCR Retrofit + Generation Shifting)
- EGU $11,000 cost threshold plus non-EGU Tier 1 at $7,500 cost threshold (SCR Optimize + SOA CC + SNCR Optimize + SCR/SNCR Retrofit + Generation Shifting + non-EGU Tier 1)
- EGU $11,000 cost threshold plus non-EGU Tiers 1&2 at $7,500 cost threshold (SCR Optimize + SOA CC + SNCR Optimize + SCR/SNCR Retrofit + Generation Shifting + non-EGU Tier 1 + Tier 2)

Accordingly, as noted above, although different cost thresholds were evaluated for EGUs, *EPA never modeled the effect of different cost thresholds for non-EGUs*. Likewise, the "less stringent" and "more stringent" scenarios evaluated in the Regulatory Impact Analysis for non-EGUs only vary the scope of units evaluated, with the less stringent scenario subjecting fewer units to the Proposed Rule, and the more stringent scenario subjecting all Tier 1 and 2 units to the Proposed Rule regardless of their size, but all such scenarios assumed the same cost threshold for level of controls for all non-EGU regulatory scenarios.[43] Thus EPA has not demonstrated that the selected control efficiency of $7,500 per ton for non-EGUs avoids overcontrol, as compared to some lesser cost threshold (e.g. reflecting solely combustion controls like low-NOx burners and optimizations, without post combustion SCR retrofits), since EPA failed to model the effect of any lesser cost thresholds for non-EGUs.

This failure to model alternate cost scenarios is particularly untenable given that EPA's own cost modeling clearly showed that Tier 1 industries like Iron and Steel manufacturing had a "knee in the curve" at $1,000, and not the $7,500 threshold selected by EPA, as discussed below in the section regarding cost of controls.[44]

Because EPA failed to model the impact of control scenarios for non-EGUs associated with any lower cost threshold, the EPA has failed to demonstrate that the cost threshold chosen represents the lowest level of necessary controls that will "only limit emissions 'by just enough to permit an already-attaining State to maintain satisfactory air quality.'"[45]

[43] See Regulatory Impact Analysis at ES-7.

[44] See non-EGU Screening Analysis at 4, showing different cost-effective thresholds for Tier 1 and Tier 2 industries, but then ignoring this clear data and only evaluating the aggregate $7,500 cost threshold.

[45] *EME Homer City Generation, L.P. v. E.P.A.*, 795 F.3d 118, 137 (D.C. Cir. 2015) (quoting *EPA v. EME Homer City Generation, L.P.*, 572 U.S. at 515 n.18).

IV. EPA Fails to Demonstrate that the Proposed Limits and the Theoretical Controls They are Based on Are Technically Feasible at the Facility and Unit Specific Level.

It would be arbitrary and capricious to require something that is not possible.[46] Yet, as explained in more detail below, the Proposed Rule would impose limits on iron and steel emission units below what have ever been achieved in the industry, based on little more than speculation about feasibility of controls that have never been demonstrated in practice in the industry. And in any case, EPA must show more than bare possibility to justify the emission limits in the Proposed Rule. Congress has made the express determination that "reasonably available control technology" (RACT) is the appropriate level of control when addressing even nonattainment areas themselves.[47] And it would be arbitrary and inconsistent with the scheme of Title I and intent of Congress for sources in upwind states to be subject to limits stricter than the RACT limits applicable within nonattainment areas. In interpreting this standard, EPA has consistently found that "RACT for a particular source continues to be determined on a case-by-case basis considering the technological and economic feasibility of reducing emissions from that source."[48] In evaluating technical feasibility EPA must evaluate, on a facility and emission unit specific basis, "the source's process and operating procedures, raw materials, physical plant layout, and any other environmental impacts such as water pollution, waste disposal, and energy requirements" "the operation of and longevity of control equipment" "the space available in which to implement such changes" and "Reducing air emissions may not justify adversely affecting other resources by increasing [other types of] pollution" or "creating excessive energy demands."[49] Accordingly, EPA is correct to speak throughout the Proposed Rule about whether the controls proposed are "feasible" and "appropriate,"[50] but EPA must do more than talk about appropriateness, EPA must demonstrate that the proposed limits are both technically and economically feasible on a facility specific basis. This EPA has not done, and the Proposed Rule is unlawful without doing such analysis. And in any case, EPA has an independent "duty to examine [and justify] key assumptions as part of its affirmative 'burden of promulgating and explaining a non-arbitrary, non-capricious rule. . . .'"[51] and EPA may not "promulgate rules on the basis of inadequate data, or on data that,

[46] Notably even EPA relies on not being required to achieve the impossible. See Proposed Rule at 20062 ("implementing good neighbor obligations beyond the dates established for attainment may be justified on a proper showing of impossibility or necessity.").

[47] 42 U.S. Code § 7502; see also State Implementation Plans; General Preamble for the Implementation of Title I of the Clean Air Act Amendments of 1990; Supplemental, 57 Fed. Reg. 18,070, 18,073 (April 28, 1992).

[48] State Implementation Plans; General Preamble for the Implementation of Title I of the Clean Air Act Amendments of 1990; Supplemental, 57 Fed. Reg. 18,070, 18,073 (April 28, 1992).

[51] *Appalachian Power Co. v. EPA*, 328 U.S. App. D.C. 379, 135 F.3d 791, 818 (1998).

to a critical degree, is known only to the agency."[52] And thus EPA's assumptions regarding feasibility in the Proposed Rule must be adequately justified, yet, as explained in more detail in later sections herein specific to different types of U.S. Steel's operations, EPA has not done so.

V. EPA's Cost Analysis is Not Reasonable

As noted elsewhere in these comments, EPA must consider economic feasibility in setting control measures under RACT, the standard Congress has specified as applicable to NAAQS nonattainment areas.**53** EPA does have some discretion when setting cost effectiveness thresholds in rulemaking proceedings. But, "the law does require EPA to 'cogently explain why it has exercised its discretion in a given manner.'"[54] Furthermore, although EPA is entitled to make assumptions in its cost analyses, it has a "duty to examine [and justify] key assumptions as part of its affirmative 'burden of promulgating and explaining a non-arbitrary, non-capricious rule. . . .'"[55] EPA may not "promulgate rules on the basis of inadequate data, or on data that, to a critical degree, is known only to the agency."[56] EPA's approach to cost estimates and cost thresholds in the rule violate these principles and/or makes unreasonable assumptions and conclusions in a variety of ways as explained below.

A. EPA's Ignores High Variability of SCR Retrofit Costs

EPA acknowledges that its cost estimates are averages, and not reflective of individual facility retrofit costs. [57] But EPA does not address its historic acknowledgment that SCR retrofit costs are highly variable on a facility-by-facility basis making it inappropriate to apply an industry average cost threshold to all facilities in an industry outside of an emission trading program.

In prior Good Neighbor rulemakings, when commenters pointed to the high variability in cost as a critique of EPA's consideration of SCR as an available retrofit technology, EPA acknowledged high variability of SCR retrofit costs, but replied that such variability was not an issue because the emission trading scheme imposed in such prior regulatory regimes "incentivizes emission reductions at units where they are cheapest" and allowed for a choice between installing the controls, or purchasing emission credits such that reductions need not be done at facilities with high retrofit costs.[58] That rationale does not apply here. EPA expressly rejects an emission trading

[57] Proposed Rule at 20,090.

[58] EPA Response to Comments to the Revised Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS, pg. 98.

scheme for non-EGUs. Instead, under the command-and-control scheme adopted by EPA in the Proposed Rule, all impacted non-EGU emission units, particularly in the iron and steel industry subcategory, are essentially required to install SCRs regardless of the site-specific costs. EPA cannot continue to rely on an industry average cost to find SCR as categorically cost effective as EPA attempts to do in the Proposed Rule.

B. Cost Estimates Inaccurately Assume Year-Round NOx Reductions.

EPA's cost-per-ton reduction calculations are unreasonably skewed because they assume that SCR will be run all year at facilities that install it and calculates expected cost per ton on the basis of annual tons of NOx reduced, despite the fact that the NOx emission reductions being sought by EPA in the Proposed Rule are only to address ozone season emissions. For instance, EPA estimates that selection of SCR in the iron and steel industry may be associated with 948 ozone season NOx reductions, at an annual cost of $9,886,092. [59] If EPA had calculated the cost per ozone season ton of NOx reduced, this would result in an estimate of $10,428 per ton of NOx reduced[60] (notably above the cost threshold of $7,500 set by EPA). But EPA instead, without justification, lists the average cost per ton as $4,345[61], which would only be the case if the ozone season tons were extrapolated to assume continuous annual reductions.[62]

This is erroneous both legally and factually. As a legal matter, EPA only has authority to reduce ozone season emissions under the Proposed Rule and thus should limit itself to assessing the cost of ozone season reductions. Furthermore, as a factual matter, facilities will not operate SCR during the non-ozone season as EPA has acknowledged in the Proposed Rule in "quite typical" in the context of EGUs.[63] There are sound technical, economic, and environmental reasons for not operating SCR outside the ozone season, particularly due to the O&M cost associated with operation of the SCR, and in order to attempt to extend the life of the catalyst given the high cost of replacing the catalyst and how quickly the catalyst can be deactivated under the process characteristics of iron and steel furnaces such as BOFs and EAFs, as discussed above, if it were run continuously. For both independent reasons, costs estimates should instead account for the cost per ozone season ton reduced. (which is in many cases higher than the $7,500/ton screening threshold set by EPA even using EPA's own cost estimates).

C. Improper Aggregation of Industries in Setting Effective Control Cost Threshold

EPA's selection of a $7,500 cost threshold for selecting applicable controls was skewed high by grouping all Tier 1 and 2 industries together without justification. As shown in the below

[59] See Non-EGU Screening Assessment at Table 9.

[60] $9,886,092 / 948 = $10,428.

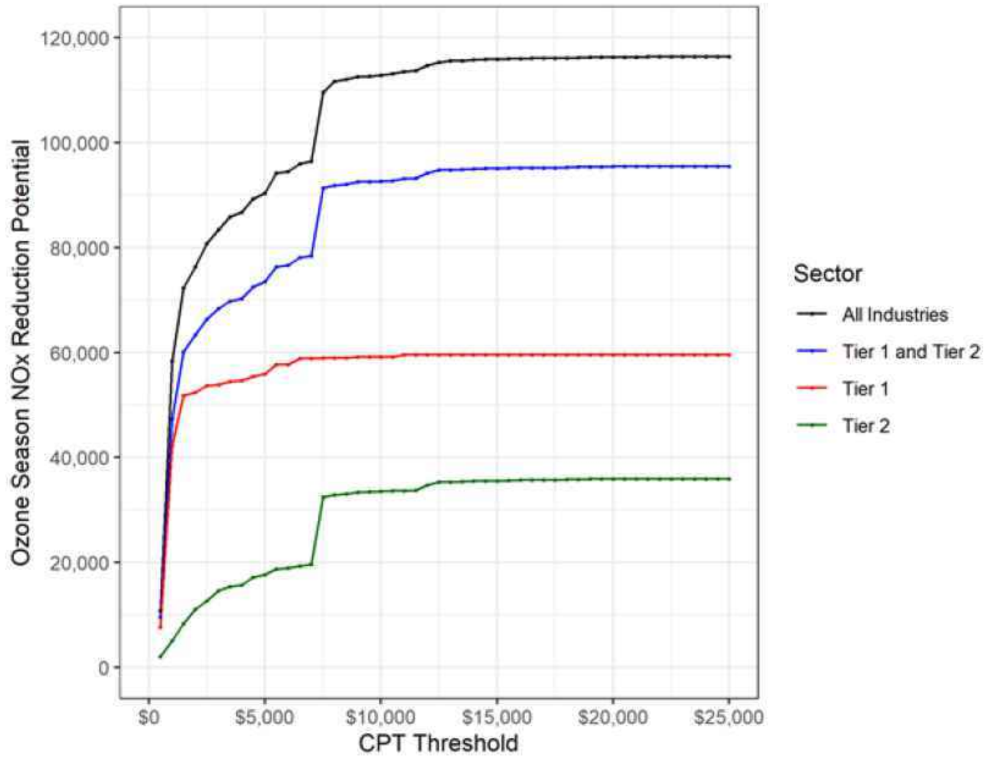
[61] See Non-EGU Screening Assessment at Table 9.

[62] $9,886,092 / (948 X (12 / 5)) = $4,345.

[63] Proposed Rule at 20,078 & n.146.

figure, EPA's cost modeling clearly showed that Tier 1 and 2 industries each had a significantly different "knee in the curve" (i.e. a significantly different cost effectiveness threshold).[64]

Figure 1. Ozone Season NOx Reductions and Costs per Ton (CPT) for Tier 1, Tier 2 Industries, and Other Industries



Based on the above chart, Tier 1 industries had a "knee in the curve" at $1,000 per ton, far lower than the cost effectiveness threshold of approximately $7,500 for Tier 2 industries. Accordingly, because this model showed that cost effectiveness could differ by industry, and because EPA conducted industry specific cost modeling for the EGU industry, EPA should have estimated industry specific cost effectiveness thresholds. But in any case, it was arbitrary for EPA to aggregate these cost curves without any explanation and thus subject all non-EGU industries to the $7,500 cost effectiveness threshold despite EPA modeling affirmatively showing that threshold was not even remotely accurate for Tier 1 industries.

VI. Modeling Problems

The modeling used in support of the Proposed Rule included many questionable and unreasonable assumptions and processes. The sections below summarize many such issues, but the attached report from Woodard and Curran includes more detailed and technical critiques of the modeling underlying the rule which EPA must consider, and which is hereby incorporated by reference.

[64] Non-EGU Screening Assessment at Figure 1.

A. Low Precision/Accuracy:

As discussed in more detail in the attached Woodard report, EPA compared the CAMx model used by EPA to evaluate state contributions to linked receptors with actual monitoring data for each such receptor to evaluate the accuracy and precision of the CAMx model. For example, the result showed a standard deviation of 8ppb for modeling at the relevant Brazoria County, Texas receptor, [65] and only accounted for 37% of observed variation at the receptor. Although EPA claims this is on par with other CAMx models so as to not invalidate use of CAMx for the Proposed Rule, the imprecision of the CAMx modeling should be taken into account when EPA sets its levels of what contribution amount to consider to be "significant" for purposes of determining the applicability of the Proposed Rule. Given that the standard deviation for any CAMx prediction at the Brazoria receptor was up to 8pbb, it is not reasonable or rational for EPA to rely on CAMx to make finetuned distinctions between industries modeled to have impacts at 0.01ppb (the screening level selected by EPA for industry significance), since EPA's own analysis shows that the model is simply not precise enough to statistically differentiate between 0.01ppb, 0.1ppb, and 1ppb. Furthermore, EPA's communications discussed in the attached Woodard report demonstrate that EPA was aware of model "noise" due to model outputs being copied and handled over multiple operating systems and that numerical noise in model outputs could be present and could contribute to variations in modeled concentrations. If that noise was on the order of 0.01 ppb, that would be yet another reason that the modeling could not be relied on to differentiate between impacts at that level of granularity, and thus that such a level below background "noise" cannot be considered significant. Accordingly, EPA should base any determinations of modeled significance at a precision no smaller than 1pbb, so as to at least be within the same order of magnitude as the model's standard deviation.

B. False Geographic Equivalence:

EPA modeled percent reductions needed across each state as if reductions in one part of the state had the same effect as another, rather than modeling how reductions at particular sources affect the NAAQS compliance in downwind states.[66] EPA may have been able to do this under past rules which merely set statewide budgets and did not impose emission unit specific emission limits applicable on a facility level. But if EPA continues to propose facility and unit specific limits, then (as explained in Sections I, IV and XIV regarding EPA authority to issue emission unit limits applicable at a facility level) EPA must model whether such facility has an impact sufficient to justify regulating them under the Good Neighbor clause, rather than the individual limits applicable here. This is particularly true given the fact that CAMx can be used to predict facility level impacts, and EPA simply chose to run the model without that available parameter.

[65] See excel chart labeled "CAMx 2016v2 MDA8 O3 Model Performance Stats by Site".

[66] Policy Analysis at 33 n. 41.

C. Disregard of Emission Increases:

As described in the section herein concerning feasibility of SCR installation, the temperature operating range of an SCR does not match the temperature range needed for the safe and effective operation of a baghouse, such that even if it were technically feasible to install, it would likely require increasing the source's NOx, VOC, PM, SO2, CO, ammonia and greenhouse gases and other pollutants due to the need for additional natural gas and electricity needed to heat, cool, or clean up the flue gas to make it amenable to operable SCR temperature ranges and tolerances. EPA appears not to have accounted for this emission increase (or at least offset against any expected reductions). This in turn will also require analysis of whether increased VOC, PM, NOx, CO, ammonia, etc. emissions as a result of installing SCR would have an adverse effect on compliance with other NAAQS.

D. Ignoring Emission Reductions in Favor of Overcontrol:

As noted above, the model appears to significantly underpredict emission reductions associated with the Proposed Rule, by not even attempting to include all facilities subject to the Proposed Rule or attempting to quantify the actual reductions resulting from the emission limits in the Proposed Rule. This is important to correct before issuing a final rule because ignoring emission reductions resulting from the Proposed Rule would lead to impermissible overcontrol by setting limits that reduce emissions by far more than EPA has modeled are necessary to result in attainment (especially with respect to the Brazoria County, Texas receptor). Accordingly, if EPA intends to proceed with implementing unit specific control emission limitations, EPA must either redo the overcontrol analysis using estimated reduction estimates based on the emission limits proposed in the Proposed Rule, and/or EPA must make the limits less stringent so as to match the statewide emission reductions modeled to not result in downwind attainment without overcontrol.

E. Erroneously Assuming Linear Impacts:

EPA assumed impacts were linear between emission reductions and ppb reductions at receptors, even though EPA acknowledged they are not in fact linear.[67] Although EPA attempted to account for the nonlinear relationship by applying an adjustment factor that is specific to the state and receptor, such adjustment factors do not account for different locations of emission sources within a given state and thus do not adequately correct the erroneous assumption of linear reductions. This is particularly problematic with respect to the U. S. Steel's Arkansas facility, since it is on the far opposite side of the state from the Brazoria County, Texas receptor, yet EPA's adjustment factors treat any reduction at U. S. Steel's Arkansas facility the same as NOx sources in places like Texarkana and El Dorado which are hundreds of miles closer to the Brazoria receptor. Moreover, EPA fails to provide any rationale for why it is accurate or reasonable to apply the same adjustment factor for these geographically remote locations to correct EPA's admittedly erroneous assumption regarding linearity of impacts in relation to emission reductions. Finally, the HYSPLIT modeling conducted by Woodard & Curran and discussed below in Section

[67] Policy Analysis at 33 n. 42.

XIV. of these comments shows that it is important to differentiate between effect of impacts in different portions of the state, because EPA's assumptions of linearity regardless of location in the state is contradicted by the back-trajectories modeled by HYSPLIT, demonstrating that the U. S. Steel's Arkansas facility is not linked to ozone high days at the Brazoria receptor.

F. Mismatch Between Modeled Reduction and Proposed Controls:

EPA's modeling does not accurately reflect the control efficiencies EPA assumes (and requires) in the Proposed Rule. For instance, it appears that EPA performed a modeling run where EPA assumed emission reduction of 30% across all covered sources to demonstrate attainment status at nonattainment and maintenance receptors, and a model run based on the statewide emission reductions EPA expected based on the non-EGU screening assessment. But neither of these modeling runs reflect the emission standards that EPA actually proposes. As previously noted, the modeling run based on the non-EGU screening assessment significantly undercounted emission reductions associated with the Proposed Rule limits. And the modeling run assuming across the board reductions of 30% likewise does not match the limits in the Proposed Rule, which assume unit specific limits far more stringent than 30% in many cases. For EAFs, for instance, "EPA based the emission limit of 0.15 lb/ton of steel on projected reduction efficiency of 40-50% as compared to existing permit limits for EAFs".[68] EPA cannot haphazardly model one set of assumptions and then propose something totally different. EPA should conduct modeling that actually reflects the rule being proposed.

G. Improper Significance Screening Threshold

It is unreasonable for EPA to depart from its August 2018 memorandum regarding determinations of state significant contribution thresholds by now requiring evaluation in light of a 0.7 ppb significance threshold rather than the 1 ppb significance threshold approved in the August 2018 memo.

In the first place, EPA's August 2018 memo provided modeling to support the conclusion that a 1 ppb threshold is generally comparable to a 1% threshold for the 2015 ozone NAAQS in terms of the contributions it would cover, and it is arbitrary for EPA to abandon that conclusion without performing any technical analysis to suggest that EPA's prior conclusion is flawed, or even retracting the August 2018 memo.

Second, 1 ppb is the significant digit for reporting ozone monitoring data under the NAAQS.

Third, the imprecision of EPA's modeling (as discussed above) demonstrates that a significance threshold below 1 ppb simply cannot be justified since the model lacks the capability to distinguish impacts below that level.

[68] Non-EGU Sectors TSD at 43.

Finally, EPA has already determined that 1ppb represents the level at which a single facility presents a significant impact under the 8 hr Ozone NAAQS in the context of PSD permitting.[69] In making the determination that 1ppb represents the significant impact level (SIL) for evaluating whether a given source may contribute significantly to any attainment issues with the 8 hr Ozone NAAQS, EPA engaged in actual statistical analysis to find what "degree of change in concentration is, thus, indistinguishable from the inherent variability in the measured atmosphere and may be observed even in the absence of the increased emissions from a new or modified source" and determined that "changes in air quality within this range [i.e., the relevant SIL] are not meaningful, and, thus, do not contribute to a violation of the NAAQS."[70] By contrast, EPA provides no analysis for why the various proposed significance screening levels in the Proposed Rule (0.7ppb for an entire state, and 0.01 for an entire industrial sector) represent a significant contribution with respect to air quality at downwind receptors.[71]

EPA bases its significance level for statewide emissions on consistency with past CSAPR rulemakings.[72] To be sure, such prior rulemakings also used 1% of the relevant NAAQS as a screening threshold for screening out states without any significant contribution, and that threshold was upheld in 2014 by the Supreme Court in *EME Homer*. But crucially, the past rulemakings EPA points to and the Supreme Court's decision in *EME Homer* all pre-date EPA's 2018 publication of the Ozone SIL and associated modeling and express finding that any contribution under 1ppb is indistinguishable from background variability and thus cannot be characterized as a significant contribution. EPA cannot simply ignore its own more recent modeling and determinations with respect to the 8hr Ozone NAAQS simply by saying it wishes to be consistent with assumptions made before the SIL analysis and determinations were made by EPA. EPA must at minimum explain why it is concluding that a level may constitute a significant contribution that EPA has previously determined by statistical analysis to *not* be significant.

EPA bases its significant contribution threshold for all non-EGU industries on an eyeballed review of a figure comparing relative impacts of different industries, and EPA concludes based on subjective review that "perhaps 0.05 ppb or 0.01 ppb could serve as breakpoints in the data" but ultimately selects 0.01 ppb as "a meaningful conservative breakpoint for screening out non-impactful industries."[73] This analysis is flawed for multiple reasons. First, in selecting 0.01 pbb, EPA asked the wrong question, namely, "what are we confident is so de-minimis as to be

[72] Proposed Rule at 20,074.

[73] Non-EGU Screening Assessment at 22-23.

justifiably screened out" rather than the question posed by the statute, i.e., "what is significant enough to constitute a significant contribution." Although it is justifiable to screen out any industry with impacts below 0.05 or 0.01 pbb impacts to downwind nonattainment and maintenance receptors, that does not mean that it is reasonable to automatically assume that anything above that level is a significant impact. Even more importantly, EPA's subjective comparison of industries to each other can at most only answer the question "what industries are more significant than other industries" and not the statutory question of what "amount" of emissions constitutes a "significant contribution" to downwind receptors. Actually, demonstrating what impact constitutes a significant contribution instead requires statistical analysis evaluating the variation in the Ozone 8-hour design value at each monitoring site, to prove that 0.01 ppb is indeed a threshold above which out of state NOx emissions could significantly impact Ozone attainment, something EPA has not attempted here. In any case, it is arbitrary for EPA to conclude 0.01 ppb from an entire industry can constitute a significant contribution to downwind receptors without even addressing EPA's prior statistical analysis concluding that any amount below 1ppb from even an individual facility is "not meaningful" and so insignificant as to be "indistinguishable from the inherent variability" at downwind receptors and "not contribute to a violation of the NAAQS."

H. Failure to do Any Backtrajectory Modeling or Otherwise Evaluate Consistency and Persistence of Impacts Predicted in CAMx

The model used by EPA (CAMx) only looks at five to ten elevated ozone days in forming its conclusions regarding state contributions to linked predicted nonattainment and maintenance receptors. Due to the complexity of the subject matter, it is questionable whether this small sample size reasonably reflects consistency of predicted contributions. In any case, because EPA does not evaluate consistency and persistence of the impacts found, EPA should have performed some other backtrajectory modeling, such as HYSPLIT, to confirm what geographic regions were contributing to days predicted to be over the NAAQS. At a minimum this should have been performed for Arkansas and Mississippi which were linked to only a single downwind maintenance receptor, to evaluate what sources and geographic areas could be contributing to these predicted high-ozone days, and whether any impact on the maintenance receptor is truly consistent and persistent enough to be classified as a significant contribution. After all, it would not be reasonable to consider an inconsistent or transient effect a "significant contribution." Notably, EPA itself used HYSPLIT in this rulemaking to evaluate environmental justice impacts on a facility specific level for EGUs[74] (though EPA did not use it to evaluate EPA's authority to regulate individual facilities under the Proposed Rule in the first place). EPA has also previously approved the use of HYSPLIT to screen out areas in the similar context of regional haze.[75]

Because EPA failed to perform the modeling needed to assess the significance of state and facility contributions to downwind receptors in the first instance, and because it bears directly on EPA's authority to regulate facilities and states at all under the Good Neighbor provision, EPA

[74] Policy Analysis TSD at 67.

[75] 87 Fed. Reg 7734 (Feb 10, 2022).

must consider any such CAMx or HYSPLIT modeling whenever it is completed in determining applicability of any final rule.

I. Elimination of "Well Controlled Sources"

EPA makes the cryptic observation that it "well-controlled sources that still emit > 100 tpy are excluded from consideration" as part of the modeling related to the non-EGU Screening Assessment, including compliance costs and the emission reductions required in order to meet Good Neighbor obligations.[76] EPA does not explain how a source was determined to be "well controlled" enough to be excluded, and in any case, because EPA expressly set the emission limits in the Proposed Rule below anything EPA found that any emission unit in the iron and steel industry currently achieved. Notwithstanding, any so-called "well controlled" source EPA eliminated from analysis must still have been above the Proposed Rule limits. Accordingly, EPA must explain why sources were excluded from analysis as "well controlled" despite presumably not being well controlled enough to meet the limits EPA now proposes. Although EPA enjoys flexibility in how to perform modeling, it has a "duty to examine [and justify] key assumptions as part of its affirmative 'burden of promulgating and explaining a non-arbitrary, non-capricious rule. . . .'"[77] and EPA may not "promulgate rules on the basis of inadequate data, or on data that, to a critical degree, is known only to the agency."[78]

J. Internal Inconsistency Regarding Anticipated Reductions

The Proposed Rule contains many internal inconsistencies regarding the extent of reductions assumed by EPA in performing modeling and setting proposed emission limits. For example, just with respect to EAFs, the rule Proposed Rule states that it "[a]ssumes 25% reduction by SCR," whereas the Non-EGU Sectors TSD states that it projects "efficiency of 40-50% as compared to existing permit limits for EAFs" and "minimally 40% NOx reduction efficiency is achievable by use of low-NOx technology, including potential use of low-NOx burners and selective catalytic reduction."[79] And the Non-EGU Screening Assessment estimated no reductions from EAFs.[80] In order to draft a non-arbitrary rule, EPA must make a consistent assumption about the emission reductions associated with the Proposed Rule, and actually use that same assumption when modeling costs, feasibility, and air quality impacts at downwind receptors.

K. Use of AEO Rather Than Current Emission Inventories

When describing the non-EGU emission inventory development used in the air quality modeling to identify nonattainment and maintenance areas and the significance of state contributions thereto, the Proposed Rule states that EPA started from the 2016v2 platform, then

---

[76] Proposed Rule at 20,083.

[78] *Portland Cement Ass'n v. Ruckelshaus*, 158 U.S. App. D.C. 308, 486 F.2d 375, 391-93 (1973).

[79] Non-EGU Sectors TSD at 43.

[80] Non-EGU Screening Assessment at Table 6.

"The future year non-EGU point inventories were grown from 2016 to the future years using factors based on the AEO 2021 . . ." [81] But AEO 2021 does not appear to be an industry emissions inventory, but instead only appears to track energy consumption in various industries.[82] It is not reasonable to use this approach when EPA had actual emission inventories (such as the 2019 NEI) available, particularly for EAFs. Unlike EGUs, whose emissions might be expected to strongly correlate to energy consumption at the plant, EAFs NOx emissions are not primarily driven by by the combustion of fossil fuels. Thus, EPA should compare actual updated emission inventories with the AEO to demonstrate its accuracy and appropriateness as a basis for developing emission inventories.

VII. The Proposed Rule Runs Afoul of Many Legal Doctrines:

A. Major Questions Doctrine:

Multiple aspects of the Proposed Rule implicate the major questions doctrine which provides that agencies cannot unilaterally resolve questions of "vast economic or political significance" unless Congress has unambiguously authorized it to do so.[83]

1. The Proposed Rule would mandate generation shifting in the EGU sector in many ways, first, EPA sets emission budgets for EGUs based on assuming that generation shifting will occur, [84] which is a form of expressly requiring generation shifting, by setting limits too low to achieve in the absence of generation shifting. Second, EPA further forces generation shifting through the creation of the "backstop daily rate for large coal EGUs"; which would only apply to coal fired plants, and not natural gas plants,[85] and are expressly designed to make coal fired EGUs, but not natural gas fired EGUs, either "retrofit [with SCR] or retire."[86] This solely targets coal in order to reshape the energy sector to EPA's preferences, in a similar manner to that at issue in the challenges to the Affordable Clean Energy and Clean Power Plan rules. The Supreme Court has accepted review of a set of cases challenging those rules, arguing that the major questions doctrine prohibits EPA from forcing generation shifting or otherwise restructuring the nation's energy system.[87] A decision is expected by June 2022, and any final rule must account for and comply with any interpretation of the major questions doctrine in that case.
2. The Proposed Rule's historically unprecedented use of the Good Neighbor provision to impose emissions limits on a unit specific basis for entire industries, without any

[86] Regulatory Impact Analysis for Proposed Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standard, at ES-7.

[87] See West Virginia v. Environmental Protection Agency, No. 20-1530, and linked cases.

consideration of unit specific feasibility or demonstration that the source itself is contributing to any nonattainment or maintenance site also runs afoul of the major questions doctrine. The text of the Good Neighbor provision, which focuses only on limiting amounts of emissions significantly contributing to actual nonattainment of maintenance issues in downwind states does not clearly authorize the vast industry shaping and reorganizing that EPA attempts to issue in the Proposed Rule.

B. Chevron Doctrine

Multiple aspects of the Proposed Rule exceed the discretion granted to EPA under the statutory text, and thus will not be protected by *Chevron* deference,[88] and may serve as a basis for challenges to *Chevron* itself, or at least to further limits on EPA's deference under *Chevron*.

1. The Proposed Rule only applies by virtue of EPA's disapproval of various SIP plans. In disapproving those state plans (which is a statutory prerequisite for EPA authority to issue the Proposed Rule) EPA effectively asserted that it would prefer to institute a FIP as opposed to individual SIP demonstrations due to a wish to address ozone transport in a "nationally uniform approach" with "nationwide scope and effect" based on a "common core of nationwide policy judgements."[89] But EPA lacks discretion to decide that regional ozone transport is a national problem that requires national uniformity (e.g. by setting industry wide emission limits based on a "common core of nationwide policy judgements" without regard to state specific contribution considerations). Congress already unambiguously made a contrary decision by making EPA's discretion to implement a FIP subject to SIP submissions that EPA "shall" approve if the statutory elements are met. *See* 42 U.S.C. § 7410(k)(3); CAA Sec. 107(a) ("Each State shall have the primary responsibility for assuring air quality within the entire geographic area comprising such State by submitting an implementation plan for such State which will specify the manner in which national primary and secondary ambient air quality standards will be achieved and maintained within each air quality control region in such State." Simply put, EPA lacks discretion to decide that it would prefer a uniform national approach for Good Neighbor provisions. *Train v. Natural Resources Def. Council*, 421 U.S. 60, 79 (1975) ("The Act gives the Agency no authority to question the wisdom of a State's choices of emission limitations if they are part of a plan which satisfies the standards of § 110(a)(2), and the Agency may devise and promulgate a specific plan of its own only if a State fails to submit an implementation plan which satisfies those standards."); *Concerned Citizens of Bridesburg v. U.S. E.P.A*, 836 F.2d 777, 780–81 (3rd Cir. 1987) (holding the Clean Air Act "left the mechanics of achieving NAAQS to the states. Section 7410(a) requires each state to formulate and submit to the EPA a SIP detailing regulations and source-by-source emissions limitations that will conform the air quality within its boundaries to the NAAQS. The SIP basically embodies *a set of choices regarding such matters as transportation,*

---

[88] *See Chevron U.S.A., Inc. v. Natural Resources Defense Council, Inc.*, 467 U.S. 837 (U.S. 1984).

[89] 87 Fed. Reg. 9798, 9801, 9835 (Feb. 22,2022).

zoning and industrial development that the state makes for itself in attempting to reach the NAAQS with minimum dislocation. Because the states have primary responsibility for achieving air quality standards, the EPA has limited authority to reject a SIP."); *Commonwealth v. Environmental Protection Agency*, 108 F.3d 1397, 1410 (D.C. Cir. 1997) ("section 110 does not enable EPA to force particular control measures on the states"). Accordingly, EPA deserves no deference in any decision to prefer a nationwide FIP based on a "common core of nationwide policy judgements" over a SIP based on "a set of choices regarding such matters as transportation, zoning and industrial development that the state makes for itself."

2. EPA's decision to subject sources in upwind states to control limits stricter than the RACT level of control Congress has set for NAAQS compliance in even nonattainment areas is outside the discretion of EPA, and clearly conflicts with the structure of Title I of the Clean Air Act, the Good Neighbor provision, and the intent of Congress, and does not merit *Chevron* deference.

3. As discussed in detail throughout these comments, the many ways in which EPA analyzes and proposes to regulate non-EGUs in ways different than what has been upheld for EGUs in prior Good Neighbor rulemakings, and the various other unreasonable or arbitrary positions identified throughout these comments are not reasonable interpretations of the statute, and do not merit *Chevron* deference.

C. EPA's Consideration of Co-Benefits to Calculate Benefits of the Rule is Not Reasonable and is Arbitrary in Light of Other EPA Rulemakings

EPA justifies the costs of the Proposed Rule by accounting for not only the costs associated with ozone formation based on NOx reductions, but also based on climate impacts expected from expected co-reductions of CO2, and PM2.5 reductions based on expected co-reductions of PM2.5 and SO2.[90]

This is not reasonable or appropriate, because the statutory basis for such limits is grounded in assessing just the pollutants involved in the specific NAAQS at issue. For each NAAQS, the Good Neighbor provision provides that implementing plans may limit "any air pollutant" that contributes significantly to compliance issues with "*such national primary or secondary ambient air quality standard.*"[91] Accordingly, e.g., for the specific ozone NAAQS, the Good Neighbor

[90] E.g., Proposed Rule at 20,155; 20167; see also Regulatory Impact Analysis at 5-4 through 5-26 (incorporating PM2.5 reduction estimates when calculating health and economic benefits of the rule) & Table ES-7 through ES 10 (footnote to each admit that the "ozone benefits" in the tables actually aggregate benefits from reductions of ozone AND PM2.5) & 5-26 through 5-31 (assessing climate impacts of the rule based on CO2 co-reductions, and stating that although the EPA did not quantify benefits from CO2 reductions, EPA nevertheless took them into account as "unquantified benefits of this proposal" when evaluating the benefits of the rule; see also Data and Results for the Monetized Health Benefits Analysis as part of the Regulatory Impact Analysis.

[91] 42 U.S. Code § 7410(a)(2)(D)(i)(I).

provision allows regulation of any pollutant that contributes to compliance issues with the Ozone NAAQS (e.g. NOx), but not pollutants unrelated to Ozone compliance (CO2, PM2.5, SO2, etc.).

Moreover, EPA's approach to "baking-in" co-benefit considerations is arbitrary because it is incompatible with EPA's current promulgated final rule assessing the appropriateness of accounting for co-reductions of pollutants other than the pollutant subject to a particular regulation.[92] When assessing the appropriateness of taking into account benefits of non-HAP reductions in the context of the Clean Air Act's HAP regulations under section 112 of the Clean Air Act, EPA found that "the EPA's equal reliance on the particulate matter (PM) air quality co-benefits projected to occur as a result of the reductions in HAP was flawed as the focus of CAA section 112(n)(1)(A) is HAP emissions reductions."[93] More specifically, "Indeed, it would be highly illogical for the Agency to make a determination that regulation under CAA section 112, which is expressly designed to deal with HAP, is justified principally on the basis of the criteria pollutant impacts of these regulations. That is, if the HAP related benefits are not at least moderately commensurate with the cost of HAP controls, then no amount of co-benefits can offset this imbalance for purposes of a determination that it is appropriate to regulate under CAA section 112(n)(1)(A)."

Although CAA Sections 112(n)(1)(A) and 110(a)(2) are separate statutory schemes, the cost/benefit analysis must be treated consistently because both treatment of cost under each provision is based on the same question: whether a given regulation is "appropriate" and "necessary." [94] Accordingly, because the Ozone NAAQS is focused on ozone reductions, any Good Neighbor implementation plan under the Ozone NAAQS should also only be considered "appropriate" if the ozone benefits are commensurate to the costs, without relying on co-benefits from PM2.5 reductions and climate considerations, since both are outside the scope of the Ozone NAAQS.

Reg. 2670; see also "Final Rule: National Emission Standards for Hazardous Air Pollutants: Coal- and Oil-Fired Electric Utility Steam Generating Units—Reconsideration of Supplemental Finding and Residual Risk and Technology Review," 85 Fed. Reg. 31,286, 31,299 (May 22, 2020) ("finalizing the determination outlined in the 2019 Proposal").

[93] 84 Fed. Reg. at 2676.

[94] *Compare* U.S. Code § 7412(n)(1)(A) ("The Administrator shall regulate electric utility steam generating units under this section, if the Administrator finds such regulation is *appropriate and necessary*"), *with* 42 U.S. Code § 7410(a)(2)(A) (providing that implementation plans for each individual criteria pollutant under Section 110 "shall" "include enforceable emission limitations and other control measures, means, or techniques (including economic incentives such as fees, marketable permits, and auctions of emissions rights), as well as schedules and timetables for compliance, as may be *necessary or appropriate* to meet the applicable requirements of this chapter").

D. EPA's Disregard for Demonstrations of Infeasibility Miscomprehends the Precedent EPA Relies On.

EPA makes the assertion that it is authorized to ignore "claims about infeasibility of controls" raised by any facility, citing solely to the D.C. Circuit's opinion in *Wisconsin v. EPA*.[95] But EPA mischaracterizes the D.C. Circuit decision. In *Wisconsin*, the court simply required that the deadline for upwind state compliance with Good Neighbor provision align with downwind states deadlines for compliance with a given NAAQS. In doing so, it is true that the court rejected an EPA argument that it was infeasible to require compliance with the Good Neighbor provision in a timely manner, but the discussion of "feasibility" was not about technical feasibility of whether controls would be capable of being retrofitted and or concerning whether controls could actually feasibly reduce the emissions to the extent needed. Rather, the "feasibility" issues the court and EPA discussed in that context instead concerned whether EPA had enough time and information to draft and implement required reductions in a timely manner.[96]

It is also readily apparent that the technical feasibility questions raised by the Proposed Rule's unit level emission limits are categorically different than the "feasibility" concerns discussed in *Wisconsin*, because the rule at issue in *Wisconsin* involved only statewide emission budgets and did not involve any command-and-control limits like those now proposed. Furthermore, it would be one thing if EPA simply had a statewide emission cap requiring absolute reductions in NOx, because then a facility could meet the limit by operating less if it is absolutely necessary for emissions to decrease in order to meet downwind attainment, but EPA's proposal goes beyond that, with the efficiency based lb/mmBtu limits that may make it literally impossible to comply if the proposed controls cannot feasibly reduce emissions to the extent EPA assumes due to the differences in the steelmaking process than coal fired powerplants, whereas overall emission budget reductions would still accomplish any mandate faced by EPA due to *Wisconsin* while giving facilities the flexibility to meet them in the most efficient and technically feasible manner, or in the worst case to operate less.

VIII. EPA's Decision to Deny Non-EGUs Compliance Flexibility is Arbitrary and Capricious

A. It is Arbitrary to Deny Non-EGUs Compliance Flexibility Granted to EGUs

A key component of the currently established CSAPR rule is that it provides for trading of NOx emission credits. The Proposed Rule itself recognizes that "the current CSAPR trading program structure . . . has important positive attributes, particularly with respect to the exceptional degree of compliance flexibility it can provide. . . .".[97] As described in the Proposed Rule, "[t]he trading program's option to buy additional allowances provides flexibility in the program for

---

[95] Proposed Rule at 20,104 & n.242 (citing Wisconsin v. Envtl. Prot. Agency, 938 F.3d 303 (D.C. Cir. 2019)).

[96] See 81 Fed. Reg 74,504, 74,552 (Oct. 26, 2016) ("a remedy simply is not feasible *in the existing timeframe*. . . . the agency does not have sufficient information at this time to promulgate such a rule.").

[97] 87 Fed. Reg. at 20,107.

outlier sources that may need more time than what is representative of the fleet average to implement these mitigation strategies while providing an economic incentive to outperform rate and timing assumptions for those sources that can do so. In effect, this trading program implementation operationalizes the mitigation measures as state-wide assumptions for the EGU fleet rather than unit-specific assumptions." [98]

For non-EGUs, the Proposed Rule arbitrarily includes no similar flexibility. The Proposed Rule in fact includes no flexibility at all. There is no allowance for variances from EPA's "command-and-control" emission limits for facilities that cannot retrofit EPA's required pollution control equipment or achieve the extreme reductions the Proposed Rule prescribes even after installing EPA's selected technology. There is no process for submitting an alternative control strategy to EPA or for non-EGUs or the states in which they are located, to offset the emission reductions mandated by the Proposed Rule with other, more cost-effective emission reductions. There is not even an opportunity to extend deadlines if it is found that the required pollution control and monitoring equipment required by the Proposed Rule cannot be purchased and installed on the schedule mandated by EPA.

While the Proposed Rule should not be finalized in any form, if EPA does proceed with finalizing a FIP for interstate transport of ozone, it must afford compliance flexibility for all subject sources, not just EGUs. EPA should consider extending emission trading to non-EGUs so that a disproportionate burden is not placed on non-EGUs to achieve emission reductions not required of other sources. EPA should also include a process for regulated sources or affected states to petition for variances from the required emission limits and compliance schedules upon a demonstration of infeasibility or impracticality.

B. EPA's Decision to Exclude All Non-EGUs from the Emissions Trading System Arbitrarily Reverses Prior Agency Determinations Without Justification.

EPA's decision to exclude all non-EGU's from the emissions trading program is a major regulatory about-face by the agency which it neither recognizes nor confronts, impermissibly attempting to "depart from a prior policy *sub silentio*." *See FCC v. Fox TV Stations, Inc.*, 556 U.S. 502, 515 (2009). EPA has consistently endorsed an emissions trading program over unit-specific limitations, and the Proposal fails to adequately justify the decision to categorically exclude non-EGUs from the trading program.

In April 2021, EPA explained that the trading program "not only encourages units to achieve the rates assumed in the budget-setting process, but to perform at even better rates where better performance can be achieved at a cost lower than the allowance price. By contrast, an implementation mechanism that provides a unit-specific emission rate would not incentivize the unit to perform better than its rate requirement."[99] EPA further stated that "unit-specific short-term emission rates pose significant implementation and rulemaking challenges," and if EPA were "to

---

[98] *Id.* at 20,100.

[99] EPA Final Rule – Revised Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS, pg. 65 (published April 30, 2021).

choose to implement a unit-specific emissions rate regime for implementation, the compliance flexibility afforded by emissions trading would not be available and it would not be possible to rely on fleet average information to the same extent . . . ."[100]

Nevertheless, EPA now proposes to exclude non-EGUs from the trading program. In a mere two paragraphs, EPA seeks to justify this exclusion by asserting that if it "were to include non-EGUs in the trading program, [it] would require monitoring and reporting of hourly mass emissions . . . as [it has] for all trading programs." The Proposal therefore concludes that "applying unit-level emissions limitations . . . rather than constructing an emissions trading regime is more administratively feasible and more easily implementable at the source level . . . ." This proposed exclusion is arbitrary and capricious for a number of reasons.

First, the Proposed Rule already requires the installation of monitoring equipment for non-EGUs. The Proposal explicitly states:

> "The EPA is proposing to require each owner or operator of an affected facility that is subject to the NOx emissions limit for Iron and Steel Mills and Ferroalloy Manufacturing emissions units contained in this section to install, calibrate, maintain, and operate a CEMS for the measurement of NOx emissions discharged into the atmosphere from the affected facility. The EPA is proposing that each emissions unit will be required to conduct an initial performance test and to operate CEMS to assure compliance."[101]

Thus, EPA's rationale for excluding non-EGUs from the trading program—that including them "would require monitoring and reporting," including "CEMS (or an approved alternative method)"[102]—is internally inconsistent, arbitrary, and capricious. EPA is proposing to require iron and steel industry units subject to the Proposed Rule to install CEMS or monitoring equipment anyway.

Moreover, when EPA initiated the trading program, it provided EGUs with no less than two-and-a-half years to install monitoring equipment.[103] But EPA now appears to believe that three-and-a-half years (until the compliance deadline of 2026) is an inadequate amount of time, warranting the exclusion of non-EGUs from the trading program. EPA does not provide any reason for this shift other than to note general uncertainty as to how long it may take non-EGUs to install monitoring equipment. But "where an agency is uncertain about the effects of agency action, it may not rely on 'substantial uncertainty' as a justification for its actions."[104] "Instead, EPA must

[102] *Id.* At 20,141.

[103] Clean Air Interstate Rule, 70 Fed. Reg. 25,161 (May 12, 2005).

[104] *Scholl v. Mnuchin*, 489 F. Supp. 3d 1008, 1036 (N.D. Cal. 2020), quoting *Greater Yellowstone Coal., Inc. v. Servheen*, 665 F.3d 1015, 1028 (9th Cir. 2011).

'rationally explain why the uncertainty' supports the chosen approach."[105] EPA's failure to justify its "depart[ure] from a prior policy" renders the decision to exclude non-EGUs from the trading program "arbitrary and capricious."[106]

Additionally, EPA's assertion that it has "require[d] monitoring . . . for all trading programs," lacks one crucial clarification. When EPA initiated the trading program, the provision requiring use of CEMS still provided a process for a "unit that does not meet the applicable compliance date" for installing monitoring equipment to "determine, record, and report substitute data"[107] in lieu of CEMS data. If EPA determines that CEMS are both necessary and appropriate (including but not limited to cost justified), EPA should likewise provide a process for providing "substitute data" in the hypothetical event that certain units are unable to install monitoring equipment by 2026 or confront and justify it decision to deny non-EGUs this ability provided to EGUs.

Finally, the assertion that unit level controls are superior for non-EGUs because they are (in some unexplained way) "more administratively feasible and more easily implementable at the source level" is fatally inconsistent not just with EPA's prior findings, <u>but with the Proposed Rule itself</u>, which elsewhere expressly finds that an emission trading program is superior to direct controls for EGUs because "trading program's option to buy additional allowances provides flexibility in the program for outlier sources that may need more time than what is representative of the fleet average to implement these mitigation strategies while providing an economic incentive to outperform rate and timing assumptions for those sources that can do so. In effect this trading program implementation operationalizes the mitigation measures as state-wide assumptions for the EGU fleet rather than unit-specific assumptions."[108]

IX. Timing of Compliance for States Linked Only to Maintenance Receptors

EPA currently subjects states linked only with maintenance receptors[109] to the same 2026 deadline EPA sets as applicable to states linked to nonattainment receptors. But as explained below, this is based on an erroneous legal assumption that all compliance must be in place by 2026, when in fact EPA retains discretion with regard to states that are not linked to any nonattainment receptors. Furthermore, the 2026 deadline should not bind states only linked to maintenance areas, or in any case, requirements should be suspended as long as the linked receptors are in attainment, with obligations triggered only if the maintenance receptors slip into nonattainment, as explained below.

---

[105] *Id.*

[106] *FCC v. Fox TV Stations, Inc.*, 556 U.S. 502, 515-16, 129 S. Ct. 1800, 1811 (2009).

[107] Clean Air Interstate Rule, 70 Fed. Reg. 25,161, 25,355 (May 12, 2005).

[108] Proposed Rule, pg. 20,100.

[109] I.e., Arkansas, Minnesota, Mississippi, Oklahoma, Wisconsin and Wyoming. See Air Quality Modeling TSD at D-1 to D-11.

The entire basis for the EPA selecting the 2026 ozone season compliance deadline for non-EGUs in the Proposed Rule is *Wisconsin v. EPA*'s requirement that EPA to tie upwind-State's Good Neighbor compliance to downwind-State's nonattainment deadlines or the earliest possible time thereafter, paired with EPA's finding that the 2026 ozone season is the first possible season during which the non-EGU limits proposed in the Proposed Rule can feasibly go into effect (which is aligned with the August 3, 2027, attainment date for areas classified as Serious nonattainment under the 2015 ozone NAAQS).[110]

But *Wisconsin* merely required "upwind States to eliminate their significant contributions in accordance with the deadline by which downwind States must come into compliance with the NAAQS."[111] And notably, this only requires linkage of deadlines when it is required for a downwind state to come into attainment, meaning that it does not govern maintenance receptors trending toward full attainment, such as the Brazoria County, TX receptor which EPA models to be in attainment before 2026 (i.e., where the receptor is in attainment, albeit maintenance, and thus the downwind state is in compliance with the NAAQS at that receptor such that no upwind reductions are needed by any specific time).

Accordingly, EPA's application of the 2026 deadline to states linked only to improving maintenance receptors (e.g., Arkansas, Minnesota, Mississippi, Oklahoma, Wisconsin, Wyoming) is legally erroneous, since EPA's current rationale is that such a deadline is mandated by *Wisconsin v. EPA*'s, when in fact it is not, and thus EPA must provide a discretionary rationale if it wishes to subject such states to the same deadline as states linked to nonattainment receptors.[112]

Additionally, it would be consistent with *Wisconsin v. EPA* to suspend applicability of the Proposed Rule's limits to Arkansas and Mississippi so long as the Brazoria County, TX receptor is in attainment by 2026, and EPA should do so given the specific characteristics and trend of the Brazoria receptor. As explained below, to truly link upwind state compliance deadlines to downwind compliance deadlines, EPA should suspend Good Neighbor compliance deadlines for states solely linked to a maintenance receptor unless and until such a maintenance receptor slips into nonattainment. After all, once the Brazoria receptor is no longer in nonattainment, Texas' obligations "to submit attainment demonstrations and associated RACM, RFP plans, contingency measures for failure to attain or make reasonable progress, and other planning SIPs related to attainment of the ozone NAAQS for which the determination has been made, *shall be suspended* until such time as: The area is redesignated to attainment for that NAAQS, at which time the requirements no longer apply; or the EPA determines that the area has violated that NAAQS, at which time the area is again required to submit such plans." [113] Thus, for example, it would be

[110] Proposed Rule at 20,099-100.

[111] *Wisconsin v. EPA*, 938 F.3d 303, 313 (D.C. Cir. 2019).

[112] See *Prill v. N.L.R.B*, 755 F.2d 941, 942 (D.C. Cir. 1985) (concluding that where an agency erroneously assumed that a determination was mandated and outside of the agency's discretion, the determination "stands on a faulty legal premise and without adequate rationale.").

[113] 40 CFR § 51.1318.

incongruous to require upwind emission reductions in 2026 based solely on contributions to the Brazoria County, TX if Texas' obligations with respect to the same receptor are suspended based on this receptor measuring in attainment by that time. This is especially justified for Arkansas given the upcoming closures of NOx sources like the White Bluff plant by 2028, leading to even further NOx reductions from Arkansas than taken into account by EPA.

Specifically for the Brazoria County, Texas receptor it is currently designated as marginal nonattainment, but EPA has proposed to redesignate it pursuant to CAA section 181(b)(2)(A)(i) and 40 CFR 51.1303 based on failure to attain by the deadline for marginal nonattainment, thus requiring the receptor to be attain the 2015 Ozone NAAQS by the next deadline of "no later than 6 years after the initial designation as nonattainment, which in this case would be no later than August 3, 2024"[114] EPA's modeling as part of the Proposed Rule models the Brazoria receptor reaching attainment (albeit maintenance status) by 2023 or before, expecting the receptor no longer be in nonattainment, such that Texas' obligations would be expected to be suspended with respect to that receptor at that time in 2024, and if Texas meets that attainment deadline as anticipated by EPA, the receptor could even be officially redesignated as no longer nonattainment before 2026 when the Proposed Rule's non-EGU limits are proposed to take effect. Thus, given the particular circumstances of the Brazoria receptor, including its specific deadline for attainment and EPA's modeling in the Proposed Rule, EPA should suspend applicability of the Proposed Rule's non-EGU limits on states linked solely to the Brazoria receptor so long as the Brazoria receptor is in attainment by the appropriate deadline. If, however, the receptor slips back into nonattainment after that time, then any necessary Good Neighbor provisions in states linked to that maintenance receptor would be triggered, with the provisions EPA currently proposes to be effective 2023 to instead become effective in the event the Brazoria receptor slips into nonattainment, with the provisions currently proposed for 2026 ozone season becoming effective three years from the date the Brazoria receptor actually slips to nonattainment.

X. Unreasonable Limitations on Public Comment

A. EPA Should Allow More Time for Public Comment

EPA is proposing to impose unprecedented unit-level emissions limitations on a wide array of industries and jurisdictions. There was virtually no effort to gather industry input prior to regulation, and as discussed above, little more effort has been made to review and incorporate data and comments from the states.

The Proposed Rule itself covers 181 pages, and the record still has numerous omissions. Yet EPA has provided only 11 weeks for public comment. While U. S. Steel appreciates the extension that extended the initial deadline by two weeks, this is still not enough time for proper public input on such an extensive attempt at regulation, and as noted throughout these comments, does not provide the time to perform the various analyses EPA failed to perform as part of the

[114] "Determinations of Attainment by the Attainment Date, Extensions of the Attainment Date, and Reclassification of Areas Classified as Marginal for the 2015 Ozone National Ambient Air Quality Standards" 87 Fed. Reg. 21,842, 21,850 (April 13, 2022).

Proposed Rule, including but not limited to facility- and unit-specific contribution modeling and facility- and unit-specific feasibility assessments, both of which must be prerequisites to any exercise of EPA authority under the Good Neighbor provision. To ensure an adequate process for public input, EPA must allow time for interested parties to analyze EPA's data and prepare supplemental information and comments.

B. EPA's Denial of U.S. Steel's Request for Additional Time for Comments is Unjustified.

U. S. Steel separately requested an additional extension (EPA-HQ-OAR-2021-0668-0244), which EPA denied on June 17, 2022. EPA's denial essentially relies on two grounds to deny the extension request. First, EPA relies on the claim that it must not further extend comments because EPA has an obligation to move "as expeditiously as practicable." But as noted in the State of Arkansas' comments on EPA's proposed denial of Arkansas' proposed Good Neighbor SIP provisions for the 2015 Ozone NAAQS, EPA delayed evaluation of underlying state SIP submissions and modeling for more than a year.[115] It is unreasonable for EPA to delay any evaluation of Good Neighbor provision requirements and then use that very delay as a reason to prevent the public from having adequate time to evaluate and comment on EPA's proposed approach. EPA's other rationale is that EPA provided some of the materials underlying the Proposed Rule prior to the formal publication of the Proposed Rule in the Federal Register. But this does not address the facts that (1) EPA's choice to pursue unit specific reductions entails requires detailed facility- and unit-specific modeling and engineering studies to evaluate contribution to downwind receptors and feasibility, availability, and cost of proposed controls, which can take months to complete in the detail necessary to fully evaluate the Proposed Rule's unprecedented limits that have never been achieved by any known source to date; and (2) that information needed to evaluate the Proposed Rule was not provided until after the Proposed Rule was published in the Federal Register. Simply re-running the CAMx modeling can take months and EPA took several weeks to provide the modeling data referenced in the Proposed Rule upon request, not providing the modeling files needed to adequately comment on EPA's modeling until over a month after publication of the Proposed Rule.

C. EPA Must Reissue the Rule For Additional Comment if Substantive Changes in Approach Are Made in the Final Rule.

The rulemaking procedures at section 307(d) of the CAA specifically require that a proposed rulemaking must "include a summary of—(A) the factual data on which the proposed rule is based; (B) the methodology used in obtaining the data and in analyzing the data; and (C) the major legal interpretations and policy considerations underlying the proposed rule" and "All data, information, and documents referred to in this paragraph on which the proposed rule relies shall be included in the docket on the date of publication of the proposed rule."[116] Furthermore,

---

[115] See Comment submitted by Arkansas Department of Energy and Environment, Division of Environmental Quality, on EPA-R06-OAR-2021-0801-0001, at 3-4 (April 22, 2022).

[116] 42 U.S.C. § 7607(d)(3).

any final "promulgated rule may not be based (in part or whole) on any information or data which has not been placed in the docket as of the date of such promulgation."[117] Relatedly, EPA has "an initial burden of promulgating and explaining a non-arbitrary, non-capricious rule" including an obligation to "explain how the standard proposed is achievable under the range of relevant conditions which may affect the emissions to be regulated."[118]

Accordingly, it would be unlawful for EPA to make any revisions to the Proposed Rule that are not supported by the data in the docket, including but not limited to subjecting additional units to the Proposed Rule where the feasibility, cost effectiveness, and significance to downwind receptors is not included in the docket supporting the Proposed Rule, absent a new proposed rule providing the opportunity for public comment on the basis for any such newly proposed changes. Furthermore, it would be arbitrary for EPA to reverse any of the determinations it has made in this Proposed Rule, such as by including emission units or sources not currently proposed to be included in the Proposed Rule or the draft regulation accompanying the Proposed Rule or imposing a trading system or other controls rather than the current proposed controls, without first re-issuing such changes in the form of a new proposed rule for additional public comment.

XI. EPA Should Reconsider the National Applicability of the Proposed Rule.

EPA proposes to find that this proposed action, "if finalized, would be 'nationally applicable' within the meaning of CAA section 307(b)(1)" or, in the alternative, that "this action is based on a determination of 'nationwide scope or effect" within the meaning of CAA section 307(b)(1)." This is based on EPA's finding that the "proposed action applies a uniform, nationwide analytical method and interpretation of CAA section 110(a)(2)(D)(i)(I) across these states, and the proposed rule is based on a common core of legal, technical, and policy determinations (as explained in further detail in the following paragraph). For these reasons, this proposed action is nationally applicable."[119].

EPA's proposal is not well founded. The Proposed Rule notes that if finalized, it will "implement the good neighbor provision in 26 states, spanning 8 EPA regions and 10 federal judicial circuits."[120] This is only because EPA has aggregated several rulemakings into the Proposed Rule. The FIP applies on a state-by-state basis. That EPA failed to make the state-specific assessments required for a proper review of each State's SIP and replacement with a FIP

[117] 42 U.S.C. § 7607(d)(6)(C).

[118] *National Lime Ass'n v. E. P. A.*, 627 F.2d 416, 433 (D.C. Cir. 1980) (in the context of a new source performance standard rulemaking procedure subject to 42 U.S.C. § 7607(d), holding that "an initial burden of promulgating and explaining a non-arbitrary, non-capricious rule rests with the Agency and we think that by failing to explain how the standard proposed is achievable under the range of relevant conditions which may affect the emissions to be regulated, the Agency has not satisfied this initial burden."); *see also Nat. Res. Def. Council v. EPA*, 755 F.3d 1010, 1023 (D.C. Cir. 2014) ("EPA retains a duty to examine key assumptions as part of its affirmative burden of promulgating and explaining a nonarbitrary, non-capricious rule and therefore EPA must justify that assumption even if no one objects to it during the comment period.") (citation, internal question marks, and ellipses omitted).

[119] Proposed Rule at 20,168

[120] Proposed Rule at 20,168.

is not a justification for stripping the applicable regional courts of jurisdiction over what are inherently state-specific issues.

EPA's alternative approach, to find that the "proposed action is based on multiple determinations of nationwide scope or effect for purposes of CAA section 307(b)(1)" is similarly inadequate. Using a "common core of statutory and case law analysis, factual findings, and policy determinations concerning the transport of ozone-precursor pollutants from the different states subject to it, as well as the impacts of those pollutants and the impacts of options to address those pollutants in yet other states"[121] to find that a state-specific rule has national applicability is to find that the exception swallows the rule. Most state-specific rules EPA promulgates are based on a "common core of statutory and case law analysis, factual findings, and policy determinations." This is part of what prevents EPA from acting arbitrarily and capriciously. If this were sufficient to make a state-specific rule nationally applicable, then almost all EPA rulemaking would be forced into the D.C. Circuit for judicial review.

XII. Miscellaneous Comments, and Responses to EPA Requests for Comment

A. Applicability Provisions Require Clarification:

There are multiple aspects of the Proposed Rule's applicability which should be clarified before proceeding to final rule.

1. First, it appears that the Proposed Rule will only cover emission units which are individually under 100 tons per year in the case of facilities with a Basic Oxygen Process Furnace, for which the Proposed Rule would aggregate emissions from the "BOF Shop" for purposes of determining the Proposed Rule's applicability to units in the "BOF Shop."[122] EPA should further clarify what is unique about BOF operations that require them to be aggregated for applicability purposes rather than each emission unit being subject to a 100 tpy applicability threshold like other furnaces. Furthermore, because the Proposed Rule does not contain any NOx emission standard applicable to a BOF Shop as a whole, and because the activities listed as constituting a BOF appear to include activities that are not one of the furnace types regulated under the Proposed Rule (e.g. hot metal transfer and desulfurization), and because the processes noted as constituting a BOF Shop do not appear to be the type of activities that each have separate stacks, the final rule should clarify how a BOF Shop will demonstrate compliance with the emissions in the rule (e.g., if all emissions in a BOF Shop are vented through the same venting system, then a BOF Shop should be able to aggregate the individual limits of any units within the BOF Shop in making its compliance demonstration, or should be subject to a separate overall limit for a BOF Shop).
2. The definition of a reheat furnace as currently drafted is overly vague and should be amended to match the reheat furnaces (and related definitions) on which EPA's review was

[121] Proposed Rule at 20,168

[122] Proposed Rule at 20,181.

based. The current definition of a reheat furnace in the Proposed Rule is "a furnace used to heat steel product to temperatures at which it will be suitable for deformation and further processing."[123] This definition does not define what counts as "steel product" (e.g., does it include only products that have already been manufactured into some form prior to being introduced to a reheat furnace, or does it include steel that has never left the original production process, such as hot steel coming directly from a connected casting process which has not yet been formed into a definitive product). When setting a limit for reheat furnaces in the Proposed Rule, EPA expressly relied on the Ohio RACT limit for reheat furnaces.[124] Ohio's applicable definition (i.e. defining the universe of units the RACT limit EPA relied on applied to) provides that " 'Reheat furnace' means a furnace in which metal ingots, billets, slabs, beams, blooms and other similar products are heated to bring them to the temperature required needed for hot-working."[125] This definition is also consistent with the various permits that EPA looked at when setting a limit for a reheat furnace.[126] EPA should likewise clarify its definition of reheat furnace to match the definition used by Ohio or otherwise make the definition more clearly limited to the types of units and limits EPA considered in setting the emission limits for reheat furnaces in the Proposed Rule. This clarification should more clearly differentiate a reheat furnace, which handles pre-made intermediate products, from something like a tunnel furnace that merely maintains and equalizes the temperature of raw already-hot-slabs while in transit from a caster to some other operation like a rolling mill. Any other approach that broadens applicability of the definition of reheat furnace beyond the type of sources EPA reviewed in setting its proposed emission limit would be arbitrary, since it would be unreasonable and arbitrary to regulate a unit without any reasoned basis for subjecting it to that emission limit.

3. EPA should also resolve the current discrepancy concerning the basis for the 40% reduction EPA is requiring at reheat furnaces. The Proposed Rule states that a 40% reduction is assumed based on installation of SCR,[127] whereas the underlying Non-EGU Sectors TSD states that the 40% reduction is instead based on low-NOx burners, not including SCR.[128] Either way, EPA must also provide additional rationale for the reductions, because assuming reductions based solely on the basis of low NOx burners may be inconsistent with the fact that the permit limits EPA reviewed in setting this limit, specifically Sterling Steel, already had low-NOx burners installed, and thus it may not be reasonable to assume

[123] Proposed Rule at 20,181.

[124] Non-EGU Sectors TSD at 42.

[125] OAC 3745-110-01 (35).

[126] See Non-EGU Sectors TSD at 42, pointing to permit limits at Sterling Steel, Charter Steel, and United States Steel Lorain Tubular Operations, each of which specifies a premade product that the reheat furnace accepts as an input, i.e. a "Billet" reheat furnace at Sterling Steel, a "Bar Mill" reheat furnace at Charter Steel. Likewise, the US Steel Lorain Tubular facility reheat furnaces handle products made elsewhere as inputs and are not handling raw product.

[127] Proposed Rule at 20,145.

[128] Non-EGU Sectors TSD at 43.

additional emission reduction since those controls are already in place. By contrast, if the reductions are based on assumption of SCR feasibility, then EPA must detail why EPA believes SCR to be feasible and cost effective for such units, which it has not done specifically to reheat furnaces.

4. The Proposed Rule should clarify what if any limit is applicable to galvanizing furnaces. The Non-EGU Sectors TSD mentions galvanizing furnaces several times, often in the same context as annealing and reheat furnaces, such as when EPA identifies a Wisconsin NOx RACT limit of 0.08 lb/mmBtu which applied to reheat, annealing and galvanizing furnaces.[129] Furthermore, the technical support document also distinguishes between reheat, annealing, and galvanizing furnaces as separate types of units.[130] However, the final rule includes different limits for annealing furnaces (0.06 lb/mmBtu) and reheat furnaces (0.05 lb/mmBtu), and does not include a separate galvanizing furnace limit. Accordingly, EPA should clarify whether galvanizing furnaces are intended to be included under the limits applicable to reheat furnaces, annealing furnaces, or neither, including appropriately detailed rationale.

B. The Proposed Rule's Emission Unit Specific Limits and Monitoring Requirements Will Not be Practicably Enforceable for Units that Lack Unit Specific Stacks.

The Proposed Rule appears to assume that each different unit is stacked such that its emissions could be disaggregated from other units, but that is not the case. Some units share a joint stack, some have multiple stacks, and some are so minor as to not be stacked. Accordingly, the Proposed Rule, if finalized, must allow for flexibility in demonstrating compliance with associated emission limits.

For example, the Proposed Rule establishes separate limits for EAFs, LMFs, and ladle/tundish preheaters. But LMFs and ladle/tundish preheaters are relatively small sources of emissions at the U. S. Steel's BRS facility (and future EV facility) are not vented through a separate stack. Rather, the EAF and LMF and other small units in the melt shop such as ladle/tundish preheaters are typically hooded and exhausted through the same canopy system to the baghouse where the joint emissions then vent to the baghouse and the primary exhaust stack. Accordingly, it is not possible to separately monitor preheater, LMF, and EAF emissions with CEMS, or to verify separate emission limits, since any compliance demonstration, whether by CEMS or stack testing, will necessarily be based on a joint measurement of preheater, LMF, and EAF emissions. This is reflected in BRS's and EV's current air permits, which provides a joint lb/hr emission limit for an LMF and EAF combined. Accordingly, to the extent the final rule still imposes command-

[129] Non-EGU Sectors TSD at 42.

[130] Non-EGU Sectors TSD at 26 ("Annealing involves a supplemental heating process to change the hardness properties of the final steel produced and ensure homogeneity. The galvanizing process coats iron or steal in a coating of molten zinc to protect and seal, limiting rust and corrosion. Reheat furnaces are used in hot rolling mills to heat steel slabs for rolling into sheets").

and-control limits for individual emission units, the final rule should take this reality into account by either creating a joint limit for an EAF, LMF and preheaters combined, or by allowing EAF, LMF, and preheater emissions to be aggregated for purposes of any compliance demonstration of their combined limits. Furthermore, EAFs are the only units that are over 100 tpy at U. S. Steel BRS and EV facilities subject to the Proposed Rule, and thus the Proposed Rule would not apply to LMF and preheaters, at least at these facilities. Thus, EPA should clarify how compliance with the proposed emission limits for EAFs will be demonstrated, given the fact that any CEMS installed on an EAF stack will reflect emissions from other units which may not even be subject to limits under the Proposed Rule.

By contrast, other units like the tunnel furnaces at the BRS facility have as many as five stacks per furnace due to the physical length of the tunnel transportation process. It cannot be assumed that these could be redesigned to a single stack, because due to design and overlapping influence within the tunnel furnaces the atmospheric conditions as it relates to the burners can potentially have different requirements for one stack versus another and could adversely affect the facility and steel quality. Accordingly, when performing cost estimates to determine the appropriateness of any efficiency limits EPA proposes for such furnaces, EPA must take into account the cost of multiple SCR and CEMS rather than assuming that a single CEMS and SCR could be installed on such units. For clarity, these units have less than 100 tpy NOx potential emissions at the U. S. Steel BRS facility, and as noted in the previous comment, it is unclear whether a tunnel furnace designed solely to maintain temperatures of hot-steel would in any-case be covered by the Proposed Rule.

Finally, annealing units can vary greatly in size and amenability to controls. For example, the batch annealing furnaces at the U. S. Steel BRS facility (and the EV facility under construction) entail such small amounts of emissions that they are not stacked and thus cannot be subjected to unit specific SCR, much less CEMS.

C. Efficiency Based Form of Proposed Emission Limits is Unreasonable

EPA provides no persuasive justification for imposing efficiency limits (i.e., lb/mmBtu limits) instead of emission limitations tied to the actual reductions needed to eliminate an upwind state's significant contribution. EPA's statutory authority under the Good Neighbor provision is solely intended to be used to reduce an absolute "amount" of emissions for the tailored purpose of achieving downwind NAAQS attainment[131], and is not an appropriate means to force industrywide standards of performance; if the efficiency standards preferred by EPA can be justified, then EPA can pursue that objective through NESHAP and NSPS standards. Furthermore, EPA's modeling relied on estimates of tons of reductions expected throughout each state, and EPA's compliance method is a CEMS, both of which are directly linked to absolute emissions, rather than emission efficiency. Finally, mandating efficiency-based limits arbitrarily and unreasonably eliminates the option for affected facilities to achieve any required emission reductions during ozone season through reduced operations, which could be just as effective at achieving any reductions needed

[131] 42 U.S. Code § 7410(a)(2)(D)(i)(I).

to achieve any obligations under the Good Neighbor provision. A lb/mmBtu limit puts affected facilities, especially those with higher-than-average retrofit costs in a challenging situation, forced to choose between infeasible costs, or being shut down altogether. By contrast, limits like those that EPA has proposed in the past which only require statewide reductions by the amount emissions modeled to eliminate an upwind state's significant contribution would at least provide owners of such facilities with a tenable option of reducing emissions through reduced utilization during ozone season short of complete shutdown.

D. Unit Specific Nature of Limits Fails to Consider Alternate Emission Reductions

The unit specific nature of the proposed efficiency limits eliminates facility flexibility in reducing overall NOx emissions in more technically feasible and cost-effective ways. Although the Proposed Rule continues to grant EGUs some limited flexibility in figuring out how best to reduce emission to meet limits (which in some cases includes complete facility shutdown), the Proposed Rule robs non-EGUs of the same flexibility. Different facilities face different design and operational limitations, and the operators of each facility are in the best position to assess how to maximize emission reductions while minimizing process impacts. For example, in cases where installation of controls on an applicable furnace is not feasible, facilities should instead have the flexibility to achieve the same level of emission reductions through other means, for example a facility may still have the option of low NOx optimizations on units that would otherwise not be subject to the Proposed Rule, such as furnaces or boilers that are not of sufficient size to be included under the Proposed Rule.

E. Climate Change is Not Carte Blanche to Tighten Regulations and NAAQS Without Notice and Comment

EPA makes a generalized appeal to climate change as an excuse to find that Arkansas, Mississippi, and Wyoming are not overcontrolled by the Proposed Rule, despite EPA's models suggesting they are overcontrolled, because "future ozone concentrations and the formation of ground level ozone, may be impacted by climate change in future years," and relying on uncertainty rather than even attempting to model any climate change effect.[132] But "where an agency is uncertain about the effects of agency action, it may not rely on 'substantial uncertainty' as a justification for its actions. Instead, it must 'rationally explain why the uncertainty' supports the chosen approach."[133] And handwaving about uncertainties associated with climate change is not an excuse for increasing control stringency by overcontrolling emissions under the Good Neighbor provisions of the Clean Air Act, which are focused solely on NAAQS, absent proper regulatory and statutory authorization.[134]

[132] E.g., Proposed Rule at 20,099.

[133] *Scholl*, 489 F. Supp. 3d at 1036.

[134] To the extent EPA is attempting to use climate change considerations to make the 2015 Ozone NAAQS more stringent without going through the rulemaking process to revise the 2015 Ozone NAAQS. Any attempt by USEPA to do so in the context of the Proposed Rule would not be consistent with EPA legal obligations under the CAA.

F. It Would be Arbitrary for EPA to Not Include Waste Incinerators in the Final Rule If Other Non-EGUs Are Included

The current draft of the Proposed Rule does not propose to regulate (1) EGUs less than or equal to 25 MW, (2) solid waste incineration units, and (3) cogeneration units, each of which, just like the Iron and Steel industry and all other non-EGUs, have traditionally been excluded from EPA's interstate air transport programs. [135] Accordingly, any potential emission reductions from such facilities were not included when EPA estimated state-by-state potential NOx reductions under the Proposed Rule. [136] But EPA also requested comment on whether these must be included, and specifically noted that EPA is "considering whether to include emissions limitations for solid waste incineration units" in the Final Rule.[137]

It would be arbitrary for EPA to require reductions at the proposed non-EGUs, but not include waste incinerators. By EPA's own analysis, such waste incinerators emissions can be an order of magnitude larger than the applicability limits EPA is using to subject other industries like steel mills to command-and-control limits.[138] The questions EPA requests comment on when EPA considers whether to include waste incinerators in the final rule are generally valid questions (e.g., feasibility and cost effectiveness of controls). But EPA's resulting position is incorrect.

For example, there are potentially many such units in Arkansas, including units with permitted NOx emissions at least as high as steel industry units, and far closer to the Brazoria TX receptor than U. S. Steel's BRS and EV facilities.[139] In the Proposed Rule, EPA seeks to impose emission limits on non-EGUs such as EAFs without providing any analysis of technical feasibility

[137] Proposed Rule at 20,084.

[138] Non-EGU Sectors TSD at Table 8.

[139] The following facilities, are not an exclusive list, but includes various incineration facilities under NAICS codes 562213(Solid Waste Combustors and Incinerators) or 562211 (Hazardous Waste Treatment and Disposal): Elemental Environmental Solutions LLC, Arkadelphia, 1016-AOP-R15, (245.7tpy NOx), https://www.adeq.state.ar.us/downloads/WebDatabases/PermitsOnline/Air/1016-AOP-R15.pdf; Clean Harbors LLC, El Dorado, 1009-AOP-R24 (535.7tpy NOx), https://www.adeq.state.ar.us/downloads/WebDatabases/PermitsOnline/Air/1009-AOP-R24.pdf. Furthermore, the following facilities are registered under General Air Permit for Title V Air Curtain Incinerators, which permits up to 30.6 tpy of NOx based on up to 15,300 tons of waste incinerated at the air curtain incinerator per rolling 12-month period (https://eportal.adeq.state.ar.us/webfiles/Air/General%20Permits/2370-AGP-000.pdf): City of Jonesboro - Yard Waste Facility (6.75 tons burned per hour); City of Dardanelle (4 tons per hour burned); Woodson Incorporated, Mabelvale (8 to 10 tons burned per hour); City of Blytheville Public Works (3 to 5 tons burned per hour); Wise Excavation LLC, Paron (8 tons burned per hour); Abide Farms, LLC, Little Rock (7 tons burned per hour); American Composting, Inc., North Little Rock (7 tons burned per hour); R. E. C. Transport, Inc., Dardanelle (7 tons burned per hour); Alternative Waste Management LLC., Mayflower (9 tons burned per hour); Arkansas Department of Transportation, Paragould (0.125 tons burned per hour); Custom Wood Recycling, Inc., Centerville (12 tons burned per hour); City of Wynne Air Curtain Incinerator (10 tons burned per hour); Columbia County Landfill, Magnolia (unspecified throughput); City of Beebe (7.5 tons burned per hour); Dale Payne - P & P Trucking, Casa (8 tons burned per hour); Moore's Dozer Service, Glenwood (9 tons burned per hour).

or cost effectiveness in the record. Yet for solid waste incineration units, EPA is proposing to use those very same factors to potentially exclude waste incinerators. If waste incinerators are excluded on such grounds, EAFs, and the many other units EPA failed to analyze for technical feasibility or cost feasibility must also be exempted. In addition, it is worth noting that any decision by EPA in the final rule to include such units (e.g., EGUs less than or equal to 25 MW, solid waste incineration units, and cogeneration units), would require EPA to perform a reanalysis of overcontrol, since including such units without adjusting the required control limits at other facilities could further exacerbate overcontrol resulting from the Proposed Rule.

G. Controls Will Only be Run on a Seasonal Basis

EPA requested comment on whether any controls installed in order to meet the limits in the Proposed Rule would be run on an annual basis.[140] As a general rule, post combustion controls like SCR will not be operated year-round. As noted above, facilities will only run post-combustion NOx controls during the ozone season when required to and will otherwise limit their use due to the high O&M cost associated with operation of the SCR, and in order to attempt to extend the life of the catalyst given the high cost of replacing the catalyst and how quickly the catalyst can be deactivated under the process characteristics of metal furnaces. Low NOx burners, the other hand, would be operated on a year-round basis since they are integrated into the combustion process.

H. Alternatives to CEMS

EPA requested comment on alternatives to CEMS for ensuring compliance.[141] There are many alternatives to CEMS. For boilers and burner tips, especially, vendor guarantees and known engineering emission factors for natural gas combustion can be used to simply and far more cost effectively track emissions based on simply tracking natural gas usage/throughput. This method may also work for furnaces where NOx emissions derive primarily from coal or natural gas combustion. For any other sources whose NOx emissions cannot be simply derived by tracking natural gas or coal throughput, stack testing should be available as an alternative means of compliance.

More fundamentally, EPA has not demonstrated that CEMS are necessary and appropriate as a means of tracking emissions for non-EGUs. The authority to require any monitoring device must be justified under 42 U.S. Code §7410(a)(2)(B), which states that an implementation plan shall "provide for establishment and operation of *appropriate devices*, methods, systems, and procedures *necessary to*—(i) monitor, compile, and analyze data on ambient air quality." In the past, EPA has required CEMS under Good Neighbor provision implementation plans on the rationale that such precise continuous measurements are necessary when implementing an emission trading program, because as EPA puts it "[t]his type of consistent and accurate measurement of emissions is necessary to ensure each allowance actually represents one ton of emissions and that one ton of reported emissions from one source would be equivalent to one ton

[140] Proposed Rule at 20,141.

[141] Proposed Rule at 20,146.

of reported emissions from another source."[142] But the Proposed Rule expressly decides not to implement a trading program, instead purporting to opt for unit specific performance limits for non-EGU emission units. Moreover, EPA did not even include the cost of CEMS in its cost analysis.[143] Accordingly, EPA has failed to justify both why CEMS are "appropriate" and why they are "necessary" in this wholly different context of unit specific performance rates, especially in light of the fact that other programs (NSPS, NESHAP, PSD, etc.) merely require initial performance testing and periodic confirmatory testing to verify unit specific performance limits, and that EPA wholly fails to provide any persuasive differentiation here in the absence of emission trading.

XIII. The Proposed Rule Endangers National Security by Failing to Consider the Steel Industry's Critical Role in Our National Security and Infrastructure:

A 2017 Presidential Memorandum recently acknowledged that "core industries such as steel" as "critical elements of our manufacturing and defense industrial bases."[144] As a result of the Memorandum, the Department of Commerce initiated an investigation into the effect of steel imports on United States National Security and found that domestic steel production is "essential" for national security applications.[145] This Investigation led to many key findings that the EPA should consider as it evaluates how to effectuate the requirements of the Good Neighbor provision in a reasonable manner.

"[A]cross decades and Administrations, there has been consensus that domestic steel production is vital to national security."[146] "National security" under Section 232 of the 1962 Trade Expansion Act includes both 1) national defense and 2) critical infrastructure needs.[147] Domestic steel production is vital for both. For example, the Department of Defense requires steel to create weapons and other systems needed for our nation's defense.[148]

[142] Proposed Rule at 20,141 (citing 75 FR 45325 (August 2, 2010)).

[143] Non-EGU Screening Assessment at 4 ("The costs do not include monitoring, recordkeeping, reporting, or testing costs.").

[147] *Id.* at p. 13–17, 23 (concluding that domestic steel production is essential for national security); *see also* 19 U.S.C. § 1862 (Section 232 of the Trade Expansion Act of 1962).

[148] 2018 Investigation at p. 24.

Presidential Policy Directive 21 ("PPD-21") also designates sixteen "critical infrastructure sectors," most of which use steel in high volumes.[149] This includes chemical production, communications, critical manufacturing, dams, energy, food production, nuclear reactors, and transportation, water, and wastewater systems. To support these critical infrastructure sectors, the American Society of Civil Engineers estimated that the United States must invest $4.5 trillion in infrastructure by 2025.[150] Steel production is crucial to these goals.

An important consideration to maintaining national security is ensuring that there is sufficient "surge capacity" within the industry, as explained by the Department of Commerce, "it is the ability to quickly shift production capacity used for commercial products to defense and critical infrastructure production that provides the United States a surge capability that is vital to national security, especially in an unexpected or extended conflict or national emergency."[151]

But as written, the Proposed Rule blinks these realities in ways that would have potentially catastrophic consequences for the economy and national security. Even assuming that it was possible to meet the Proposed Rule's unprecedented command-and-control limitations on NOx, installing the required control technologies will cause at least temporary closures of iron and steel facilities all around the nation all at once. "Even temporary idling of steel plants threatens the U.S. steel industry" because of the "significant financial costs with re-opening a steel mill."[152] Halting production can also cause a mill to lose workers, which affects the mill's capacity to produce steel going forward.[153] This often leads to additional costs, such as "specialized worker training and production ramp-up" while mills attempt to re-fill their workforce.[154] And that is the best case scenario; if these newly proposed limits are not feasible, and/or not able to be achieved cost effectively, mills could be forced to permanently close. Even if the new limits are attainable by some facilities, the Proposed Rule's inflexible and uniform command-and-control mandate fails to consider facility specific feasibility and cost variability and thus will likely result in permanent closures, crippling U.S. surge capacity.

Employment and local economies are likewise negatively affected when steel mills are closed, even on a temporary basis. Workers often find other occupations, steel mills to work at, or they remain indefinitely unemployed.[155] If a closure lasts a significant amount of time, workers may lose some of the specialized skills needed for performance. This loss of workers, jobs, and

[154] *Id.*

[155] *Id.*

skills causes substantial difficulties to the steel industry, as recruitment is "typically not easy."[156] And any further workforce constriction would be especially impactful because workforce experience in the iron and steel sector are already diminished.

Further, U.S. steel producers already experience higher production costs than those in other areas of the world. This is, in part, because of environmental and regulatory expenses.[157] For example, prices for hot-rolled steel coil have been higher in the United States than in other countries since 2010.[158] These higher costs incentivize foreign importation of steel, which damages steel production in the United States.

The Proposed Rule will cause iron and steel facilities to temporarily shut down while they attempt to comply with the proposed limits that have never been achieved in practice at any similar units, and thus, even if feasible, will almost certainly result in downtime as facilities and control devices are redesigned and tested. EPA's proposed compliance deadline of the 2026 ozone season risks mass temporary closures of steel mills across the country and across regions. And the supply chain disruptions arising from Covid and subsequent economic conditions, which EPA has not accounted for in setting compliance deadlines, feasibility, or cost analyses, will exacerbate the disruptions to operations that would be caused by these retrofits even in the best of times. This will hinder much of the aforementioned categories: domestic steel production will slow, local economies will be hurt, costs will rise, and the industry may lose skilled workers. Overseas imports of steel will necessarily increase, assuming there is availability. In addition, it is well known fact that steel producers in the United States have far less emissions than most sources overseas that would have to be relied on to make up for the capacity drop in domestic steel production caused by the Proposed Rule.[159] EPA must consider these critical issues as it assesses how to reasonably give effect to the Good Neighbor provision, including taking care in evaluating whether it is actually necessary to regulate the iron and steel industry in order to achieve the reductions needed to satisfy the Good Neighbor provision, and if so whether there are measures with more flexibility (including emission trading, and extended compliance deadlines) rather than rushing into draconian command-and-control measures without any evaluation of facility specific feasibility. Failure to do so threatens to jeopardize our nation's steel industry, infrastructure, and national security.

Global Efficiency Intelligence (November 2019), available from the Harvard's Belfer Center for Science and International Affairs at https://www.belfercenter.org/sites/default/files/files/publication/how-clean-is-the-us-steel-industry-nv.pdf, (concluding that "The U.S. steel industry's final energy and CO2 emissions intensities rank 4th lowest among the countries studied" and showing that the U.S. steel industry is the cleanest and most energy-efficient of the seven largest steel producing countries in the world).

SPECIFIC COMMENTS PERTAINING TO ELECTRIC ARC FURNACES AND ARKANSAS

XIV. EPA Has Identified No Legal Basis for Imposing Emission Unit Specific Limits on the U.S. Steel Facilities in Arkansas.

As discussed in Sections above EPA has no legal basis for regulating U. S. Steel facilities especially those in Arkansas. Notably, the *only* impact relied on for subjecting specifically Arkansas and Mississippi to the stringent non-EGU emission limits in the Proposed Rule is a single maintenance receptor in Brazoria County, Texas which EPA classifies as maintenance status, and projects to still be in maintenance status in 2026. See *Air Quality Modeling Technical Support Document* at D-1 & D-6. The fact that EPA has presented no analysis to support a conclusion that emission units at the U. S. Steel Arkansas facilities (which are located in Osceola, Arkansas, on the far opposite end of the state from TX, about 560 miles from Brazoria, Texas) contribute significantly to impacts at the Brazoria receptor is alone sufficient to require the exclusion of those facilities from the Proposed Rule. But for the sake of thoroughness, U. S. Steel requested the experienced air modeling team at Woodard & Curran to perform modeling to evaluate the significance of BRS's (and EV's, once it commences operation) contribution, if any, to the Brazoria receptor linked to Arkansas under EPA's modeling as demonstrated in the Woodard Report attached as Exhibit A.

First, Woodard & Curran evaluated the impact of BRS/EV on Brazoria based on the scaling factors used by EPA to evaluate the anticipated contributions of industry sectors in developing the Proposed Rule, including the emission units sought to be regulated under the Proposed Rule. More specifically, Woodard updated the emission inventory used by EPA to more accurately reflect the existing BRS facility and the EV facility under construction adjacent thereto,[160] then extrapolated BRS/EV's contribution to the Brazoria receptor using EPA's own state and receptor specific factors, as explained in Woodard and Curran's report. As noted in Table 3 to that report, EPA's calculation methodology would result in an estimate of less than 0.01 ppb contribution from BRS/EV to the Brazoria receptor. This is below the level of significance that EPA used to evaluate the significance of iron and steel facilities to individual receptors (0.01 ppb), and thus is insignificant even by EPA's own interpretation. Moreover, as explained in more detail in a subsequent comment, significance of impacts at a receptor should not be evaluated below 1 ppb, which is far higher than that calculated for BRS/EV. Finally, this calculation method is highly

[160] The BRS scrap to steel products facility in Osceola, Arkansas currently contains two Electric Arc Furnaces (EAFs), which are the only emission units at the facility with a potential to emit more than 100tpy of NOx. On January 31, 2022, AEEDEQ issued BRS a permit to construct and operate a new scrap to steel mill on land adjacent to the existing facility. BRS anticipates transferring the permit for the new mill to Exploratory Ventures (EV), a separate company, but which, like BRS, is owned by US Steel. Although this second facility is not integrated with and operates independently from the existing mill, BRS/EV understands that under existing EPA guidance, the two mills would be considered a single source under Title I of the Clean Air Act. Like the existing facility, the new facility will also have two EAFs, each with a potential to emit more than 100tpy of NOx. The new facility provided notice to AEEDEQ on May 12, 2022, of commencement of construction. Accordingly, the Woodard & Curran model conservatively accounts for all four EAFs in evaluating any potential impact on the Brazoria receptor.

conservative, since the extrapolation factors used in EPA's calculation do not account for where in a state a source is located, and BRS/EV is located in the far edge of the state, over 900 km from the Brazoria receptor.

Second, Woodard & Curran performed HYSPLIT modeling in coordination with AEEDEQ to evaluate impacts to the Brazoria monitor. EPA itself used HYSPLIT in this rulemaking to evaluate environmental justice impacts on a facility specific level for EGUs[161] (though EPA did not use it to evaluate EPA's authority to regulate individual facilities under the Proposed Rule in the first place). EPA has also previously approved the use of HYSPLIT to screen out areas in the similar context of regional haze.[162] HYSPLIT looks at the specific events during which ozone NAAQS exceedances are predicted and can generate a backtrajectory to identify what geographic regions airflows contributed to each specific predicted NAAQS exceedance. This provides more insight than the CAMx model into specific contributions on the specific days that EPA relies on to classify the Brazoria receptor as a maintenance receptor (especially the way that EPA ran CAMx, evaluating only aggregated statewide contributions in general without tagging industries or facilities like CAMx would have allowed EPA to do if EPA had attempted to do so).

HYSPLIT analysis also provides insight as to whether any potential linkages identified by CAMx are consistent and persistent.

EPA's CAMx modeling only looked at five to ten elevated ozone days and did not evaluate where the ozone and precursors arose that contributed to those days (i.e., although EPA looked generally to what states may have contributed, EPA did not evaluate or identify where in a given state contributions originated, since EPA chose to run CAMx without source tags).

To evaluate whether the U. S. Steel facilities in Arkansas could contribute to any of these ozone high events identified by EPA, Woodard & Curran used HYSPLIT to calculate seventy-two hour back-trajectories for the EPA's top-ten CAMx predicted maximum daily 8-hour 2026 ozone events for the ozone monitoring site located in Brazoria, TX. As noted in Woodard & Curran's attached report, the top three ozone days had contributing air parcels originating well outside of Arkansas, or only briefly passing through the very southern section of Arkansas, and in no event originated or passed through the northeastern portion of Arkansas where the U. S. Steel facilities are located. As a result, the U. S. Steel Arkansas facilities did not contribute to any of the events assessed by EPA, and thus cannot be said to significantly contribute to any maintenance issues evaluated by EPA at the Brazoria receptor.

Woodard & Curran is also in the process of performing confirmatory CAMx modeling to determine the source specific contributions to the Brazoria monitor which EPA neglected to evaluate. As EPA is aware, CAMx modeling can take significant time to complete, and although we are diligently pursuing this modeling, it is impossible to complete before the June 21 comment deadline. However, because the necessity of this modeling was created by EPA's failure to perform

[161] Policy Analysis TSD at 67.

[162] 87 Fed. Reg 7734 (Feb 10, 2022).

and/or disclose source-specific CAMx contribution modeling and unreasonably truncated public comment period, and because it bears directly on EPA's authority to regulate U. S. Steel at all under the Good Neighbor provision, EPA must consider this modeling whenever it is completed in determining applicability of any final rule to U.S. Steel facilities without running afoul of the Clean Air Act.[163]

XV. EPA Has Identified No Legal Basis for Regulating the Iron and Steel Industry in Any But Possibly One State, and Certainly Not in Arkansas

EPA has not demonstrated that the Iron and Steel industry in Arkansas (or virtually any state for that matter) is a "type of emissions activity within the State" that will "contribute significantly to nonattainment in, or interfere with maintenance by, any other State."

To begin, as previously noted, EPA's regulation of the iron and steel industry in Arkansas did not even comply with EPA's own oft-referenced "4-step interstate transport framework." Under that approach, EPA, after identifying nonattainment and maintenance receptors (step 1), and screening out any state not contributing at least 0.7ppb to any linked receptor (step 2), was then supposed to "(3) for states linked to downwind air quality problems, identify [] upwind emissions that significantly contribute to downwind nonattainment or interfere with downwind maintenance of the NAAQS; and (4) for states that are found to have emissions that significantly contribute to nonattainment or interfere with maintenance of the NAAQS in downwind areas, implement[] the necessary emissions reductions through enforceable measures."[164] But that is not what EPA did in the Proposed Rule. Rather than evaluate the upwind emissions actually contributing to each screened-in state's linked nonattainment or maintenance receptors, EPA instead just (1) identified industries *nationwide* that contributed at least 0.1pbb to at least one downwind receptor, or 0.01pbb to at least ten receptors[165]; and (2) automatically mandated limits directly on all such sources in each screened-in state, skipping any finding that these sources evaluated on a nationwide basis actually contributed to nonattainment or interfered in maintenance at the linked receptors for each particular state.[166]

Although it may be appropriate as a screening matter to initially identify industry sectors representing potentially significant NOx contributions on a national basis for further review, EPA cannot automatically skip to imposing regulations on all such industry sectors in all screened-in states without some showing that the industry sector at issue is significantly contributing to that particular state's linked nonattainment or maintenance receptors. This is because the Good Neighbor provision from which EPA derives any authority for such regulations only grants authority to prohibit emissions if a "type of emissions activity *within the State*" will "contribute

[163] In fact, using CAMx to simply repeat the modeling that USEPA performed takes longer than the comment deadline allows, particularly in light of how long EPA took to supply the underlying modeling data upon request.

[164] Proposed Rule at 20,041-42.

[165] EPA classified industries that satisfied both these criteria as "Tier 1" and those that satisfied only one as "Tier 2."

[166] Non-EGU Screening Assessment at 2-3, 22-23.

significantly to nonattainment in, or interfere with maintenance by, any other State."[167] Thus, it is arbitrary and capricious to regulate the steel industry nationally rather than regulating the appropriate sources (or at least appropriate industrial sectors) in each state actually contributing to the amount of emissions that need to be reduced from that state to fulfill its Good Neighbor obligations.

EPA also improperly conflated its own screening threshold for whether a state as a whole has a significant enough contribution to require reductions pursuant to the FIP, with the statutory requirement to evaluate significant contributions of a "source or type of emissions activity within the State." As the State of Arkansas rightly notes in it comments in response to EPA's proposed denial of Arkansas' proposed state implementation plan for the 2015 Ozone NAAQS as it relates to Good Neighbor obligations, EPA wholly failed "to show that specific sources in Arkansas are actually contributing significantly to the Harris County monitor or interfering with maintenance of the NAAQS by other receptors, thus EPA is effectively contending that a 1% linkage is the same as a significant contribution, which is not consistent with their guidance or Clean Air Act 110(a)(2)(D)(i). Determination of linkages and significant contributions occurs at separate steps in the four-step analysis. DEQ does not agree that a 1% linkage to an entire state is the same as a significant contribution from a source or emissions activity. The state's obligation is not to eliminate an arbitrary threshold (or to reduce emissions such that a neighboring state that may be its own primary contributor to nonattainment is not overburdened by their own obligations), but to determine if any emissions sources or emissions activity in the state are significantly contributing to a downwind nonattainment receptor or interfering with maintenance of the NAAQS by a downwind state and respond accordingly to mitigate significant contributions."[168]

If EPA had failed to evaluate the contributions of each screened-in industry in a state prior to subjecting it to regulation in that state, then EPA would have 'merely' failed to justify the regulation of such industry in each state. But EPA's failure to comply with statutory requirements is even more unreasonable, arbitrary, and unlawful here, because it appears that EPA *did* perform an evaluation of whether each industry contributed to nonattainment or maintenance issues at each states linked receptors, and then went on to attempt to regulate NOx emissions from each industry sector in each screened-in state despite specifically finding that many industries did not contribute to that state's linked receptors above the industry significance thresholds set by EPA.[169] For instance, EPA's own modeling found that the Iron and Steel industry only contributed to a nonattainment or maintenance receptor above EPA's own significance threshold (0.01ppb) in only one state and that state is not Arkansas, as show below[170]:

[167] 42 U.S. Code § 7410(a)(2)(D)(i)(I).

[168] See Comment submitted by Arkansas Department of Energy and Environment, Division of Environmental Quality, on EPA-R06-OAR-2021-0801-0001, at 22 (April 22, 2022).

Pharmaceutical and Medicine Manufacturing	2	2	300	0.057	0.011	0.003	1	1

Although Table A-3 does not disclose the sole state with impacts from the iron and steel industry above EPA's significance thresholds for industry, the context suggests that state is almost certainly not Arkansas, as those are not among the states where the Non-EGU Screening Assessment identifies large potential reductions of NOx from the iron and steel industry.**171** Thus, EPA's own modeling appears to affirmatively demonstrate that Iron and Steel Industry is NOT a significant contributor to Arkansas' downwind linked maintenance receptor (Brazoria), and it would thus be arbitrary and unlawful for EPA to subject the steel industry in Arkansas and other such states to the Proposed Rule in the face of this specific finding. The same conclusions could be reached for the iron and steel industry in every other state without further analysis with the exception of the single state identified by EPA in the Proposed Rule.

It is particularly important for EPA to correct this approach given its determination that Arkansas may be overcontrolled under the Proposed Rule since their contributions to the Brazoria receptor are predicted to be erased based solely on imposition of controls on Tier 1 industry.[172]

EPA's request for comments on whether to only regulate Tier 1 industries in Arkansas and exempt Tier 2 industries also misses the statutory mark. EPA only has regulatory authority to prohibit amounts of emissions from a "source or other emissions activity" that will "contribute significantly to nonattainment in, or interfere with maintenance by, any other State." Thus, for Arkansas, EPA must consider whether an industry is actually a significant contributor to Arkansas' linked receptors, and it is arbitrary and unlawful for EPA to consider regulating an industry in Arkansas on some other basis (such as whether EPA considers an industry to be "Tier 1" or "Tier 2" as a nationwide matter). For instance, EPA's modeling suggests that for Arkansas, Pipeline Transportation of Natural Gas (a so called "Tier 1" industry) and Pulp, Paper, and Paperboard Mills (a so called "Tier 2" industry) are by far the industries where most of the emission reductions are expected to occur in Arkansas under the Proposed Rule, with potential reductions from Pulp, Paper, and Paperboard Mills dwarfing the amount of all other Tier 1 industries combined (other

---

[171] See Non-EGU Screening Assessment at Figure 2 (identifying only IN, OH, and PA as having ozone season anticipated NOx reductions of more than 100 tons).

[172] Proposed Rule at 20,099.

than "Pipeline Transportation of Natural Gas").[173] Accordingly, EPA should avoid overcontrol and adhere to the statutory text by only regulating industries within a particular state which significantly contribute to that state's linked receptors, rather than by whether EPA happens to classify the industry as "Tier 1" or "Tier 2" on a nationwide basis.

XVI. There are Many Reasons to Conclude that the Proposed Rule Will Result in Impermissible Overcontrol, Specifically With Regard to Arkansas.

The Supreme Court has held that when drafting regulations to enforce the Good Neighbor provision, "EPA cannot require a state to reduce its output of pollution by more than is necessary to achieve attainment in every downwind State or at odds with the 1% threshold the Agency has set" . Moreover, "if any upwind State concludes it has been forced to regulate emissions below the one percent threshold or beyond the point necessary to bring all down-wind States into attainment, that State may bring a particularized, as-applied challenge to the Transport Rule, along with any other as-applied challenges it may have." Notably, these pronouncements were made in the context of an EPA rule which placed statewide emission budgets on states (thus allowing states to challenge those emission budget) and did not impose facility/emission unit level command-and-control limits like the Proposed Rule. By the same rationale, because the Proposed Rule attempts to impose facility/emission unit level command-and-controls on the purported basis of such controls being necessary to fulfill Good Neighbor provisions, the Proposed Rule will be subject to facility level challenges from any facility on the basis that EPA's controls are more stringent than necessary to result in attainment of any downwind receptor to which the facility's state is linked. Accordingly, EPA's statement that any "claim that controls are not necessary to eliminate significant contribution would not suffice to justify an extension" is false; not only would such a claim justify an extension, but it should completely exempt such facilities from the Proposed Rule's limits altogether, since the Good Neighbor provision only grants authority to prohibit emissions "in amounts which will . . . contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any such national primary or secondary ambient air quality standard."

There are many reasons to believe that the Proposed Rule results in impermissible overcontrols, especially with regard to the Brazoria County, Texas receptor which is the only receptor Arkansas is linked to, and thus the only basis EPA has identified for imposing non-EGU limits in Arkansas.[174]

A. Brazoria Receptor Resolves Without Any Reductions from Arkansas and Mississippi.

To begin, the Brazoria County, TX receptor is a maintenance receptor, not a nonattainment receptor. To be sure, the courts have held that the Good Neighbor provision grants authority to prohibit not just amounts that will contribute significantly to nonattainment, but also those amount

[173] Non-EGU Screening Assessment at Table 4.

[174] While U.S. Steels comments in this section is limited to Arkansas, the same arguments could be made as it relates to the State of Mississippi, which is also linked solely to the receptor in Brazoria County, Texas.

that significantly "interfere with maintenance." However, "As the Supreme Court stated, under the 'interfere with maintenance' prong, EPA may only limit emissions 'by just enough to permit an already-attaining State to maintain satisfactory air quality.' If States have been forced to reduce emissions beyond that point, affected parties will have meritorious as-applied challenges."[175]

Brazoria is not just modeled to be a maintenance receptor; it is modeled to consistently improve and to be full attainment and non-maintenance before 2032, as shown below in EPA's own modeling values predicted for the Brazoria receptor in the absence of the Proposed Rule[176]:

Site ID	*ST*	*County*	*2016 Centered Avg*	*2016 Centered Max*	*2023 Avg*	*2023 Max*	*2026 Avg*	*2026 Max*	*2032 Avg*	*2032 Max*
480391004	TX	Brazoria	74.7	77	70.1	72.3	69.1	71.2	67.7	69.8

This is notably different from the scenario addressed by the D.C. Circuit in *Wisconsin v. EPA*, 938 F.3d 303, 326-27 (2019), when the court rejected a generalized argument that a state is necessarily overcontrolled if it is linked to only maintenance receptors yet subjected to the same control levels as states linked to nonattainment receptors. In the first place, that court rejected the claim before it because it was generalized, rather than alleging an as-applied challenge to a specific instance of overcontrol, and because the rule at issue in that case was not expected to fully satisfy upwind States' Good Neighbor responsibilities.[177] But neither of those apply here, to this particularized instance of overcontrol at the Brazoria receptor, in the context of a Proposed Rule designed to fully satisfy upwind States' Good Neighbor responsibilities. Additionally, the court in *Wisconsin* noted that ''the possibility of failing to maintain the NAAQS in the future, even in the face of current attainment of the NAAQS, is exactly what the maintenance prong of the Good Neighbor provision is designed to guard against.''[178] But here, by contrast, the Brazoria County, Texas receptor is not modeled to continue to be a maintenance monitor in danger of slipping to nonattainment, instead it is modeled to trend in the opposite direction, going out of maintenance into full attainment without any application of the Proposed Rule.[179] For this specific receptor, it would thus result in overcontrol to require the draconian NOx reductions required in the Proposed Rule for the states linked only to this receptor.

[176] Air Quality Modeling Technical Support Document at Appendix B, B-3.

[177] *Wisconsin v. EPA*, 938 F.3d 303, 327 (2019).

[178] *Wisconsin v. EPA*, 938 F.3d 303, 326 (2019) (quoting 81 Fed. Reg. at 74,531).

[179] Note also that this conclusion is not affected by potential future industrial growth in upwind states, both because EPA already accounted for anticipated future emission inventory changes, and because any new major sources must undergo PSD evaluations to ensure they do not adversely affect any NAAQS compliance.

B. EPA's Modeling Significantly Underestimates Reductions Associated with the Proposed Rule, Instead Demonstrating that Downwind Linked Receptors are Resolved by Significantly Less Stringent Non-EGU Controls than the Proposed Rule

As explained in more detail below, the modeling used to conclude that the Proposed Rule does not result in overcontrol, specifically at the Brazoria receptor, is based on estimated reductions from each covered non-EGU sector in each state which are far smaller than the emission reductions that would be imposed by the limits in the Proposed Rule. Because EPA's screening assessment shows that sources in Arkansas can reduce emissions sufficiently to bring the Brazoria receptor into full attainment without consideration of numerous excluded facilities (including U. S. Steel's BRS and EV facilities) and without installing SCR on any EAF or other emission units at iron and steel facilities in Arkansas, EPA's decision to nonetheless require stricter emission controls than modeled, on more facilities than modeled, means that the Proposed Rule's emissions limits must result in overcontrol. And because there is substantial overcontrol in Arkansas, all the Proposed Rule's emission limits on non-EGUs (including U. S. Steel's BRS and EV facilities) are arbitrary and capricious because there is no way to determine which limits are necessary to avoid interference with maintenance at the Brazoria receptor.

More specifically, the Proposed Rule relies on the non-EGU Screening Assessment as the basis for the Proposed Rule's evaluation of reductions associated with the Proposed Rule.[180] But EPA drafted this screening assessment before it had performed the air quality modeling underlying the Proposed Rule, and as a result, used a different emission inventory than the emission inventory prepared for the rest of the Proposed Rule.[181] The docket includes a technical support document dedicated to explaining that the non-EGU Screening Assessment was not even designed to capture the facilities that would actually be subject to the Proposed Rule.[182] In EPA's words "Using the emissions thresholds and other factors laid out in the Screening Assessment, EPA generated a preliminary list of non-EGU facilities and emissions units to inform the development of the Proposed Rule. The list of non-EGU facilities and emissions units generated during the Screening Assessment did not constitute a determination by EPA that the identified non-EGU facilities and emissions units are covered by the Proposed Rule. The information on facilities and emissions units provided in the Screening Assessment is likely not a complete listing of the non-EGU

[180] Proposed Rule at 20,056 ("Section III of the Non-EGU Screening Assessment memorandum in the docket for this rulemaking describes EPA's approach to evaluating impacts on downwind air quality, considering estimated total, maximum, and average contributions from each industry and the total number of receptors with contributions from each industry.").

[181] Non-EGU Screening Assessment at 2 n.2 ("We used the [Revised CSAPR Update] air quality modeling for this screening assessment because the air quality modeling for the Proposed Rule was not completed in time to support this assessment.").

[182] See "Technical Memorandum Describing Relationship between Proposed Applicability Criteria for Non-EGU Emissions Units Subject to the Proposed Rule and EPA's 'Screening Assessment of Potential Emissions Reductions, Air Quality Impacts, and Costs from Non-EGU Emissions Units for 2026'" (Memo re Relationship of Proposed Rule to Screening Assessment).

facilities and emissions units potentially covered by the Proposed Rule." In other words, when EPA performed its modeling to evaluate potential emission reductions, EPA did not include the facilities that would be subject to the Proposed Rule, nor the limits that would actually apply to the emission units at those sources.

As a result, this "preliminary list of non-EGUs" notably omits many facilities that would be impacted by the Proposed Rule, and significantly underestimates the emission reductions from some it does include. For instance, in Arkansas, the Non-EGU Screening Assessment included a single emission unit at Nucor-Yamato as the only unit evaluated from the Iron and Steel industry, resulting in reductions of only 6 ozone season tons (15tpy) estimated from the entire iron and steel industry in Arkansas.[183] This absurdly underestimates the reductions that the Proposed Rule would require in Arkansas alone for multiple reasons:

- Even at the one steel mill in Arkansas included in the non-EGU Screening Assessment, the Nucor unit is listed as having annual NOx emissions of only 19tpy.[184] But given that the screening assessment claims to only evaluate emission units with a potential to emit over 100tpy of NOx, this is an error (whether a typo, a selection of the wrong unit at the facility or otherwise). Either way, the Proposed Rule would decrease the permitted lb/ton NOx rate for this facility's (Nucor) EAFs from the current permit limit of 0.38 lb/ton[185] to the Proposed Rule limit of 0.15 lb/ton (i.e., a 0.23 lb/ton reduction). At an average steel production rate of 500 tons per hour[186] times 3,672 hours per ozone season,[187] that represents a potential reduction of up to 422,280 lb (i.e. 211.14 ozone season tons) from this facility's EAFs alone;
- Furthermore, the screening assessment completely omits the existing U. S. Steel's BRS facility (despite the fact that EPA was surely aware of it since EPA used the facility permit as one of the bases for the Annealing Furnace lb/mmBtu limit in the Proposed Rule).[188] At BRS alone, the Proposed Rule would decrease the permitted lb/ton NOx rate for each of the facility's two EAFs by up to 50%, by reducing the current permit

[183] See excel file titled "Screening Assessment Non-EGU Facility and Emission Unit Limits List," which states that "This file provides the list of facilities in 23 states that EPA evaluated in the Technical Memorandum: Screening Assessment of Potential Emissions Reductions, Air Quality Impacts, and Costs from Non-EGU Emissions Units for 2026."; see also non-EGU Screening Assessment at Figure 2 (estimating a total of 1,654 ozone season tons NOx reduction from Arkansas, only 6 of which come from the Iron and Steel industry in Arkansas for) and compare also Proposed Rule at 20,090 (carrying through the non-EGU Screening Assessment without further analysis).

[188] Proposed Rule at 20,145.

limit of 0.3 lb/ton[189] to the Proposed Rule limit of 0.15 lb/ton. At a presumed capacity of 250 tons/hr each,[190] times 3,672 hours per ozone season,[191] that represents a reduction of up to 275,400 lb (i.e. 137.7 ozone season tons) from the facility's two existing EAFs alone;[192]

- U. S. Steel's BRS and Nucor-Yamato are just two of the four Iron and Steel facilities in Arkansas identified by EPA in the modeling used to develop a base case for the Proposed Rule.[193] Accordingly, the screening assessment wholly ignored the reductions the Proposed Rule would force at those other facilities as well.

Notably, this underestimation issue applies beyond Arkansas as well; in fact only one U.S. Steel facility nationwide was accounted for in the screening assessment at all.[194]

By contrast, EPA did include many sources that were not included in the non-EGU Screening Assessment (including U. S. Steel's BRS facility) when later modeling the base case of emissions for the Proposed Rule.[195] *The net result is that EPA accounted for NOx emission from the U. S. Steel BRS* facility when it collectively estimated the impacts of Arkansas as a whole on the Brazoria County, Texas receptor, but not when calculating the reductions expected from non-EGUs from Arkansas as a result of the Proposed Rule. The only conclusion that can be reached is that EPA significantly underestimates the reductions that the Proposed Rule would require.[196] And the fact that this underinclusive modeling was used as the basis for concluding that the Proposed Rule does not result in overcontrol renders EPA's conclusions regarding overcontrol both in general, and especially with respect to Arkansas, arbitrary and capricious.

---

[189] See Big River Steel Permit No. 2305-AOP-R7, available at https://www.adeq.state.ar.us/downloads/WebDatabases/PermitsOnline/Air/2305-AOP-R7.pdf

[190] Big River Steel Permit No. 2305-AOP-R7, at 68.

[191] 153 days in Ozone Season of May-September times 24 hours per day.

[192] As noted, other units, including most notably the LMF, vents to the same canopy as the EAF, and U. S. Steel's BRS facility air permit provides a combined lb/hr rate for each EAF/LMF combination. Accordingly, the amount of emission reductions expected by the rule will in some part depend on whether facilities are required to show decreases from an EAF alone (which is not technically feasible given that any CEMS in the exhaust will be measuring combined emissions of the EAF and LMF), or instead allows compliance to be demonstrated based on the sum of the proposed limits for EAFs and LMFs or some other mechanism. But in any case, the emission reductions would be far above those estimated in the non-EGU Screening Assessment.

[193] See excel file in regulatory docket titled "Summaries of point source emissions used in aqm _att 4 - ptnonipm facility 16 17 18 19 23 26 32 comp 29sep2021".

[194] See excel file in regulatory docket titled "Screening Assessment Non-EGU Facility and Emission Unit Limits List," (identifying only the Clairton Works facility in Allegheny County PA).

[195] See excel file in regulatory docket titled "Summaries of point source emissions used in aqm _att 4 - ptnonipm facility 16 17 18 19 23 26 32 comp 29sep2021" (listing NOx emissions for BRS facility for 2017, 2018, and 2019).

[196] This assumes for the sake of argument that the reductions required by the Proposed Rule are even possible, as addressed herein under the section regarding feasibility.

Rather than take the next step and attempt to estimate what reductions would be associated with the Proposed Rule's command-and-control limits for the iron and steel industry, EPA instead just used the statewide emission reductions from the severely underinclusive non-EGU Screening Assessment as the basis for EPA's estimate of state-by-state expected NOx reductions, which then formed the basis of EPA's conclusion that the rule does not result in overcontrol.[197] Put another way, it appears that EPA's own modeling concluded that even the severely underestimated non-EGU emission reductions would be sufficient to pull the Brazoria County, Texas receptor into attainment.[198] Accordingly, if EPA nonetheless requires the emission limits in the Proposed Rule, which will result in reduction in NOx emissions far above what EPA modeled to result in attainment for the Brazoria receptor (only 6 ozone season tons), EPA is overcontrolling in violation of the Supreme Court's mandate that "under the 'interfere with maintenance' prong, EPA may only limit emissions 'by just enough to permit an already-attaining State to maintain satisfactory air quality.'"[199]

C. The Proposed Rule Fails to Account for Enforceable Closures of EGUs Which Will Result in Overcontrol if Non-EGUs in Arkansas to Subjected to Regulation

EPA fails to account for enforceable closures of multiple EGU units in Arkansas, which, as explained below, will eliminate more NOx contribution from the State of Arkansas than the entirety of all reductions the Proposed Rule seeks from Arkansas. Accordingly, requiring the Proposed Rule's limits for non-EGUs on top of these closures will result in overcontrol.

The following three Entergy power plants are subject to closure pursuant to settlement agreements soon after the 2015 Ozone NAAQS serious attainment deadline of August 2027, and years before the final attainment date under the 2015 Ozone NAAQS of August 2033 for severe nonattainment[200]:

---

[197] Proposed Rule at 20,098 ("using the Ozone AQAT, the EPA first evaluated whether reductions resulting from the selected control stringencies for EGUs in 2023 and 2026 combined with the emissions reductions selected for non-EGUs in 2026 can be anticipated to resolve any downwind nonattainment or maintenance problems (see the Ozone Policy Analysis Proposed Rule TSD for details on the construction and application of AQAT)."); see also Policy Analysis TSD at 34, noting that for non-EGUs, *estimated reductions at receptors was based on the non-EGU assessment* ("In the ozone AQAT, EPA links state-by-state NOX emission reductions (derived from the photochemical model, the non-EGU assessment and/or the IPM EGU modeling combined with the EGU engineering assessment) with 2026 CAMx modeled ozone contributions in order to predict ozone concentrations at different levels of emission levels at monitoring sites.") (emphasis added); *see also* Proposed Rule at 20090 (carrying through the non-EGU Screening Assessment estimates of state-by-state potential NOx reductions without further analysis);

[198] Non-EGU Screening Assessment at Table 3 (concluding that Tier 1 industry reductions estimated from the Screening Assessment alone would result in attainment for Brazoria receptor); see also 20,098 (parroting result of underinclusive Screening Assessment with regard to the Brazoria Receptor).

[199] *EME Homer City Generation, L.P. v. E.P.A.*, 795 F.3d 118, 137 (D.C. Cir. 2015) (quoting *EPA v. EME Homer City Generation, L.P.*, 572 U.S. at 515 n.18).

[200] https://www.arkansasonline.com/news/2021/mar/12/in-settlement-power-plants-to-shut-by-30/

- 50-year-old natural gas units at Lake Catherine by the end 2027 (permitted for 53,000tpy of NOx,[201] actual 2019 ozone season emissions of 173 tons[202])
- Coal-fired White Bluff Power Plant by the end of 2028 (permitted for 53,000tpy of NOx,[203] actual 2019 ozone season emissions of 2,908 tons[204])
- Coal-fired Independence Power Plant by the end of 2030 (permitted for 53,000tpy of NOx,**205** actual 2019 ozone season emissions of 2,845 tons[206]).

Notably, in the Proposed Rule, EPA found that the Proposed Rule constitutes a full satisfaction of Good Neighbor obligations based on only 1,654 *total statewide* ozone season tons reduction from non-EGUs in Arkansas.[207] Accordingly, the closure of White Bluff alone in 2028 or earlier will reduce statewide emissions by almost double the amount that EPA considers sufficient to resolve Arkansas' Good Neighbor obligations, making any control of non-EGUs at that point an impermissible overcontrol unnecessary to satisfy Arkansas' Good Neighbor obligations.

Furthermore, these facilities are much closer to the Brazoria County, Texas and are more likely to interfere with that receptor than are the U. S. Steel BRS and EV facilities.

Although these enforceable closures are not scheduled to occur prior to EPA's proposed 2026 deadline for non-EGUs to comply with the Proposed Rule, that is not a reasonable excuse for failing to take them into account, at least with respect to Arkansas, for at least two reasons.

1. As further discussed herein in the comment section on timing, EPA's selection of a compliance deadline of 2026 is based on deadlines applicable to downwind nonattainment regions, and thus it is not necessary or reasonable to require the same deadline where only attaining maintenance receptors are affected, as is the case with Arkansas which is linked solely to the Brazoria County, Texas receptor, which as previously discussed above, is predicted to be in attainment (but still maintenance) by

[206] See EPA's power plant dataviewer (most recent data from 2019), available at https://www.epa.gov/airmarkets/power-plant-data-viewer

[207] Proposed Rule at 20,090.

2023, to improve even further by 2026, and be full attainment (i.e., no longer maintenance) by or before 2032.[208]

2. The Proposed Rule suggests exempting EGUs from the backstop daily rates otherwise applicable to EGUs in 2026, so long as the EGUs close by 2028,[209] effectively treating 2028 as the effective compliance deadline where EGU closures are concerned.[210] EPA raises many good reasons for considering 2028 given the many changes relevant to air quality that will occur in 2028, including EGU closures in response to new Clean Water Act effluent guidelines and the coal combustion residuals rule under the Resource Conservation and Recovery Act, and the fact that "2028 also represents the end of the second planning period under the Regional Haze program, and thus is a significant year in states' planning of strategies to make reasonable progress towards natural visibility at Class I areas." [211] Notably, EPA proposes to allow EGUs to postpone limits until 2028 even in states actually tied to a nonattainment downwind receptor (unlike Arkansas), which are under an obligation to resolve their linkage by the time of downwind states' attainment deadline pursuant to *Wisconsin v. EPA*.[212] Given all of these emission reductions anticipated in 2028, and EPA's consideration of these factors in postponing compliance deadlines from 2026 to 2028 in the context of EGU closures, EPA should also take into account closures anticipated by 2028 (including the White Bluff plant in Arkansas) in evaluating the need to regulate non-EGUs.

Given the fact that EPA already identified changes in 2028 as reasonable to consider in setting compliance obligations (including even for States that are predicted to have impacts on nonattainment areas beyond 2026), the fact that Arkansas is not linked to any nonattainment receptor that requires an obligation to resolve the linkage by the time of the downwind state's attainment deadline, and the fact that the closure of White Bluff Power Plant in 2028 would alone eliminate more emissions than EPA models are needed from all non-EGUs combined in Arkansas to ensure attainment at the Brazoria receptor, it would constitute impermissible overcontrol of the Brazoria receptor to subject non-EGUs in Arkansas to the Proposed Rule.

XVII. EPA Fails to Demonstrate that the Proposed Limits and the Theoretical Controls They are Based on Are Technically Feasible.

[208] Air Quality Modeling Technical Support Document at Appendix B, B-3.

[209] EPA's flexibility around the 2026 deadline for EGUs also extends to facilities which will not shut down in 2028, as EPA proposes to not require unit specific backstop emission rates until 2027 for facilities that do not already have SCR installed. See Proposed Rule at 20,111-12.

[210] Proposed Rule at 20,122.

[211] Proposed Rule at 20,122.

[212] Notably even EPA relies on not being required to achieve the impossible. See Proposed Rule at 20062 ("implementing good neighbor obligations beyond the dates established for attainment may be justified on a proper showing of impossibility or necessity.").

As explained above in Section II., when applying RACT, which Congress has made the express determination is the appropriate level of control when addressing Ozone NAAQS nonattainment, and which EPA claims it meant to follow in developing the Proposed Rule, EPA must demonstrate that the proposed limits are both technically and economically feasible on a facility and unit specific basis. And even stricter standards like BACT still require an analysis of technical and economic feasibility. And in any case, EPA has an independent "duty to examine [and justify] key assumptions as part of its affirmative 'burden of promulgating and explaining a non-arbitrary, non-capricious rule. . . .'"[213] and EPA may not "promulgate rules on the basis of inadequate data, or on data that, to a critical degree, is known only to the agency."[214] And thus EPA's assumptions regarding feasibility in the Proposed Rule must be adequately justified.

The comments in this section are specifically tailored to EAFs because those are the only furnaces used at U. S. Steel's Arkansas facilities with a potential to emit more than 100tpy of NOx, and thus are the only units the Proposed Rule would apply to, since the Proposed Rule only aggregates emissions for the purposes of applicability in the case of a BOF Shop (which would not apply to an EAF given that EAFs and BOFs are different processes, as noted throughout these comments, and throughout the Proposed Rule and its supporting materials). If EPA changes course in the final rule and expands the applicability of the limits in the Proposed Rule, we reserve our right to challenge such applicability and/or provide additional comments regarding any other such units EPA may extend applicability to. In any case, many of the following comments also apply to the other furnace types covered by the rule since EPA has not conducted an adequate feasibility analysis for any iron and steel industry emission unit sought to be regulated under the Proposed Rule.

A. The Controls EPA Bases the Proposed Iron and Steel Industry Emission Limits on Have Never Been Demonstrated in Practice, and EPA's Analysis of Feasibility is Provides Zero Basis to Conclude that They Could be Technically Feasible.

EPA expressly acknowledges that the emission limits for the iron and steel industry, including but not limited to furnaces, are below anything that has ever been achieved in the industry, expressly noting that EPA reviewed permits to find the best performing sources, then requires reductions below what the most stringent existing permits require. The only basis EPA provides for assuming that such reductions are possible is that EPA "[a]ssumes 25% reduction by SCR" for steel mill EAFs.[215] But none of EPA's underlying documentation or data ever evaluate the technical feasibility of retrofitting SCR on steel mill EAFs, or the level of emission reductions available from such a retrofit on an EAF. Simply put, not everything is equivalent to a coal-fired powerplant even though EPA's technical support document incorrectly makes that assumption.

With regard to the technical feasibility of installing an SCR on an EAF, the Proposed Rule does not point to any steel mills that have successfully installed SCRs on an EAF, nor is U.S. Steel

---

[213] *Appalachian Power Co. v. EPA*, 328 U.S. App. D.C. 379, 135 F.3d 791, 818 (1998).

[214] *Portland Cement Ass'n v. Ruckelshaus*, 158 U.S. App. D.C. 308, 486 F.2d 375, 391-93 (1973).

[215] Proposed Rule at 20,145.

aware of any EAF facility to have successfully done so in the world (and there are good reasons for this, as explained in the following subsection).[216] The BRS facility underwent PSD review in 2013 and the new EV facility underwent PSD review in 2021. BACT analyses were submitted with both applications. EPA provided comments on the draft BRS permit in 2013 but did not comment on the 2021 application. In both instances, the application of SCR was eliminated from consideration because the technology is not technically feasible. Other PSD permits issued to EAFs in recent years, all subject to review and comment by EPA, reach similar conclusions. Furthermore, EPA has specifically concluded in the past that "the use of electricity to melt steel scrap in the EAF transfers NOx generation from the steel mill to a utility power plant. *There is no information that NOx emissions controls have been installed on EAF's or that suitable controls are available*."[217]

EPA is required to "provide a more detailed justification than what would suffice for a new policy created on a blank slate" when it promulgates a "new policy [which] rests upon factual findings that contradict those which underlay its prior policy" and an "Agency may not . . . depart from a prior policy sub silentio."[218] There can be little question that the Proposal both departs from prior positions without rationale, and contradicts factual findings underlying its prior policies:

1. EPA abandons its own edict that each unit must be assessed "on an individual basis to determine whether SCR is a feasible control technology"[219]—EPA has not provided any feasibility analysis for steel mill EAFs generally, let alone for each EAF "based on its site-specific characteristics." In fact, the very document which the Proposed Rule cites as the basis for concluding that SCR will reduce emissions from EAFs[220] expressly states that "This screening assessment is not intended to be, nor take the place of, a unit-specific detailed engineering analysis that fully evaluates the feasibility of retrofits for the emissions units, potential controls, and related costs. We used CoST to identify emissions units, emissions reductions, and costs to include in a proposed FIP; however,

[216] In connection with the preparation of these comments, U.S. Steel consulted extensively with SMS Group, which is one of the world's leading suppliers of technology in the iron and steel industry and is the main technology provider for EAFs and other steelmaking equipment at U.S. Steel's BRS and EV facilities. According to the SMS Group, it is aware of no facilities in the world where SCR technology has been installed to control NOx emissions from steel mill EAFs. Black and Veatch's discussion with SCR vendors confirms this conclusion.

[217] Alternative Control Techniques Document – NOx Emissions From Iron and Steel Mills (EPA-453/R-94-065) (September 1994), at pg. 5-23; See also Point and NonPoint NOx Menu of Control Measures, at 15-16 (2012) (only identifying post combustion NOx controls as feasible for certain furnace types in the iron and steel industry, but not for electric arc furnaces). Note that there are natural gas burners used to assist the process, but these are responsible for less than 30% of the NOx emissions associated with an EAF, with the bulk of emissions being associated with the electric arc process, which is not a combustion process. Furthermore, the burners used are already low-NOx such that further emission reductions from burner replacements cannot be assumed to be feasible.

[218] *FCC v. Fox TV Stations, Inc.*, 556 U.S. 502, 515-16, 129 S. Ct. 1800, 1811 (2009).

[219] EPA Comments to Cost Estimate Manual, SCR Chapter, pg. 9, 13-14.

[220] Proposed Rule at 20,146 citing the "non-EGU screening assessment" as the basis for estimated "reductions of 20 to 50 percent" for iron and steel mills.

CoST was designed to be used for illustrative control strategy analyses (e.g., NAAQS regulatory impact analyses) and not for unit-specific, detailed engineering analyses."[221]

2. EPA has not provided any justification for its newfound belief that SCR is a feasible control for steel mill EAFs. Specifically, the Proposed Rule does not detail what if any relevant change to EAF or SCR technology has occurred since 1994 which would make SCR technically feasible NOx control for an EAF. [222]

3. EPA has historically refused to adopt unproven applications of technologies even in other programs where EPA has broad authority to require NOx reductions.[223]

Despite these past practices and findings, EPA nonetheless skips any analysis of unit specific feasibility, or even technical feasibility for EAFs in general, while nonetheless imposing limits that expressly presuppose such feasibility.

With regard to emission reductions expected, the Proposal purports to base its assumption of "reductions of 20 to 50 percent" for iron and steel mills "on the selection of SCR, SNCR, and burner replacement in the non-EGU screening assessment."[224] But the non-EGU screening assessment never assessed emission reductions associated with installation of an SCR at a single EAF.[225] And for newer facilities like U.S. Steel's BRS or EV facilities, which have undergone BACT review in recent years, low NOx burner technology is already in place. EPA does not explain or acknowledge this disconnect and provides no other rationale for why an SCR (or other technologies) can be assumed to reduce NOx emissions on an EAF by more than 20%-50%. Because the Proposed Rule's assertion that steel mill EAFs can achieve required emission limits by installing SCRs or other technologies is unsupported by the screening assessment on which EPA purports to base its assumptions, the Proposed Rule is arbitrary and capricious since "the agency has failed to 'examine the relevant data' or failed to 'articulate a rational explanation for its actions.'"[226] Nor does EPA attempt any facility or emission unit level analysis of whether the

Reg. 67,112, 67,151 (December 19, 1996) (In the context of setting NOx emissions under the Title IV Acid Rain program, finding "The AEP demonstration of retrofitting a two-stage OFA system to a wet bottom boiler has not proved to be successful as yet. Thus, EPA does not find this technology to be the best system of continuous emission reduction for wet bottom boilers and is not using the technology to establish a NOx emission limit for wet bottom boilers in this rulemaking.")

[224] Proposed Rule at 20146; Non-EGU Sectors TSD at 43.

[225] Non-EGU Screening Assessment at Table 6 (only identifying SCR as a control technology evaluated for BOF, Blast Furnace, and Sintering processes in the Iron and Steel Industry). In fact, Table 6 reveals that the non-EGU Screening Assessment did not include analysis of <u>any controls</u> at any EAF at all (unless the EAF was for some reason classified as "Industrial Process – General" of "Industrial Process – Other Not Classified," neither of which was evaluated for SCR in any case).

[226] *Genuine Parts Co. v. EPA*, 890 F.3d 304, 311-12, 435 U.S. App. D.C. 338 (D.C. Cir. 2018) (quoting *Carus Chem. Co. v. EPA*, 395 F.3d 434, 441, 364 U.S. App. D.C. 339 (D.C. Cir. 2005)).

technology required would actually reduce NOx emissions. This is in notable contrast to prior rulemakings, where EPA at least attempted to consider levels of emission reductions that might be achieved at individual non-EGU facilities in light of the feasibility of control installation if they were subjected to Good Neighbor regulations.[227] EPA's failure to conduct emission unit-specific assessments of technically feasible emission reductions for the non-EGUs EPA subjects to the emission limits under Proposed Rule is particularly arbitrary in light of EPA's treatment of California's EGUs, which EPA proposes to exempt from the Proposed Rule based on a facility or emission unit specific analysis that significant additional potential emission reductions from the relevant EGU would not be technically feasible,[228] an analysis EPA refused to conduct for any other facility nationwide.

Finally, it is not even clear that EPA based its assumption regarding EAF lb/ton limits currently achieved in practice on a review of solely facilities that have EAFs. For most of the other iron and steel furnace types, EPA identifies which facility permit or state RACT limit EPA reviewed and used as a basis for identifying a lb/ton efficiency limit currently achieved for that furnace type, which EPA assumes could be lower by use of SCR.[229] But for EAFs, EPA does not identify any facility permit by name, instead the Proposed Rule vaguely states that EPA found "Example permit limits at around 0.2 lb/ton" [230] The Non EGU Sectors TSD further states that, for EAFs, "EPA considered a range of baseline emission data and permit limits from mini mills, integrated iron and steel facilities, and ferroalloy facilities ranging from 0.20 lb/ton to 0.35 lb/ton."**231** Because integrated iron and steel facilities generally use Blast Furnaces and BOFs and not EAFs, and ferroalloy facilities do not use EAFs[232] this suggests that EPA looked at non-EAF units as a basis for setting the NOx emission limits for EAFs in the Proposed Rule.[233] To the extent that EAFs at a given facility have an emission rate higher than 0.2 lb/ton identified by EPA, then the SCR control technology proposed by EPA, even if technically feasible to install (which it is not), would have to be shown to be capable of reducing emissions by greater than 25% to justify EPA's assumption that the proposed limits are possible to achieve. For instance, at a facility

[228] Proposed Rule at 20,088.

[229] See Proposed Rule at 20,145.

[230] See Proposed Rule at 20,145.

[231] Non-EGU Sectors TSD at 43.

[232] See Proposed Rule at 20181 (defining an "Electric Arc Furnace" as only those furnaces "equipped with electrodes used to produce carbon steels and alloy steels primarily by recycling ferrous scrap.").

[233] To the extent EPA based the 0.2 lb/ton limit off of the Title V Operating Permit issued to Timken Faircrest in North Canton, OH, there is no such enforceable limit in this permit. The permit establishes a monthly NOx emission limit of 10.833 tons/month averaged over a 12-month basis. See http://wwwapp.epa.ohio.gov/dapc/permits_issued/1448372.pdf . Such a limit is not the same as a 0.2 lb/ton limit averaged over a 3-hour or even 30-day period, particularly since the compliance demonstration is based upon a stack test performed in 2006 (as opposed to the Proposed Rule, which would require compliance demonstrations based upon CEMs).

achieving 0.3 lb/ton with low NOx burners, an SCR would have to be capable of reducing NOx by at least another 50% for the 0.15 lb/ton limit to be possible to achieve.

In addition, while it is true that EPA was able to avoid considerations of unit specific feasibility in prior Good Neighbor rulemakings and simply focus on "fleet average" characteristics, that is only accurate because all such prior rulemakings were based on emission trading schemes with statewide budgets, rather than imposing emission limits on a unit specific basis as it now proposes to do for the first time ever under the Proposed Rule. Even EPA's prior rulemakings acknowledged that that "unit-specific short-term emission rates pose significant implementation and rulemaking challenges," and if EPA were "to choose to implement a unit-specific emissions rate regime for implementation, the compliance flexibility afforded by emissions trading would not be available and it would not be possible to rely on fleet average information to the same extent . . . ."[234] . Thus, EPA cannot evade unit specific feasibility analysis by merely pointing to past rulemaking while ignoring this fundamental difference between an emissions trading program and command-and-control emission limits it seeks to impose on the iron and steel industry. This is especially important where proposed limits begin reaching or exceeding limits of technological feasibility. If EPA wishes to impose emissions limits on a unit specific basis under the Good Neighbor provision of the Clean Air Act, at a minimum, EPA must address the technical feasibility of emission limits on an emission unit basis.[235]

---

[234] *Id.*

[235] The comments in this section are specifically tailored to EAFs because those are the only emission units used at U. S. Steel's Arkansas facility (BRS and the EV facilities) with a potential to emit more than 100tpy of NOx. However, these same comments also apply to the other furnace types covered by the Proposed Rule since EPA has not conducted any adequate feasibility analysis for any such furnaces, only identifying a coal-fired annealing furnace as the only furnace type at which an SCR has been demonstrated, and not attempting any facility level feasibility analysis for any furnace type or facility subject to the Proposed Rule. And EAFs are not at all like annealing furnaces. Furthermore, other furnace types have their own unique considerations that would make SCR, SNCR or other controls like low NOx burners not technically feasible; for example, NOx emissions from vacuum degassers are caused only by the control device itself (the flare), and involve very low total emissions of NOx (permitted at 2tpy at U. S. Steel Arkansas facilities), and SCR (or SNCR or any other post-combustion controls) has not been demonstrated to be technically possible let alone feasible or cost effective on either a flare or on such low emission levels. Additionally, the tunnel furnace at the U. S. Steel BRS facility operates at a far higher temperature than SCR can feasibly operate at (over 1000 degrees) (and under what an SNCR can accommodate), and iron oxide scale generated from the slabs rolling over the rollers would bombard any catalyst installed, plugging it and reducing its efficiency and life, and furthermore each time that the door opens to accept a new shuttle there is a sudden increase in air input, causing discontinuity to fluegas airflow which can in turn lead to additional ammonia slip, and even if possible to retrofit, any retrofit would not be cost justified for a source that is under 100tpy of potential NOx emissions, and is already equipped with low-NOx burners such that further reductions based on burner replacement cannot be assumed. Furthermore, although some annealing furnaces may be larger stacked units, many annealing furnaces such as those at the U. S. Steel Arkansas facilities are small (under 6 tpy potential to emit) and only intermittently operated batch processes that are not even stacked, and thus are not amenable to control by CEMS, SCR or other post-combustion control. Also, to the extent SCR is not technically feasible to install in the vents from the EAF, they will likewise necessarily not be feasible to install for any of the small supporting units in the meltshop (including ladle/tundish preheaters, and ladle metallurgy furnaces), since those units do not have independent stacks and instead vent to the same canopy collecting emissions from the EAF. To the extent EPA makes any applicability

B. *There are Many Reasons to Conclude that SCR is Not Technically Feasible for EAFs, and/or Would Not Result in the Emission Reductions Assumed by EPA.*

There are good reasons why no EAF has ever demonstrated SCR controls in practice – there are many technical issues which could either render installation infeasible or would prevent the SCR from generating the emission reductions it may have in other contexts. This section summarizes many such issues and is informed by BRS' discussions with one of the largest worldwide designers and providers of EAF technology, the SMS Group, and a principal designer of EAF technology utilized at the BRS and EV facilities ("BRS/EV facility"). Neither the SMS Group nor the SCR vendors consulted by Black & Veatch are aware of any EAF steelmaking facility in commercial operation that has successfully installed SCR to control NOx. The attached memorandum from Black & Veatch, an engineering firm with actual experience designing and installing SCR systems at EGUs, also includes more detailed and technical critiques of the technical and economic feasibility of installing SCR at the BRS/EV facility and we hereby incorporate that memorandum by reference.

EAFs are a fundamentally different process than the EGUs at which SCR has been demonstrated. For one, unlike the relative continuous process associated with EGUs, an EAF is a batch process, with emission spikes when the furnace is charged with scrap and the electrodes bore-in initiating the arc (e,g, tapping), as well as emission profile and temperature shifting throughout the melt cycle. This matters because an SCR requires stable gas flow rates, NOx concentrations, and temperature to effectively reduce NOx. The temperatures of the EAFs at the BRS/EV facility exhausts will vary widely over the melt cycle, and the gas flow rates, and NOx concentrations will exhibit a wide amplitude, both of which may limit the efficiency of or damage the catalyst in an SCR. Furthermore, an EAF is not a combustion process, but instead primarily relies on electricity to melt metal scrap,[236] meaning that the emission profile of the process is different than the emission profile associated with combustion of fossil fuels, notably including sulfur dioxide and many metals and materials that are incompatible with the SCR, because certain elements present in EAF emissions, such as iron, arsenic, sodium, potassium, nickel, chrome, lead and zinc and potentially others, can react with platinum catalysts to form compounds or alloys which are not catalytically active. These reactions are termed "catalytic poisoning."[237] Furthermore, any solid material in the gas stream can form deposits and result in fouling or masking of the catalytic surface. Fouling occurs when solids obstruct the cell openings within the

changes in the final rule, we reserve the right to challenge application of any such limits or controls to non-EAFs as well since EPA has not shown them to be technically feasible.

[236] While some low NOx natural gas burners are used to support the EAF, the majority of emissions from the process are not attributable to these burners (but rather are attributable to thermal NOx). Accordingly, although low-NOx burners can have a marginal impact on emissions, they can only control a small percent of the EAF's total NOx emissions.

[237] EPA has previously acknowledged this to be an issue. See EPA Comments to Cost Estimate Manual, SCR Chapter, pg. 15 "We agree with the commenter that SCR systems applied to units with high dust loading and high concentrations of sulfur and other compounds may deactivate SCR catalysts and hence increase the capital and operating costs of an SCR."

catalyst. Masking occurs when a film forms on the surface of catalyst over time. The film prevents contact between the catalytic surface and the flue gas. It is infeasible to install an SCR upstream of the baghouse which collects these metals and particulate matter, because the SCR catalyst would be bombarded with all these elements which it is not equipped to handle, reducing its efficiency and at best requiring frequent changing of the catalyst. Furthermore, there may be potential for entrained moisture and or condensable emissions that could be detrimental to the catalyst if a leak were to occur from the tubular section or when temperatures and moisture conditions are unfavorable during cycling of systems. The ability of poisoning and fouling to make SCR technically infeasible is not theoretical. As noted in the attached Black & Veatch report, plugging due to sodium in fluegas has prevented efficient operation of SCR during pilot studies at the Coyote Station in North Dakota, and BRS has high levels of sodium in its fluegas (particulate matter from the EAF captured by the baghouse has 8,080 ppm sodium).[238] And courts have upheld BACT determinations, even in the powerplant context, that SCR is technically infeasible where there are fluegas elements including high levels of sodium and potassium likely to jeopardize SCR operability.[239] This is particularly true of EAFs, which typically have high pre-baghouse particulate matter in the fluegas, as compared to coal fired power plants.

Furthermore, the SCR requires operating temperatures between 480°F (250°C) and 800°F (427°C) of the gas stream at the catalyst bed, in order to carry out the catalytic reduction process. But these temperatures are incompatible with the BRS/EV facility's baghouses which requires the inlet to be dropped down to below 266°F (130°C) or the baghouse could catch on fire. This represents the maximum peak temperature at the spark arrestor prior to the baghouse, with temperatures at other times being far lower accordingly. Furthermore, cooler gas makes the baghouse more effective, since the cooler the gas, the more the metals convert from gas to solid phase preventing them from bypassing the baghouse. In order to regulate the inlet temperature to the baghouse, BRS and EV facilities have cooling systems for the ductwork between each EAF and the associated baghouse. The EAF exhaust temperature must be reduced through a significant length of special tubular water cooled duct i to reduce temperatures sufficiently to avoid damage to downstream components and especially the baghouse. These cooling systems are thus also incompatible with installing an SCR prior to the baghouse since cooling systems must remain to prevent temperatures from compromising the baghouse or interfering with reductions in particular matter, but the resulting cooling results in a temperature outside of SCR operating range.[240]

[239] *See e.g. United States v. Minnkota Power Coop., Inc.*, 831 F. Supp. 2d 1109 (D.N.D. 2011).

[240] Notably this temperature issue also definitively rules out SNCR as technically. infeasible as well, since SNCR requires a far higher operating temperature than even SCR, and an even lower control efficiency. See EPA technical bulletin-Nitrogen Oxides (NOx), Why and How They Are Controlled, at 18, EPA 456/F-99-006R (November 1999) (noting SNCR must be operated at 900°C and 1100°C window).

The only point at which the temperature is not below the operating range of an SCR is the very opening of the EAF duct prior to cooling the fluegas, but that is above the temperature for an SCR (around 1,200 to 1,300°F), and any attempt to cool the temperature at the entrance to the EAF duct, such as through the use of tempering fans, would increase the flowrate through the duct and into the baghouse, which also raises a host of feasibility issues. Specifically, use of tempering fans, and/or any pressure changes caused by the SCR and associated equipment risks jeopardizing the facility's existing pollution control equipment, because the EAFs and pollution control system (baghouse) are designed around specific parameters such as flowrate and pressure drop, and any increase in those parameters could at minimum decrease the life of the bags in the baghouse, and at maximum could result in failure of system components.[241] In addition, the tempering fans, SCR and other new equipment would increase electrical demand at the BRS/EV facility, decreasing efficiency and significantly increasing indirect emissions e.g., NOx, SO2, PM, greenhouse gases, etc. associated with the substantial increase in electricity consumption to operate the SCR and associated equipment and additional flue gas cooling systems, and that assumes that sufficient electric capacity and related equipment to transfer such energy loads is available or otherwise is not in excess of current design capacities.

Critically, as noted in the attached Black & Veatch report, available space is very limited between the EAF and the baghouse and likely would prevent an SCR and associated retrofit equipment being installed anywhere upstream of the baghouse, much less by the entrance to the EAF duct. EPA has previously acknowledged that these spatial constraints can pose obstacles to making an SCR installation work.[242]

Likewise, there are also spacing, and structural design and support limitations that may limit the feasibility of installing an SCR into the stack post-baghouse. Specifically, concrete infrastructure post-baghouse including stack foundation and blower house are substantial installations and the existing as-built design restricts access to the exhaust flow. As noted in the attached Black and Veatch report, there is insufficient space between the ID fan and the stack for the SCR, let alone the booster fan that would likely be necessary to maintain pressure, so any installation would require new structural supports, stack breaching, and the new ductwork would

---

[241] Attempting to cool fluegas by injecting water into the flue gas rather than using a tempering fan would be inefficient because this cooling method is already done (BRS) and will be done, once operational (EV) to lower temperatures to protect the baghouse, but the target temperature for cooling the flue gas for the SCR is different than for protecting and ensuring optimum pollution control efficacy of each baghouse and, as a result, the existing system cannot be used for both purposes, and it is not clear whether it would be possible to design the system to accomplish these two different temperature goals solely through water cooling in the space available.

[242] See EPA Air Pollution Control Cost Manual, edition 6, EPA/452/B-02-001 (Jan. 2002) at section 2.5.4.2 ("an SCR reactor can occupy tens of thousands of square feet and must be installed directly behind a boiler's combustion chamber to offer the best environment for NOx removal. Many of the utility boilers currently considering an SCR reactor to meet the new federal NOx limits are over thirty years old- designed and constructed before SCR was a proven technology in the United States. For these boilers, there is generally little room for the reactor to fit in the existing space and additional ductwork, fans, and flue gas heaters may be needed to make the system work properly.").

require multiple turns that would increase the pressure drop the booster fan would have to provide, and increase power demands, further exacerbating power capacity issues.

Assuming for the sake of argument that an SCR could be designed to be installed after particulate removal by the baghouse to avoid some of these prohibitive conditions, a different type of technical feasibility problem is entailed, because even if an SCR could be installed, the SCR would risk significantly *increasing* emissions, such that the emissions reductions anticipated would not be possible, or may be much smaller than estimated by EPA. This is because the fluegas exiting the baghouse is typically below 200°F, far below SCR operating range. That means that the fluegas would have to be heated post-baghouse by a significant temperature (at least 300°F in a short period of time), requiring significant additional energy, likely from natural gas combustion and associated electricity needs, which in turn would increase the very NOx emissions the SCR is designed to control, as well as increasing greenhouses gas, VOC, CO, SO2 and PM emissions. These increases may be significant as described in the following section, especially compared to the relatively low NOx reductions an SCR would accomplish even if able to run efficiently.

In addition to any increased emissions caused directly by new combustion sources and indirectly due to increased power consumption, unreacted ammonia would also be emitted to the environment as ammonia slip, as described in the following section. Furthermore, formation of ammonium salts can readily foul the catalyst section, resulting in reduced efficiency and increased back pressure, and ammonium salts would be emitted as PM10/PM2.5. And installation after the baghouse system means that these ammonia and ammonium salt emissions would be completely uncontrolled, creating potential compliance and attainment concerns with the PM2.5 emissions limits and NAAQS, respectively. On the other hand, installation of SCR prior to the baghouse system would contaminate the fly ash in the baghouse with ammonia, and as EPA has recognized, "the ability to sell the fly ash as a secondary product is affected by its ammonia concentration."[243] If this compromises BRS' ability to recycle its baghouse dust by resale to reclamation, recycling, or reuse facilities as is BRS' current practice, then the installation of SCR would create a new unrecycled hazardous waste stream. Furthermore, as EPA has also recognized, "ammonia-sulfur salts can plug, foul, and corrode downstream equipment such as air heater, ducts, and fans" thus endangering the existing pollution control system.[244]

Additionally, even if SCR technology could be installed post baghouse, the SCR would have issues with catalyst poisoning due to sulfur, as SO2, reacting with the SCR regardless of the placement of the SCR (impeding technical feasibility) unless desulphurization technology can also be installed (which would entail both its own set of technical feasibility issues in addition to significant additional costs not considered by EPA).

Furthermore, as discussed in the attached Black & Veatch report, stack testing at the U. S. Steel BRS facility shows a NOx concentration in fluegas near the lower limit of what concentration can be controlled by an SCR. According to EPA's own analyses, "Low NOx inlet levels result in

[243] EPA Air Pollution Control Cost Manual, edition 6, EPA/452/B-02-001 (Jan. 2002) at section 2.2.6, page 2-28.

[244] EPA Air Pollution Control Cost Manual, edition 6, EPA/452/B-02-001 (Jan. 2002) at section 1.2.3, page 1-12.

decreased NOx removal efficiencies"[245] an SCR is generally only expected to control 70% of emissions at a part per million ("ppm") loading as low as 20 ppm (putting aside temperature, fouling, poisoning, plugging, and other such issues which could decrease efficiency and/or degrade the catalyst). [246] And we are unaware of any vendor that will guarantee removal efficiency at all much below 5 ppm NOx. These limitations on control efficiency are further exacerbated by the temperature issue, since temperatures on the low end of SCR operability also significantly decrease SCR efficiency as compared to higher temperatures.[247]. Given the combination of very low NOx concentration loadings, and low temperatures, the control efficiencies presumed by EPA in the Proposed Rule are simply not technically feasible.

C. Emission Increases Associated With Installation of SCR.

Based on the engineering review conducted by Black & Veatch and discussed above, the exhaust gas temperature from an EAF, prior to the dedusting baghouse / after the baghouse, is the vicinity of 200 degrees Fahrenheit (F), thus requiring additional equipment to be installed to raise the exhaust gas temperature by at least 300 degrees F to reach the minimum operability range of 500 degrees F for an SCR, as would be required for just 50% NOx removal efficiency (not taking into account the NOx concentration, airflow variability, and poisoning/fouling/plugging issues discussed above). To support reheating of the exhaust gas by an additional 300 degrees F will require the installation of a heating devices, which will consist of the installation / operation of a natural gas fired burner(s).

The amount of energy required to heat the EAF dedusting exhaust air by 300 degrees F can be calculated with the following equation:

- British Thermal Units (BTU) Output = Temperature rise multiplied by (X) cubic feet per minute X BTU per pound per degree F X the density of air at 200 degrees F X 60 minutes per hour.
    - Temperature rise required is 300 degrees F.
    - Exhaust gas flow from an EAF is on average approximately 1,300,000 standard cubic feet per minute (SCFM) from a dedusting system. Actual flow rate (ACFM) does vary based on temperature and other parameters.
    - Specific heat of air at 200 degrees F is 0.24 BTU per pound per degree F.
    - The weight per cubic foot of air is 0.061 (pounds / cubic foot)(lbs/ft3)).
- BTU Output = 300 degrees F. X 1,300,000 cubic feet per minute X 0.24 BTU per pound, per degree X 0.061 lbs/ft3 X 60 minutes / hour = 342.5 MMBtu/hour.

[245] EPA Air Pollution Control Cost Manual, edition 7 (June 2019) at section 2.2.2.

[246] EPA, Clean Air Technology Center Products, Air Pollution Technology Fact Sheet: Selective Catalytic Reduction (2003), available at https://www.epa.gov/catc/clean-air-technology-center-products.

[247] EPA Air Pollution Control Cost Manual, edition 7 (June 2019) at section 2.2.2 figure 2.2.

To generate the 342.5 MMBtu/hour needed to heat the exhaust gas by 300 degrees F, and assuming the heating value of natural gas is 1,000 BTU per cubic foot, you would need 342,500 cubic feet per hour of natural gas. Combusting that additional natural gas will cause a release of NOx emissions (among other pollutants) during the process of combusting that natural gas in the heating burner(s).

The amount of NOx emissions that can occur when combusting 342,500 cubic feet of natural gas can be calculated using the AP-42 emission factors EPA has published for the purpose of calculating emissions of pollutants from combustion of natural gas.[248] An emission factor is a representative value that attempts to relate the quantity of an air pollutant released to the atmosphere with an activity associated with the release of that air pollutant. These factors are usually expressed as the weight of air pollutant divided by a unit weight, volume, distance, or duration of the activity emitting the pollutant (e. g., kilograms of particulate emitted per megagram of coal burned). Such factors facilitate estimation of emissions from various sources of air pollution. In most cases, these factors are simply averages of all available data of acceptable quality and are generally assumed to be representative of long-term averages for all facilities in the source category (i. e., a population average).

Section 1.4 of AP-42 provides emission factors for quantifying the emissions of NOx, as well as other regulated air pollutants based in the combustion of natural gas expressed in either pounds per MMBtu or pounds per standard cubic foot of natural gas combusted. Tables 1.4-1 and 1.4-2 provided emission factors for various regulated air pollutants. Those emission factors are summarized in the table below:

Combustion type	**Regulated Air Pollutant**	**Emissions Factor (lb/10^6 standard cubic foot)**
Large Wall-Fired boilers – Controlled With Low NOx Burners, > 100 MMBtu / Hour Heat Input	Oxides of Nitrogen (NO_x)	140
Large Wall-Fired boilers – Controlled With Low NOx Burners, > 100 MMBtu / Hour Heat Input	Carbon Monoxide (CO)	84

[248] See "Compilation of Air Pollutant Emissions Factors – Volume I: Stationary Point and Area Sources", dated January 1995. The Emission Factor And Inventory Group (EFIG), in the U. S. Environmental Protection Agency's (EPA) Office Of Air Quality Planning And Standards (OAQPS), develops and maintains emission estimating tools used in developing emission control strategies, determining applicability of permitting and control programs, ascertaining the effects of sources and appropriate mitigation strategies, and a number of other related applications. The AP-42 series is the principal means by which EFIG can document its emission factors. These factors are cited in numerous other EPA publications, and electronic data bases, but without the process details and supporting reference material provided in AP-42 and are generally relied on by EPA when source specific testing or CEMS are unavailable.

Large Wall-Fired boilers – Controlled With Low NOx Burners, > 100 MMBtu / Hour Heat Input	Carbon Dioxide (CO_2e)	120,000
Large Wall-Fired boilers – Controlled With Low NOx Burners, > 100 MMBtu / Hour Heat Input	Particulate Matter <2.5 Microns ($PM_{2.5}$)	7.6
Large Wall-Fired boilers – Controlled With Low NOx Burners, > 100 MMBtu / Hour Heat Input	Sulfur Dioxide (SO_2)	0.6
Large Wall-Fired boilers – Controlled With Low NOx Burners, > 100 MMBtu / Hour Heat Input	Volatile Organic Compounds (VOCs)	5.5

To estimate the potential emissions of the above listed regulated air pollutant, the emission factor expressed in pound per million cubic standard feet of natural gas is multiplied by the quantity of natural gas combusted in an hour to get pounds of that air pollutant per hour and then the amount of natural gas consumed in a year to get pounds per year or commonly expressed as tons per year. Provided in the table below is an estimate of the additional air pollutants that would be released in the atmosphere based on installation of natural gas burners to heat the EAF exhaust air by 300-degree F, to allow for SCR to operate at even minimum effectiveness.

Regulated Air Pollutant	**Emissions Factor (lb/10^6 standard cubic foot)**	**Estimated million (10^6) standard cubic ft per of hour of Natural Gas)***	**Estimated Lbs Per Hour Emission Rate**	**Estimated Tons Per Year****	**Estimated Tons Per Ozone Season*****
Oxides of Nitrogen (NO_x)	140	0.3425*	47.95	210.0	87.5
Carbon Monoxide (CO)	84	0.3425*	28.77	126.0	52.5
Carbon Dioxide (CO_2e)	120,000	0.3425*	41,100	180,018	75,007.5
Particulate Matter <2.5 Microns ($PM_{2.5}$)	7.6	0.3425*	2.6	11.4	4.75
Sulfur Dioxide (SO_2)	0.6	0.3425*	0.21	0.92	0.38

Volatile Organic Compounds (VOCs)	5.5	0.3425*	1.88	8.23	3.4

* As noted above the amount of natural gas estimated on an hourly basis to heat exhaust gas up by 300 degrees F is 342,500 standard cubic feet per hour. Expressed in lbs/106 standard cubic foot would be 0.3425 lbs/million standard cubic foot.

** Assumes operation 24 hours a day 365 days per year.

***Tons per year multiplied by 5/12 to reflect five months of ozone season.

It is important to note, that the above estimated emissions of regulated air pollutants are additional amounts of these air pollutants that would be generated / released to the atmosphere based on the required heat the EAF dedusting exhaust gas by 300-degree F to allow for SCR to operate. An additional 250-degree F raise in the temperature would be required so that the SCR could operate at the optimum temperature (i.e., to achieve a 90% reduction in NOx emissions), which is around 750-degree F in NOx emission levels. The amount of energy required to raise that temperature would require the natural gas volume to be increased by almost a factor of two. In that case, the projected emissions rates would also increase by a factor of approximately two. Note also that this is an estimate of the increased air pollutant emissions per EAF and would thus need to be multiplied by each EAF to which SCR is applied which for the case of the BRS/EV facility, would be four (4) times to reflect four (4) EAFs.

Notably, as explained elsewhere in these comments, the Proposed Rule would decrease the permitted lb/ton NOx rate for each of the BRS/EV EAFs by up to 50% by reducing the current permit limit of 0.3 lb/ton to the Proposed Rule limit of 0.15 lb/ton. At a presumed capacity of 250 tons/hr for each EAF, times 3,672 hours per ozone season, that represents a reduction of up to 137,700 lb (i.e., 68.85 ozone season tons) per EAF. Comparing these maximum potential reductions (68.85 ozone season tons) to the potential NOx increases (87.5 ozone season tons), it appears that the changes to an EAF dedusting exhaust gas temperature necessary to enable SCR to function could be even higher than the potential NOx reductions achieved by installation of an SCR units at the BRS/EV facility.

In addition to emission increases associated with installation of natural gas fired burners needed for EAF dedusting exhaust gas heating, the ammonia slip associated with SCR installation would cause the release of ammonia emissions (in the form of particulate matter) from each EAF, which are typically not associated with dedusting exhaust gases. The term slip implies that not all of the ammonia used in the SCR system chemically reacts to reduce the presence of NOx in the dedusting exhaust air. EPA's own estimates suggest that SCR can be associated with 2 to 10 ppm ammonia slip, and even a well-functioning SCR would have ammonia slip of 2 to 5 ppm, with ammonia slip increasing as catalyst activity decreases, as it might be expected to occur given the range of feasibility issues entailed in installation on an EAF, including the high temperature variability and airflow variability, and poisoning/fouling/plugging issues.[249]

Using an estimate of 5 ppm ammonia slip due to the factors outlined above, a general estimate of the quantity of ammonia slip can be estimated as follows:

- Appendix A to AP-42 provides the following equation for converting ppm by volume to pounds per cubic foot: M/385.1 X $10(^6)$, where M= Molecular weight of gas. Molecular weight of ammonia is 17.03. Thus 1 ppm ammonia = 17.03/385.1 x $10(^6)$ = <u>4.42 x. $10(^{-8})$ lb ammonia/ft^3</u>
- Thus, 5ppm ammonia slip = 5 x. 4.42 X $10(^{-8})$ lb/ft^3 = 22.1 X $10(^{-8})$ lb/ft^3
- Exhaust gas flow from an EAF is on average approximately 1,300,000 scfm. Actual flow rate does vary based on temperature and other parameters. Multiplying this per minute flowrate by 60 yields a per hour flowrate of 78,000,000 standard ft^3/hour (hr).
- Thus, 22.1 X $10(^{-8})$ lb/ft^3 X 78,000,000 ft^3/hr = 17.238 lb of ammonia slip per hour.

Assuming operation only during the ozone season, 17.238 lbs/hr X 8760 hrs/year (yr) x. 5/12 ozone months/ year X 0.0005 ton/lb = 31 tons of ammonia per ozone season per EAF. Notably, if the SCR was installed downstream of the baghouse, this would be uncontrolled emissions, and would increase PM2.5, since ammonia is recognized to be a significant precursor to secondary particulate matter emissions.[250] In fact, some studies have suggested that reducing ammonia emissions to reduce condensable particulate matter is more cost effective than NOx reductions.[251] On the other hand, if installed upstream of the baghouse, any portion not emitted would contaminate the baghouse dust that is currently recycled/reclaimed by a third party, potentially creating a new and significant hazardous waste stream.

Taken together, the increased NOx emissions from dedusting exhaust air heating and ammonia (i.e., particulate matter) emissions from ammonia slip would negate any environmental value of the SCR given the equivalent or smaller amount of NOx the SCR would be capable of

reducing from each EAF. This demonstrates that SCR installation is not a technically feasible means of decreasing NOx from EAFs by ~50% as would be required to meet the limits in the Proposed Rule and requiring SCR in the face of these realities is arbitrary and capricious.

Finally, it should be noted that unlike SCR retrofits in the powerplant sector where increased air pollution emissions associated with installation of an SCR (both ammonia slip and emissions from heating or cooling fluegas) could be outweighed by even a marginal percentage reduction of NOx given the magnitude of NOx emissions at EGUs (thousands to tens of thousands of tons of NOx per year), in non-EGU contexts like those in the steel industry where EPA proposes to require SCR at units as small at 100 tons per year of NOx, the magnitude of NOx reductions that could be achieved by SCR is simply not significant next to the increased air pollution emissions associated with installation of an SCR. Under these circumstances, SCR is infeasible from an emission reduction perspective because the smaller decreases in NOx associated with SCR at a unit with only a few hundred tons of potential emissions NOx could be significantly offset or even swallowed by electrical consumption of the SCR and its related equipment (indirect emissions) as well as increased emissions from fluegas heating or the increased indirect emissions associated with an increase in energy consumption associated with flue gas cooling equipment, both of which would significant heat/electrical input due to the conditional dynamics required in such short distances.

XVIII. EPA's Cost Analysis Is Arbitrary and Unreasonable as Applied to EAFs, and Especially to Those in Arkansas

A. EPA Fails to Provide Any Cost Estimates Specific to EAFs, Despite Taking Cost Into Account For Other Types of Emission Units

EPA has not provided a cost-analysis specific to EAFs. Instead, EPA provides a generalized estimate $4,345/ton for SCR installation in the broad industry of "Iron and Steel Mills and Ferroalloy Manufacturing." In the first place this generalized aggregation is inappropriate because, as EPA has previously recognized, EAFs are distinct from both ferroalloy production and from other types of steel production such as integrated iron and steel mills.[252] Furthermore, EPA's failure to examine SCR installation on steel mill EAFs is particularly inadequate in light of EPA's

[252] E.g., 57 Fed. Reg. 31,576, 31,582, 31,591 (July 16, 1992) (after determining to "list broad categories of major and area sources rather than very narrowly defined categories," listing Ferroalloy Production, Integrated Iron and Steel Manufacturing, and Electric Arc Furnace Operation as wholly separate source categories under section 112 of the CAA); 39 Fed. Reg. 37,466 (Oct. 21, 1974) (When first proposing CAA Section 111 new source performance standards for EAFs, differentiating EAFs from "old open hearth furnaces"); Background Information for Proposed New Source Performance Standards: Asphalt Concrete Plants, Petroleum Refineries, Storage Vessels, Secondary Lead Smelters and Refineries, Brass or Bronze Ingot Production Plants, Iron and Steel Plants, Sewage Treatment Plants - Volume 1 Main Text at 49, APTD-1352 (June 1973) (As part of docket supporting first NSPS standards for Iron and Steel Plants, eventually published at 39 Fed. Reg. 9308, differentiating between production via "Basic oxygen process; operation of open hearth, blast, and electric furnaces" and stating "The proposed standards would only apply to basic oxygen process furnace"); Background Information for Standards of Performance: Electric Arc Furnaces in the Steel Industry Volume I: Proposed Standards, at 1-4, EPA-450/2-74-017a (1974) (when first setting an NSPS standard for EAFs, differentiating between electric arc furnaces, basic oxygen process, open hearth steel production furnaces, blast furnaces, and coke and sintering plants).

recent declaration that that emission units "must be assessed on an individual basis to determine whether SCR is a feasible control technology based on its site-specific characteristics and the SCR technology available at the time."[253] By failing to conduct any feasibility or cost analyses regarding EAFs, EPA has impermissibly "failed to rely on its own judgment and expertise."[254] If EPA still maintains that units "must be assessed on an individual basis," then it has an obligation to do so. And if EPA no longer stands by that position, it has an obligation to justify its departure from prior policy. EPA has done neither, impermissibly attempting to "depart from prior policy *sub silentio*."[255]

Not only is the cost analysis devoid of any data pertaining to the installation of SCR controls on EAFs, EPA's modeling of cost/ton estimates for SCR did not even include any EAFs at any site in its cost analysis.[256] The Proposed Rule's assertion that EAFs can install SCRs below the cost threshold of $7,500 per ton of NOx is unsupported by the screening assessment on which EPA purports base its assumptions. Furthermore, EPA's own Control Cost Manual in the docket admits that the cost estimates provided <u>are not applicable to non-EGUs</u>, stating that "The procedures to estimate capital costs are not directly applicable to sources other than utility and industrial boilers"[257] and "Due to the limited availability of equipment cost data and installation cost data, the [EPA's Integrated Planning Model EGU specific] equations for SCR capital costs were not reformulated."[258]

Accordingly, as currently composed the Proposed Rule is in clear violation of EPA's obligation to "reflect upon the information contained in the record and grapple with contrary evidence,"[259] and to promulgate internally consistent rules.[260] An agency decision is arbitrary and capricious where, as here "the agency has failed to 'examine the relevant data' or failed to 'articulate a rational explanation for its actions.'"[261]

B. EPA Significantly Underestimates Costs Associated with SCR Installation on an EAF:

Even if one incorrectly assumes that it is feasible to install SCRs on EAFs, there are several reasons why costs will be significantly greater than claimed by EPA, for example:

1. If it were possible to install SCR on EAFs, as noted above, it would require the addition of various systems and equipment to heat and/or cool the exhaust steam, and to reduce pre-baghouse particulate matter loading, and require significant re-engineering of entire air pollution control systems to ensure compatibility and functionality. The cost for this new equipment is not currently accounted for in EPA's cost estimates for SCR installation at EAFs, and as noted in the attached memo from Black and Veatch, these costs are significant.
    a. As noted in Black & Veatch's report, even if one incorrectly assumes that it is technically feasible to install an SCR between the EAF and the baghouse (e.g., catalyst poisoning/plugging/fouling, available space, temperature issues, etc.), the costs installed costs associated with that equipment, whether it is a tempering air system or a spray duct water system are significant, with installed costs (minimally without the benefit of more detailed engineering) of at least $11.7 million and $11.2 million, respectively, for each EAF at the BRS/EV facility (not accounting for ongoing operation and maintenance costs, including increased electricity consumption).
    b. A duct burning system to heat the flue gas after the baghouse likely would cost upwards of $27,800,000 just to install the burners necessary to sufficiently heat the fluegas for SCR to be operable, without even accounting for ongoing operation and maintenance costs, including increased utilization of natural gas).
2. Increased emissions as a result of such heating fluegas in turn would increase SCR costs because the size of the SCR system would need to be increased to reduce these newly introduced emissions. Note also that further NOx controls would be required by third parties to offset indirect NOx emissions associated with indirect emissions associated with electricity demand associated with the operation of the SCR as well as any flue gas cooling system.
3. In order to reduce the large temperature fluctuations throughout the EAF process that might otherwise be destructive to the catalyst, equipment would have to be installed to balance the temperature. Such equipment is not accounted for in EPA's cost estimates for SCR installation at EAFs.
4. In order to reduce inconsistencies in gas flow given the batch nature of the process, additional equipment would have to be installed to level out the velocity of the flue gas and increase it during certain process periods in order for it to flow through the SCR at a reasonable and consistent rate. This new equipment is not accounted for in EPA's cost estimates for SCR installation at EAFs.
5. CEMS are very expensive and EPA specifically says it did not include them in the cost efficiency estimates. More specifically, based on customer-friendly industry quotes obtained by Black & Veatch, installation of a single CEMS system at a single EAF would cost at least $300,000 in capital expenditure. Installation and certification would be at least

an additional $100,000. Annual O&M costs just from a Preventative Maintenance contract would cost at an additional $100,000 per year. These costs do not reflect contingencies that often arise during retrofit CEMs projects. The Proposed Rule would require at least four CEMS units (one for each EAF) at the U.S. Steel BRS and EV facilities in Arkansas.

6. EPA's cost estimates have not been inflation adjusted to 2022 dollars. In addition to inflation, the new normal in the wake of a national pandemic and its havoc on industry has resulted in persistent supply chain issues, which further drives costs. And supply chain issues and associated costs will only be exacerbated by any rule requiring everyone in the industry to purchase and install the same equipment. In light of these factors, it is inappropriate to use older cost estimates without any attempt to adjust anticipated costs to reflect the new normal.

7. Actual studies have been performed to account for the full costs associated with SCR retrofits in the EGU sector suggesting that design, equipment, and installation cost upward of $50 Million in 2006 dollars,[262] or approximately $66 Million in 2021 dollars.[263] Although these cost estimates were for EGUs, they are the only cost estimates available for real world retrofit costs since the technology has never been demonstrated on an EAF. In fact, if possible at all, as noted above, modifications not typically needed at a power plant, such as significant flue gas heating or cooling would be required, so it is reasonable to expect that costs could be higher than these estimates associated with SCR retrofit at an EGU (though EPA has never to our knowledge attempted to estimate costs associated with retrofitting an EAF with SCR, perhaps because it has never been deemed technically feasible as would be consistent with EPA's express statements and determinations prior to the Proposed Rule). At the BRS and EV facilities, the control efficiency required for EAFs in the Proposed Rule would only yield a maximum (potential) NOx reduction of 68.85 ozone season tons from each EAF. The actual NOx reductions achieved would, in reality, be significantly less than this figure since this figure assumes 24/7/365 production at the highest permitted emission rate and throughput from the EAFs which is not a realistic assumption given actual observed NOx emissions and periodic and planned outages for routine maintenance.

8. A study of actual operation and maintenance cost by Electric Power Research Institute found that O&M for an SCR can cost upwards of $2 Million/year.[264] Accordingly, under the extremely conservative assumption of 68.85 ozone season tons per EAF/SCR, this O&M estimate, taken alone, would translates to a cost of $29,049 per ozone season ton

[262] POWER, "Estimating SCR Installation Costs" (Feb. 15, 2006) (discussing EUCG inc. survey of 72 power plants, showing avg cost of 170/Kw for plants in the 300MW range.

[263] Based on CPI Inflation Calculator, available at https://www.bls.gov/data/inflation_calculator.htm (comparing January 2006 dollars to January 2021 dollars).

[264] Electric Power Research Institute, "Operation and Maintenance Costs for Selective Catalytic Reduction Systems" (Technical Update, December 2017).

reduced[265], almost four times EPA's cost effective threshold of $7,500 in the Proposed Rule; and this figure only accounts operation and maintenance, not including the additional significant annualized portion of the initial SCR installation cost.

9. Because of the very different types of ducts required for each EAF, limitations on space available, the designs of these duct systems, the exhaust conditions, temperature delta between them, it is not unreasonable to presume that multiple systems (more than just one tempering or duct burner and SCR unit per EAF unit) may be required in order to achieve predictable repeatable conditions required for the SCR to perform its function without risk of damage to it or other systems.

10. Any retrofit that involves the pollution control system will require operational shutdown for during certain time periods due to system designs and interdependencies, and since the facility cannot legally operate without venting to the pollution controls, and the resulting outage cost from a retrofit could be catastrophic to the iron and steel industry. Notably, steel production is unlike an electric utility with an obligation to provide power 24/7/365 under the worst conditions and therefore has planned accordingly by having a large fleet of electricity units (or contracts with such units) that can be ramped up to replace power during outages. This extended downtown also could result in significant financial implications as electricity and natural gas supply contracts require payment regardless of use. During the months that will likely be needed to ensure equipment and pollution control devices are operational and that all technological retrofits and changes needed have been made, there will simply be no steel production. The Proposed Rule clearly does not consider or contemplate these issues.

C. Cost Annualization Should Account for Fact that Reductions are Not Needed After 2028 in Arkansas.

If EPA does not adjust compliance obligations for Arkansas non-EGU's based on White Bluff's imminent closure, as discussed above, then in the alternative, EPA must at minimum correct the cost analysis to account for the fact that any emission reductions from non-EGUs in Arkansas are only needed for a maximum of two years (2026 and 2027), due to the closure of Entergy's White Bluff coal plant in 2028, since any reductions from non-EGUs beyond that point are unnecessary in order to ensure downwind attainment based on EPA's modeling.[266] Accordingly, the cost of SCR installation at Arkansas non-EGUs should only be annualized over that two year period which is the only period it is legally relevant, rather than annualized over the life of the equipment. Based on the costs estimates derived from EGUs discussed above, this would result in an theoretical, estimated cost per ton calculation for SCR installation at U. S. Steel's BRS and EV facilities of $479,303/ton of NOx reduced per EAF, not even accounting for O&M costs

---

[265] $2,000,000 / 68.85 tons = $29,049.

[266] See above discussion regarding amount of White Bluff emissions versus the amount of reductions EPA modeled from non-EGUs as a result of the Proposed Rule.

or the other technical impediments discussed in this Section .[267] Given the massive cost per ton associated with such a scenario, EPA should instead consider more cost effective short term methods in Arkansas for the 2026 and 2027 ozone seasons and should coordinate with the State of Arkansas in the selection and implementation of such methods.

SPECIFIC COMMENTS PERTAINING TO BY-PRODUCTS COKE MAKING FACILITIES

XIX. EPA Miscategorizes and Fundamentally Misunderstands By-Products Coke Making; and Misapplies Emissions and Technologies to the Process

EPA failed to perform any coke making stakeholder engagement whatsoever in advance of the Proposed Rule. This lack of stakeholder engagement has contributed to EPA's failure to understand the by-product coke making process. The docket associated with the Proposed Rule is extremely light on any technical support for the proposed NOx limits to charging and pushing, and it is apparent that what little information is provided in the docket is not representative of the by-products coke making process. In its rush to regulate, EPA is relying on scant information from heat recovery coke making which is fundamentally different and not representative or applicable to by-products coke making. Furthermore, and most significantly, there are several inconsistencies throughout the Proposed Rule.

U. S. Steel has one remaining coke plant in its footprint – consisting of ten by-products batteries - that is critical to our integrated operations and the domestic iron and steel making industry as a whole. The Clairton coke plant ("Clairton Plant") provides coke to U. S. Steel facilities with blast furnaces as well as third parties – all that are located off-site, and are separate from the Clairton Plant (i.e., the Clairton Plant is not co-located with any blast furnaces.) The facility is the largest coke making facility in North America and is subject to the most stringent air pollution control regulations in the county, according to the Allegheny County Health Department ("ACHD") who has been delegated authority to regulate air pollution sources in Allegheny County from EPA and the Pennsylvania Department of Environmental Protection. After several BART and RACT evaluations over decades, never has EPA, PADEP or ACHD determined that SCR was a suitable or appropriate technology for charging or pushing activities associated with the coke making process. Never before has any of the agencies asserted that charging coal into coke ovens was a significant source of NOx. To the contrary, in AP-42, EPA acknowledges that NOx emissions from charging are not significant.[268] Furthermore, in applying BACT to C Battery in 2012, ACHD determined that SCR was not appropriate.

In the Proposed Rule, EPA upends and departs from years of prior precedent and knowledge with a couple of ambiguous, and even illogical, paragraphs.[269] Yet, this proposed

---

[267] ($66 Million / 2 years) / 68.85 ozone season tons per year = $479,303/ton.

[268] https://www.epa.gov/sites/default/files/2020-11/documents/c12s02_may08.pdf

[269] See page 44 of the Non-EGUs Sectors TSD, where EPA attempts to justify the proposed limits for coke plants with nothing more than: "For coke ovens (charging) and coke ovens (pushing), EPA based the emission limit of 0.15 lb/ton for charging and 0.015 lb/ton for pushing on projected reduction efficiency of 40-50% based on current

technology has not been shown to be available or feasible for these emission sources. While we have many concerns over the Proposed Rule as it would apply to coke batteries, the first overarching comment, as a general matter, is that the Clairton Plant is NOT integrated physically with any iron and steel facilities (e.g., blast furnaces, basic oxygen furnaces, etc.) The facility is a physically separated form and is not part of any "stationary source" consisting of U.S. Steel's integrated iron and steel facilities and operates under the NAICS code 3241, "Petroleum and Coal Products Manufacturing." Thus, grouping coke in the iron and steel sector is inappropriate – especially when Congress and EPA have historically considered the processes unique and separate in other rulemaking efforts. If the coke industry were properly classified in the NAICS code 3241, the charging and pushing would not be included - which is much more logical than what EPA attempts to do in the Proposed Rule.[270]

Second, the Proposed Rule, as it applies to charging at coke plants, is inconsistent and illogical. As noted above, the NAICS code of 3311 is not applicable to stand-alone coke plants. In addition to this inconsistency (where EPA categorizes coke into NAICS code of 3311), in Table I.B-4 of the Proposed Rule, EPA proposes a NOx charging limit of 0.6 lbs/ton of coal charged for coke ovens (charging *and coking*). However, the reference to including "coking" and the 0.6 lbs/ton of coal charged limit is not explained or supported in the Non-EGU Technical Support Document (TSD). Furthermore, it is unclear as to what aspect of the "coking" process EPA intends to regulate, where it intends to regulate, and how it intends to regulate "coking" as noted in this Table – as the docket is void of any supporting information. To add further inconsistencies, in the TSD, EPA attempts to explain the process, but by doing so, it creates additional ambiguities:

> "Often situated in front of a bank of coke ovens, *a separate machine is responsible for opening the coke oven doors, charging and pushing the raw material, and closing the oven again. This machine is often termed a larry car, or charging and pushing machine, among other terms."* [271]

This statement does not accurately describe charging and pushing in a by-products coke oven. While a larry car is used in by-products ovens, it is separate and distinct from pushing and is *done at the top of the oven*. Thus, in a by-products battery, a weighed amount or specific volume of coal is discharged from the bunker into a larry car - a charging vehicle that moves *along the top of the battery*. The larry car is positioned over the empty, hot oven (called "spotting"), the lids on the charging ports are removed, and the coal is discharged from the hoppers of the larry car into the oven. To minimize the escape of gases from the oven during charging, steam aspiration is used

permit emission limits and production-based push/charge cycles. EPA projects minimally 40% NOx reduction efficiency is achievable by use of low-NOx practices, staged pushing and hood configurations, and potential use of add-on NOx control technology at larry cars and pushing/charging machines, including potential use of low-NOx burners, flue gas recirculation, and/or the addition of selective catalytic reduction to mobile hoods and particulate matter control devices."

[270] See, e.g., NESHAP MACT for coke making (Subpart CCCCC) which is separate from NESHAP MACT for integrated iron and steel (Subpart FFFFF)

[271] Page 24 of Non-EGU TSD.

at most plants to draw gases from the space above the charged coal into a collecting main. In addition, charging is not known to emit any appreciable amounts of NOx. It is also not clear on how one would install and operate an SCR on a moveable larry car as EPA seems to propose.

The inconsistencies and ambiguities do not end there. In the TSD, EPA attempts to explain:

> "For coke ovens (charging) and coke ovens (pushing), EPA based the emission limit of 0.15 lb/ton for charging and 0.015 lb/ton for pushing on projected reduction efficiency of 40-50% based on current permit emission limits and production-based push/charge cycles. EPA projects minimally 40% NOx reduction efficiency is achievable by use of low-NOx practices, staged pushing and hood configurations, and potential use of add-on NOx control technology at larry cars and pushing/charging machines, including potential use of low-NOx burners, flue gas recirculation, and/or the addition of selective catalytic reduction to mobile hoods and particulate matter control devices."

Yet, the on-line version of AP-42 refers to a NOx emission factor for charging of 0.03 lb/ton of coal charged, not the 0.3 lb/ton referenced in the preamble of the Proposed Rule, where EPA explains that the proposed NOx limit of 0.15 lb/tons of coal charged is based upon an assumption of "50% reduction staged combustion and/or limited use SCR/SNCR during charging operations from AP-42 0.3 lb/ton emission factor." It is unclear if EPA's reference to 0.3 is in error; or if the AP-42 emission factor is in error. In any case, clarification is needed.

It is significant to note, too, that according to the non-EGU TSD, EPA's proposal assumes a projected reduction efficiency of 40-50% based on current permit emission limits and production-based push/charge cycles; and that EPA projects minimally 40% NOx reduction efficiency is achievable by use of low-NOx practices, staged pushing and hood configurations, and potential use of add-on NOx control technology at larry cars and pushing/charging machines, including potential use of low-NOx burners, flue gas recirculation, and/or the addition of selective catalytic reduction to mobile hoods and particulate matter control devices. While EPA makes these very broad assumptions and conclusions on the expected reductions on one hand, on the other hand, in the non-EGU TSD, EPA acknowledges that, "coke ovens with NOx controls in the United States have not been found." Yet, EPA, for the first time, is proposing sweeping NOx controls across coke plants in the United States under the guise of its authority under the Clean Air Act to address interstate transport of pollutants.

It is important to add, that overall, the NOx emissions from charging and pushing are minimal and any emissions control equipment installed would result in minimal NOx reductions. Most importantly the application of SCR technology is not feasible from a technical perspective and, even if assuming it was, is not economically feasible, particularly in light of EPA's limited legal authority in the Proposed Rule to impose only controls necessary to mitigate significant contribution to nonattainment or interference with maintenance without any overcontrol. It also would substantially increase other pollutants. Work produced by Trinity Consultants shows:

> "Trinity calculated cost effectiveness for potential application of SCR at the Clairton C Battery coke pushing, after the baghouse. The minimum annual cost effectiveness would

be $271,472/ton (2021$), with 72 tons of NO_X formed from combustion of natural gas to reheat the exhaust gas steam compared to approximately 92 tons from the unit itself, as well as approximately 87,000 tpy of CO_2."

These numbers clearly show how the application of SCR to coke ovens is not a cost-effective approach and should not be required. This is yet another example of the Proposed Rule not accurately reflecting the costs of implementation and overstating the potential NOx reductions.

In addition, it is unclear as to what coke plants would even be subject to the rule because the two types of emission units at coke plants that would be subject to the rule are (1) coke ovens (charging) and (2) coke oven push cars and pushing-charging machines (pushing). Based upon the description of the "emission unit" in the proposed rule and the applicability, it would appear that no coke oven (or coke battery, for that matter) would be subject to the proposed limits because the PTE at these two sources are well below 100 tons.

U. S. Steel also respectfully notes that it is unclear on how EPA's modeling incorporates NOx reductions that would be achieved through these NOx emission limits. For example:

- In the pre-FIP model, what inputs did EPA consider from coke plants?
- How were these relatively insignificant sources of NOx emissions shown to contribute or interfere with ozone nonattainment in downwind receptors?
- How did EPA show that the proposed controls for these units would result in any measurable improvement in ozone concentrations monitored at n downwind nonattainment receptors?

For the reasons explained above, U. S. Steel respectfully contends the Proposed Rule is fatally flawed because the emission estimates and projected reductions are not legally or technically supported by anything in the docket – and we further contend that this is because the Proposed Rule as it applies to coke plants is indeed unsupportable by fact or law.

SPECIFIC COMMENTS PERTAINING TO INTEGRATED STEEL MAKING OPERATIONS

XX. Summary of Overarching Concerns

As explained in more detail throughout and below, we have the following overarching concerns with the Proposed Rule as it relates to U.S. Steel's integrated steelmaking operations:

1. Due to numerous fatal flaws and fundamental errors in the proposed rule, EPA must re-evaluate ozone impacts from the iron and steel industry to determine if they do indeed interfere with ozone attainment in downwind states; and only if it is shown that such interference does occur and only after State are afforded ample opportunity to correct any SIP deficiencies, issue a revised proposal with requisite supporting information for the Good Neighbor FIP for the steel industry.

2. The comment period was entirely insufficient and unjustified as EPA supporting documentation is very scant for many emissions units and their respective proposed limits.

3. The docket is missing numerous critical files to evaluate EPA's proposal. Providing the critical files for stakeholder review and comment is needed for stakeholders to provide comments.

4. There was insufficient time to conduct a robust review of the air quality modeling and to conduct an independent modeling analysis, especially in light of the fact that it took several days after the public comment period for EPA to provide stakeholders with the requested modeling files – inappropriately abbreviating an already entirely too short comment period. The files should have been public available on Day One of the comment period.

5. EPA inappropriately uses a 1% (0.7 ppb) threshold rather than the 1 ppb threshold that EPA previously provided States as an appropriate threshold to determine potential NAAQS interference. In short, EPA provided guidance to States (and the regulated community and other stakeholders) and then rejected SIPs that relied on that guidance, and, instead, replaced it with a lower triggering threshold to supplant state's engagement and primacy in the implementation of the Clean Air Act requirements as Congressed intended.

6. The docket does not have the requisite information to support a finding that the facilities in the EPA's iron and steel sector significantly interfere with ozone attainment in downwind states.

7. EPA's stated basis for cost-effectiveness is RACT, but EPA applied beyond-RACT and beyond-BACT/LAER levels of control to establish emission limits for the steel industry, without any justification of its deviation from RACT. It is illogical on how EPA is now attempting to impose limits that are akin to RACT limits that are more stringent than BACT and LAER limits. A review of the RBLC does not support EPA's proposed limits and technologies.

8. EPA's reliance upon the Menu of Control Measures (MCM) and the Control Strategies Tool (CoST) to identify cost-effective emissions control options for the steel industry is fundamentally flawed, as the underlying studies that EPA used to identify cost-effectiveness did not include numerous U. S. Steel source types where EPA proposes controls in the rule, and EPA chose cost-effectiveness values at the bottom of the study cost ranges despite statements in the underlying studies regarding the screening level approach and likely under-estimating costs.

9. Underlying studies only estimated NOX control costs for reheat and annealing furnaces

10. EPA improperly assigned cost data based on reheat and annealing furnaces to all steel process units in the proposed rule

11. There is no basis in EPA's inclusion of numerous other steel unit types for regulation based on CoST and MCM, when CoST and MCM only have input data for annealing and reheat furnaces

12. EPA's cost estimates inaccurately assume year-round operation of control devices resulting in underestimating cost-effectiveness because the regulation can only apply to the five month ozone season, meaning EPA's cost estimates were only 5/12 or 42% of the real cost effectiveness – This critical error significantly underestimates the cost effectiveness of the proposed controls (even if such controls were found to be technologically feasible)

13. Nothing in the docket supports a finding that any of the proposed reductions (individually or collectively) would have any measurable impacts in downwind states.

14. The lack of a trading option puts non-EGUs at a significant disadvantage when compared to EGUs, is illogical and makes EPA's errors in setting unit-specific emission limits even more critical to the extent many errors result in fatally flawed rule. In addition, EPA has not proposed a case-by-case option for emission units that would be subject to the regulation, whereas almost every prior RACT rule has recognized that emissions and technologies are not fungible and such determination are many times best determined on a case-by-case basis when the general technology and/or limit is shown to be inappropriate or infeasible.

XXI. Due to the Lack of Stakeholder Engagement EPA Fails to Understand the Integrated Steel Making Process.

The Bureau of Industry and Security and Department of Commerce have determined that domestic steelmaking is necessary for our nation's security production requirements and without domestic steel production we run the risk of not being able to adequately respond to a national emergency. In addition, the U.S. Department of Homeland Security has designated steelmakers like U. S. Steel, to be a vital component of our nation's critical manufacturing sector, which is necessary for the economic prosperity, security, and continuity of the United States. The COVID-19 pandemic and the Russian-Ukrainian conflict have highlighted the importance of having robust domestic manufacturing capabilities to supply important products that are essential to national, economic and health security. Therefore, it is imperative that any rulemakings that have the potential to significantly impact the steel industry are accurate and well-grounded in the law and technology. Unfortunately, EPA's Proposed Rule short of these critical criteria.

U. S. Steel has been a critical partner with Federal, State and local governments for over 120 years. Today U. S. Steel employs our "Best For All" strategy where we are diversifying our capabilities and technology through a balance of Integrated Iron and Steel Facilities with scrap to steel facilities using Electric Arc Furnace (EAF) technology. This strategy is critical for U. S. Steel to work towards more sustainable steel production.

In developing the Proposed Rule, EPA did not reach out to U. S. Steel or, to our knowledge, any steel sector stakeholders. This lack of outreach has led to EPA proposing a rule that is illogical and infeasible. In order to truly have a Proposed Rule with positive impacts would require EPA to have a least a minimal understanding of the non-EGU sectors they seek to regulate.

For all of the non-EGU sectors targeted in the Proposed Rule, EPA generically grouped all facilities by the assigned NAICS codes without any attention to the details of the actual facilities, and emission units to be regulated. As discussed within our comments, EPA did not develop emission limits in the Proposed Rule for the emission units to be regulated, but instead attempted to apply a one sizes fits all approach to NAICS code groups like iron and steel facilities. For example, EPA makes assumptions that all reheat furnaces have similar feasibility for emission control technology and the same emission rates even though there are vast differences among the technology and type of reheat furnaces across the iron and steel industry with different emission profiles and emissions

EPA has not clearly explained its screening process in assessing the iron and steel industry. More details are needed for the industry to be able to comment accordingly. For example, in the Proposed Rule, EPA claims that sources with *actual emissions greater than 100 TPY* were assessed, *except well-controlled sources*. However, after reviewing the purported supporting documentation from the docket, it is not clear on what criteria U.S. EPA used to determine if a source was *well-controlled*, and what sources it considered were indeed well-controlled. In addition, EPA states that the rule would apply to any *emission unit* that directly emits or has the *potential to emit* 100 tons per year or more of NOx (and to each BOF Shop containing two or more such units that collectively emit or have the potential to emit 100 tons or more per year or more of NOx. There is a significant difference between actual emissions of over 100 tons and PTE of over 100 tons. In addition, it also appears that a number of emissions units less than 100 TPY actual emissions would inexplicably be covered in the iron and steel category of the Proposed Rule. It is not clear on how or why EPA would include many of the emission units in this category to be subject to FIP limits.

In addition, it is unclear on how BOP Shops are to aggregate emission units; and why and how EPA believes SCR on many of the smaller emission units within a BOP Shop would be appropriate and feasible. For example, BOP Shops generally have a few or several ladle/tundish preheaters. These preheaters are small sources of NOx and NOx controls on these units – even if assumed to be technologically feasible (which it is not)– would not be economically feasible.

XXII. EPA Failed to Determine Technological Feasibility Related to Integrated Iron and Steel Process.

As explained herein when applying RACT, EPA must demonstrate that the proposed limits are both technically and economically feasible on a facility and unit specific basis. And even stricter standards like BACT still require an analysis of technical and economic feasibility. And in any case, EPA has an independent "duty to examine [and justify] key assumptions as part of its affirmative 'burden of promulgating and explaining a non-arbitrary, non-capricious rule. . . .'"[272]

[272] *Appalachian Power Co. v. EPA*, 328 U.S. App. D.C. 379, 135 F.3d 791, 818 (1998).

and EPA may not "promulgate rules on the basis of inadequate data, or on data that, to a critical degree, is known only to the agency."[273] And thus EPA's assumptions regarding feasibility in the Proposed Rule must be adequately justified. EPA has failed to meet its legal burden as it related to the emission limits in the Proposed Rule related to emission units at integrated iron and steel operations.

A. General Issues with the Application of the Proposed Rule to Integrated Iron and Steel Operations.

The Proposed Rule makes erroneous assumption and contains errors that result in fatal issues with its application to the iron and steel industry. The application of the Proposed Rule will require significant operational changes, excessive costs and, in many cases, minimal NOx reductions and actually increases other air pollutants. The SCR technology in the Proposed Rule is not feasible for the sources/emission units in the iron and steel sector that EPA proposes to regulate. Notwithstanding the fact that EPA has not shown if or how iron and steel facilities are contributing to or interfering with ozone attainment in downwind states, even it did, due to the incompatibility of post combustion controls such as SCR/SNCR with many of emission units at integrated iron and steel facilities, EPA's emission limits in the Proposed Rule are not feasible and are therefore unlawful.

EPA has failed to provide support in the Proposed Rule or accompanying technical documents to show that these required emission reductions are actually achievable or, even if they were, how they would result in any measurable improved ozone air quality in downwind states. In many instances equipment and fuels within the steelmaking industry are already low NOx so reductions are not likely to be achieved; and if any further reductions were technologically feasible, they would be cost prohibited as explained in the Trinity Report and the Barr Report. For instance, the Proposed Rule EPA proposes "[f]or a vacuum degasser, NOX is not generated in the process and so NOX control cannot be applied there despite EPA's proposed control. And for an LMF, EPA proposes low NOX burners as a control technology, but there are no burners in an LMF." Again, in its rush to regulate, EPA has proposed a fatally flawed rule that, if promulgated, would lead to illogical, infeasible results at great costs without a required showing of favorable impacts in the downwind states. That being said, U.S. Steel is committed to working with EPA on sound, proven sensible solutions that are technologically and economically feasible and result in measurable ozone improvements in downwind states if, and only if, EPA first demonstrates and shows that the iron and steel industry interferes with ozone attainment in downwind states, which it has not done so in the proposed rule or its purported supporting documents.

Some of the emission units and US Steel's integrated steel facilities to which EPA would have the SCR emission control applied would require significant preconditioning and heating of the exhaust gas to make it amenable to SCR. The conditioning and heating of exhaust gas prior to being able to utilize a SCR would not only be difficult to design and operate but would also require increased use of natural gas and have other impacts and costs not considered by EPA. The

[273] *Portland Cement Ass'n v. Ruckelshaus*, 158 U.S. App. D.C. 308, 486 F.2d 375, 391-93 (1973).

increased combustion of natural gas that would be required to condition the exhaust gas for a SCR would increase various emissions such as CO2, PM, SO2 and even NOx. The increase in NOx clearly goes against the purpose of the Proposed Rule. Nor did EPA consider the design and infrastructure that would be needed for the conditioning and preheating or the environmental impacts associated with the increases in emissions associated with conditioning and preheating. These issues were overlooked or not recognized by EPA during the development of the Proposed Rule.

EPA also failed to fully and accurately develop the costs that would be incurred by the iron and steel industry. The EPA claims that the SCR technology and the limits set in the Proposed Rule would be cost effective but to arrive at that calculation the costs were estimated if technology ran year-round and not just during ozone season (for. Trinity Consultants provides the following information related to their review of the costs associated:

> "For instance, EPA estimates that selection of SCR in the Iron and Steel Mills and Ferroalloy Manufacturing Industry may be associated with 948 ozone season NOx reductions, at an annual cost of $9,886,092. If EPA had calculated the cost per ozone season ton of NOx reduced, this would result in an estimate of $10,428 per ton of NOx reduced, which is well above the cost threshold of $7,500 stated by EPA). But EPA instead, without justification, lists the average cost per ton as $4,345, which would only be the case if the ozone season tons were extrapolated to assume continuous annual reductions."

In the Proposed Rule, EPA started from a limit that was the lowest emission rates identified in any prior RACT or BACT analysis and inexplicable applied additional controls that would lead to arbitrary and unsustainable additional reductions. These reductions were based on control technologies never before applied to these emission units and only based on incorrect generic assumptions. EPA uses similar approaches for the proposed emission limits for all steel units in proposing emission limits far below those determined as either BACT or RACT in unit-specific analyses. This all further supports that EPA used a flawed methodology in the development of the Proposed Rule. We further note that it is illogical and inappropriate for EPA to now require an unjustified, unproven (and infeasible) limit that is significantly lower than BACT or LAER.

B. Application of the Proposed Rule to Specific Integrated Iron and Steel Operations.

The application of the Proposed Rule to various equipment within an integrated iron and steel facility causes many similar issues. This section will address what some of the concerns are with each part of the operations. The issues with the application to the integrated facility are discussed throughout these comments. The emission units discussed below are also discussed in more detail in the Trinity Report found at Exhibit D.

1. Blast Furnace Operations.

The blast furnace converts iron oxide into molten iron for subsequent refining in the BOPF shop to produce steel. A typical burden (feed) may consist of iron ore, pellets, sinter, limestone, coke, mill scale, BOPF slag, and other iron bearing materials. The burden material is charged into the top of the furnace and slowly descends through the furnace. The coke provides the thermal energy required for the process and provides carbon to reduce the iron oxide and to remove oxygen in the form of CO. To U. S. Steel's knowledge, SCRs are not installed on any blast furnaces domestically or internationally, and in the TSD and docket materials, EPA does not cite to any successful application of SCR at any blast furnace ("BF"). This is because SCRs are not technologically feasible as a NOx control for blast furnaces; nor are they cost-effective. U. S. Steel conducted a BART analysis of the BF at Gary Works in 2020 and a RACT analysis at the Edgar Thompson facility in 2014 both of those evaluations indicated the Proposed Rule is not feasible. These are both discussed further in the Trinity comments found in Exhibit D.

BFs use blast furnace gas, coke oven gas, or other heat sources to generate the heat necessary to metal the iron. The use of regenerative heat capitalized on the blast furnace gas ("BFG"). BRG is a low NOx gas and already uses a best practices approach and minimizes the impact on air emission. Any excess BFG is flared to minimize air impacts. EPA seems to fail to realize that the SCR technology is not compatible with a BFG gas flare. If BFG was not used to heat the BF then it would require increased use of natural gas, which would have a negative impact on air emissions.

The application of the Proposed Rule to BFs and the limits established were incorrectly achieved. As stated in Exhibit D, prepared by Trinity Consultants:

> "For blast furnaces, EPA started with an Ohio RACT limitation and then assumed a 50% reduction (from that RACT limitation) based on application of a control technology never before applied to this source type. EPA uses similar approaches for the proposed emission limits for all steel units in proposing emission limits far below those determined as either BACT or RACT in unit-specific analyses. EPA appears to base its approach on an incorrect interpretation of the data in MCM and CoST and does not include any fact-based finding that these technologies are applicable to the steel emission units as part of this proposal."

Emission limits should be set following the application of appropriate regulatory requirements, accurate information, with appropriate control technologies. It appears that none of this was done with the development of the emission limits for the Proposed Rule.

2. Basic Oxygen Process.

Basic Oxygen Process (BOP) is treated differently than all other non-EGU sources. In the other various non-EGU sources there is potential to emit of 100 tpy of NOx as individual emission units to be included in the Proposed Rule. However, BOP operations are required to combine all emission units in determining whether the emission limits in the Proposed rule apply to the emission units at the BOP operations. This combining of emission units results in the application of SCR requirements to potentially very small emission units that do not have an associated stack. Requiring SCR emission controls on units that emit very few tons of NOx per year is overly burdensome, costly and will have no impact on downwind states. The result is illogical.

The BOP is not conducive to the application of the Proposed Rule's SCR technology to decrease NOx emissions. BOPs typically operate with a wet scrubber exhaust system which produces a gas too cool to go into a SCR/SNCR without significant conditioning and heating. Even assuming there is sufficient space, the BOP exhaust system would have to be a completely new design likely to include larger fans and increased duct work. The gas would also have to be heated to temperatures compatible with the SCR resulting in significant, independent NOx emissions. Both of these equipment additions would lead to increased natural gas and electricity usage.

EPA did not consider the costs for redesign of the BOP systems (nor should it as such redesign goes beyond RACT), modification of equipment and process to attempt to work with the SCR requirement, additional equipment needed, additional natural gas, or additional electricity costs. In the EPA's limited understanding of the iron and steel process they also failed to realize that imposing the SCR technology will also lead to emission increases associated with the increased usage of natural gas and electricity. Nothing in the rulemaking docket indicates that EPA considered these costs and impacts; and how the (incorrectly) assumed reductions benefit downwind states.

It is significant to note that EPA has not shown how SCR has been applied on any BOP Shop; and that the anticipated reductions are indeed achievable – technologically and economically. In the TSD, EPA states that it based the emission limit of 0.07 lb/ton of steel on performance testing data from basic oxygen furnaces without NOx reduction controls at integrated iron and steel mills in the United States. EPA then projected what it refers to as a minimal 50% NOx reduction efficiency that EPA, without any support whatsoever, is achievable by use of low-NOx technology, including potential use of FGR and selective catalytic reduction." EPA's rather simplistic approach is that because most BOF vessels and associated BOF Shops in the United States are already equipped with capture technology and existing particulate matter control devices, the NOx reduction technology could simply be integrated to the existing controls. This over-simplification is not supported by fact or law. EPA has not shown that SCR has been successfully applied to BOP Shops. The dynamic conditions in the exhaust gases, including dramatic swings in flow and temperature (e.g., oxygen blow vs. charging or tapping) make SCR inappropriate – and this is supported by the fact that EPA and states/air agencies have never applied SCR to the basic oxygen furnace process shops for any RACT, BACT or LAER determination. However, with the broad stroke in one simple paragraph, EPA, without any support, upends decades of prior determinations, and now inexplicably claims SCR is somehow feasible and appropriate. The TSD is scant on any support – but instead EPA relies on false assumptions.

3. Ladle Metallurgy Furnace.

Ladle metallurgical furnaces (LMF) are used in the steel industry to increase the liquid metal temperature for casting and to produce steel grades by adding alloys. The LMF process is a batch process and since there is no combustion source (except for de minimis amounts associated with the consumption of electrodes by oxidation with oxygen in capture air) there is minimal NOx emissions. In sum, applying SCR at an LMF is inappropriate and illogical. In addition, the application of SCR is not technically feasible, in part due to the batch process of the LMF. Even if one were able to determine how to implement the SCR on a LMF, it would not be cost-effective as it would require an entire redesign of the system and process with de minimis reductions in NOx. Furthermore, because EPA includes LMF as part of the BOP Shop, there is no de minimis threshold for the applicability of the FIP to LMFs (assuming that the BOP Shop's PTE (from all units within the shop) is 100 tons or more. This is illogical – so illogical that the cost effectiveness would be approach $2 million per ton of NOx removed – several orders of magnitude of EPA's purported cost threshold of $7,500/ton. Furthermore, EPA has not shown how LMFs (individually or aggregately with other emission units) interfere with ozone attainment in downwind states; nor has EPA shown how the emission limits for LMFs would lead to any measurable benefits in ozone in downwind states.

4. Degassers.

EPA appears to have a fundamental misunderstanding of vacuum degassing and NOx emissions (de minimis) associated with the process. Vacuum degassers (VDGs) are used in the steel industry to remove certain gases from the molten steel prior to casting. This helps to produce the desired properties of the finished steel. Degassers can remove hydrogen (H_2), oxygen (O_2), and nitrogen (N_2) that are dissolved in the liquid metal. They are also used to reduce the carbon content of the steel prior to casting to produce an ultra-low carbon product.

While not clear from Proposed Rule, it would appear that EPA would intend to include vacuum degassing in the BOF Shop, and therefore, not subject to the triggering 100 ton PTE threshold, and, instead, would inexplicably be included and subject to the proposed limits even if no appreciable reduction would result. The process of the degasser itself does not generate NOx – and therefore its inclusion in the proposed rule is perplexing. The only NOx associated with vacuum degassing is NOx generated by the flare when CO abatement and is a function of adiabatic flame temperature which is related to excess air, fuel usage and flare design. EPA's has scant support for its inclusion of vacuum degassing and the proposed limit of 0.03 lb/mmbtu on existing permit limits of 0.05 lb/mmbtu. (EPA's entire technical support discussion in the non-EGU TSD for the limit is provided below:

> "For vacuum degassers utilized in secondary steelmaking, EPA based the limit of 0.03 lb/mmBtu on existing permit limits of 0.05 lb/mmBtu. EPA projects minimally 40% NOx reduction efficiency is achievable by use of low-NOx technology, including use of selective catalytic reduction."

EPA does not provide any further explanation – and a review of the RBLC does not support EPA's ambiguous and vague conclusions.

Installing emission control technology on VDGs is not feasible. VDGs are a batch process and has variables in the exhaust gas. Again, due to the de minimis amounts of NOx peripherally associated with vacuum degasser flares and the low potential reduction of NOx from installation of SCR technology (even if it were feasible, which it is not) results in a technologically infeasible limit that is not cost-effective. VDGs also are very low in NOx emissions and do not meet the 100 ton per year threshold in the Proposed Rule. However, the VGDs are inexplicably pulled into the aggregated numbers of the BOP or BOF emissions

5. Ladle/Tundish Preheaters.

Ladle or Tundish preheaters are small natural gas burners that direct fire ladles to keep them warm, dry or preheat them – as an ancillary process and to better preserve refractory. The preheaters are used to dry out ladles and there is no vent or combustion exhaust gas capture. In this case SCR technology is not feasible as there is nothing to add the SCR to at the end of the exhaust. EPA failed to understand the use of these preheaters and did not make any determination as the feasibility of putting SCR on the ladle or tundish preheaters. If the Proposed Rule is finalized there would be significant costs in trying to absolutely redesign these preheaters to accommodate the possibility of SCR.

Ladle preheaters are such a small potential source of NOx that there will be no impact from this change on downwind states. Most states already consider this to be an insignificant activity for air emissions and consider it fugitive emissions.

The gas burners on the preheaters are very small with heat inputs of typically 5-15 MMBtu/hr. In addition, the preheaters are needed to be mobile so that they can be use don ladles throughout the shop. The very small heating value, coupled with the de minimis NOx emissions from ladle preheating, and the inconsistent and mobile operation makes SCR technologically infeasible. And even if SCR were technologically feasible, which it is not, it would not be economically feasible, as even if the emissions from the units were able to be captured in a hood and treated, the cost estimate of nearly $50,000/ton of NOx removed, not including any costs associated with hooding and other infrastructure needed to accommodate the technology. Simply, the proposed limit based upon application of SCR is perplexing.

The ladle preheaters are very low in emissions and do not meet the 100 ton per year threshold in the Proposed Rule. However, the preheaters are inexplicably pulled into the aggregated numbers of the BOP or BOF emissions. Any potential reduction from ladle or tundish preheaters would be minimal and would not be cost-effective. Furthermore, EPA has not shown how the insignificant NOx emissions from ladle/tundish preheaters interfere with ozone attainment in downwind states; or how downwind states would have any measurable benefit from the proposed limits. Again, there appears to be a fundamental misunderstanding of the industry and the limitations of the proposed SCR technology to these sources.

6. Hot Strip Mill Operations/Reheat Furnaces.

Hot Strip Mills are specifically designed operations, and any addition of equipment or technology requires significant planning, engineering, time, and money. EPA's failure to understand the complicated operations at a hot strip mill has led to the Proposed Rule significantly underestimating the difficulty that would be involved in retrofitting the prescribed emissions control equipment in the Proposed Rule. The cost and ability to retrofit equipment within a hot strip mill is going to be extremely difficult and require significant modification to operations. A retrofit of this nature will also cause significant downtime and associated loss of revenue. The proposed SCR technology if it is even capable of being installed will require extensive modification to accommodate the changes.

The U. S. Steel Gary Works facility as well as other facilities have completed a RACT analysis for hot strip mill operations related to Regional Haze. Operations at these facilities have already been modified to meet the RACT requirements. The Proposed Rule attempts to regulate beyond the requirements already in place, through what can only be characterized as a "beyond-LAER" emission limit. LEAR. All of the changes (for all integrated iron and steel operations) in the Proposed Rule will have a minimal impact on attainment in downwind states. Continuing to push for unproven and very costly technology to be applied with little to no appreciable improvement is not the purpose of this section of the CAA.

Reheat furnaces are used to reheat slabs of steel to work and shape the steel into another product. The reheat furnaces use uniform heat and hold the desired temperature for a set time. The design and operation of reheat furnaces makes SCR technology infeasible.

The U. S. Steel Irvin Works evaluated RACT for a reheat furnace in 2014. Trinity Provides an overview in Exhibit D. However as expected "That analysis found that the cost of adding low NO_X burners would be $14,100/ton, which is not cost effective." The U. S. Steel Gary Works facility then conducted a BART analysis for reheat furnaces in 2020. The BART analysis found that the cost of adding low NO_X burners would be $14,100/ton, which is not cost effective under the purported cost threshold of $7,500 that EPA arbitrarily set forth iron and steel units in the Proposed Rule. Due to the heat needed these burners would likely increase the energy use as well. Creating another expense and likely increasing air emissions.

Again, EPA fails to understand the iron and steel industry and does not show that the Proposed Rule meets its purpose to improve air emissions related to NOx.

7. Annealing Furnaces.

Annealing furnaces go through a series of heating and cooling process allowing hard metals to have various ductility and strength. Annealing furnaces are designed to operate in a batch or continuous function. Continuous Annealing furnaces are the only steelmaking equipment that has been shown to be feasible with the SCR technology. However, SCR is not feasible on batch annealing furnaces.

While the SCR technology may be technologically feasible for continuous annealing furnaces it is not cost effective. Trinity Consultants performed a "control cost effectiveness analysis on the Irvin open coil annealing furnace, which showed that the SCR cost effectiveness would be at best $25,630 (2021$). This is well beyond the EPA stated $7,500.

EPA also did not use the proper methodology to set emission limits for the annealing furnaces. There is additional technical information in the document prepared by Trinity Consultants which states "for annealing furnaces, EPA started with recent BACT determinations, and then applied an additional 40% reduction without any demonstration of achievability of the proposed limit." These numbers are not based upon proper determinations and EPA did not provide support for the additional 40% reduction found in the Proposed Rule.

8. Boilers

Boilers used at integrated iron and steel facilities vary greatly as will the NOx emission rates. These boilers will also have a variety of fuel sources and operating parameters. Each boiler would have to be evaluated as to the potential to reduce NOx emissions, the technical feasibility of SCR and the cost effectiveness.

U. S. Steel conducted a BART analysis on the Clairton facility boilers in 2022. That analysis showed the SCR annual cost effectiveness was at minimum $20,873/ton on Boiler 2, and more expensive on others. Additional review has been done at other U. S. Steel facilities and that information is provided in the Trinity Report in Exhibit D.

Some of the boilers already combust BFG which is low NOx and considered a best practice. This is significantly better from an environmental perspective than an alternative like natural gas that would displace the BFG and increase air emissions. Any modification of boilers would require significant modification to attempt to accommodate SCR. This would not only be costly but would likely produce negative air impacts, especially if boilers were switched to natural gas.

Boilers are yet another area where EPA need to evaluate in more detail, likely through a separate rulemaking or individual RACT determinations, in order to justify the emission limits, it purports to apply "wholesale" to boilers in the Proposed Rule.

SPECIFIC COMMENTS PERTAINING TO MINNESOTA MINING OPERATIONS

XXIII. Minnesota Should Not be Regulated in the Proposed Rule.

Minnesota is not having a significant impact on downwind air quality. Minnesota was identified as a non-significant contributor (below 0.7 parts per billion) to any ozone monitors in the 2018 modeling performed by both EPA and LADCO. Minnesota's original submittal should have been approved based on contribution information available from both EPA and LADCO at that time.

While EPA now maintains that, with new modeling, it has found contributions in excess of 0.71 ppb at two monitors, EPA's position that this alone is sufficient to subject Minnesota to regulation is based on an overly-conservative assumption that a 1% threshold is sufficient to justify regulation of downwind ozone impacts.

Breaking out the sources of the receptor impacts EPA modeled shows that the regulated emissions from Minnesota are having less than a 0.3 ppb impact on down-wind monitors.

2026 MN-Specific Scenario	Total Ozone (ppb)	State Impacts (ppb)	Non-EGU (ppb)	EGU (ppb)
Illinois (001) Results (ppb)	72.5	0.91	0.19	0.04

Illinois (076) Results (ppb)	71.3	0.75	0.18	0.03

In other words, eliminating all non-EGU and EGU emissions from Minnesota would not affect Illinois' attainment status.

If the sources being evaluated for controls are not providing a reduction that would have any appreciable impact on attainment or maintenance of the NAAQS, then EPA cannot support regulating those emissions as "amounts which will—(I) contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any such national primary or secondary ambient air quality standard." 42 U.S.C. § 7410(a)(2)(D)(i)(I); *see also EPA v. EME Homer City Generation, LP*, 134 S. Ct. 1584 (2014) ("EPA cannot require a State to reduce its output of pollution by more than is necessary to achieve attainment in every downwind State or at odds with the one-percent threshold the Agency has set. If EPA requires an up-wind State to reduce emissions by more than the amount necessary to achieve attainment in every downwind State to which it is linked, the Agency will have overstepped its authority, under the Good Neighbor Provision, to eliminate those "amounts [that] contribute ... to nonattainment.").

Simplified assumptions are sometimes appropriate and necessary in a complex modeling analysis such as a national photochemical ozone evaluation. However, when the results are used to justify costly controls and monitoring on a significant number of industrial operations in the state, further culpability refinements need to be assessed. Arbitrarily requiring controls across multiple non-EGU facilities in a state contributing more than 0.71 ppb to a modeled ozone value greater than 70 ppb demands an extra step confirming that the specific non-EGU sources EPA seeks to regulate are in fact significant contributors from each state.[274] Again, looking at the impacts modeled for the State of Minnesota, the maximum modeled impact is less than 1 ppb.

MN	Keetac, Minntac	Cook (1), IL: 73.4 Cook (76), IL: 72.1	Cook (1), IL: 0.97 Cook (76), IL: 0.79	Cook (1), IL: 72.5 Cook (76), IL: 71.3	Cook (1), IL: 0.91 Cook (76), IL: 0.75

As discussed in the above Section VI. G titled "Improper Significance Screening Threshold," no impact below 1 ppb can be considered significant, due to EPA's 2018 guidance finding that a 1 ppb threshold is generally comparable to a 1% threshold for the 2015 ozone NAAQS in terms of the contributions it would cover, 1 ppb being the lowest significant digit used for reporting ozone monitoring data under the NAAQS, and EPA previously determining based on statistical analysis underlying the Ozone SIL that no contribution below 1 ppb can have a

[274] In fact, as discussed previously, there is no statutory justification for EPA to group unrelated industries together as a lump title of "non-EGU" sources for purposes of evaluating the significance of impacts, and it is arbitrary to lump all such industries together when EPA provides industry specific consideration to the EGU industry. EPA must evaluate the significance of the particular sources is seeks to subject to the rule if it wishes to impose facility or unit specific emission controls. If on the other hand EPA wishes to create an emissions trading regime similar to that currently in place for EGUs, EPA must at minimum demonstrate that any industries included in such trading regimes are significant contributors to each specific state's linked receptors.

significant impact on a downwind receptor. Based on this limited impact at even the maximum modeled influence on receptors, EPA's argument that Minnesota emissions need to be controlled for future ozone NAAQS demonstration based on a maximum contribution of between 0.75 and 0.97 ppb is not justifiable.

EPA's decision to regulate Minnesota based on a maximum modeled contribution of 0.97 ppb rather than EPA's guidance threshold of 1 ppb also is particularly troubling because the model EPA is using lacks the consistency and accuracy needed to make such fine-grained distinctions. Rather, based on EPA's own assessment in the modeling TSD, "the regional mean bias of the model is +/- 5 ppb and the mean error is between 6 and 7 ppb on average for all days during the period May through September in each region."[275]

	Model/Obs. (ppb)	Mean Bias (ppb)	Mean Error (ppb)	Standard Deviation (ppb)
Cook County, IL (001)	60.75/68.97	-8.22	11.13	8.16
Cook County, IL (076)	57.87/67.77	-9.90	11.85	8.65

These numbers challenge the assumption in the Proposed Rule that emissions from Minnesota are "significant." It is simply insupportable to assert that unprecedented and costly emission reductions are needed to achieve an impact on down-wind monitors that is less than the error in EPA's model.

XXIV. Taconite Should Not be Regulated in the Proposed Rule.

Taconite is not part of the Iron and Steel and Ferroalloy Manufacturing Industry Group. EPA's modeling analysis of contributions from non-EGU emission units was conducted on an industry-group basis, based on 4-digit NAICS codes.[276]

EPA created two "tiers" of industry groups. *Id.* The first tier includes four industries that EPA proposes it "should focus the assessment of NOx reduction potential and cost primarily on": pipeline transportation of natural gas; cement and concrete product manufacturing; iron and steel mills and ferroalloy manufacturing; and glass and glass product manufacturing. *Id.* The preamble to the Proposed Rule appears to include "Taconite production kilns" as a source in the Iron and Steel and Ferroalloys Manufacturing Industry Group.[277] Further, the proposed language of 40 CFR § 52.43, which applies to Iron and Steel Mills and Ferroalloy Manufacturing is proposed to include in the definition of "Affected unit" "taconite production kiln."[278]

[275] Air Quality Modeling Technical Support Document, EPA-HQ-OAR-2021-0668-0099 at A-7.

[276] 87 Fed. Reg. at 20,083; see also EPA-HQ-OAR-2021-0665-0191, at 1.

[277] 87 Fed. Reg. 20,046, Table IV.B-4; *id.* at 20,145, Table VII.C-3.

[278] 87 Fed. Reg. at 20,181.

To the extent EPA is including taconite kilns in the Proposed Rule because they are part of "iron and steel mills and ferroalloy manufacturing," this is incorrect. Taconite production is not part of iron and steel or ferroalloy manufacturing. The modeling underlying the Proposed Rule categorizes emission units based on the NAICS Code of the subject facilities. The NAICS code for iron and steel manufacturing is 3311. Metal ore mining, including taconite production, has NAICS code 2122. This is documented in EPA's own modeling data from September 29, 2021. Section 2.5.2 of the RIA describes the industry EPA intended to regulate in the Iron and Steel Mills and Ferroalloy Manufacturing NAICS code:

> Iron is produced from iron ore, and steel is produced by progressively removing impurities from iron ore or ferrous scrap. ***The first step is iron making.*** Primary inputs to the iron making process are iron ore or other sources of iron, coke or coal, and flux.

(emphasis added). This description does not include mining or processing of taconite prior to the iron making process.

It is arbitrary to include taconite kilns in the Proposed Rule because EPA has not modeled the significance of their contribution to any downwind receptor as would be required. Taconite production is not separately mentioned in the Non-EGU Screening Assessment which is EPA's sole basis for determining which industries had a significant enough impact relative to subject to the Proposed Rule. EPA states that that modeling was done on the basis of NAICS code, which would mean that taconite kilns were not included in the modeling of the contributions from the Iron Steel and Ferroalloy industry since as noted above taconite production belongs to a different NAICS code. This is confirmed by the fact that there appear to be no taconite kilns listed in the list of facilities and emission units evaluated as part of the Non-EGU Screening Assessment.[279] Because taconite production was never modeled to be a significant contributor to downwind nonattainment or maintenance issues, it cannot be regulated under the Good Neighbor provision of the CAA. Furthermore, there is no rational basis to treat Taconite as part of the Iron and Steel and Ferroalloy Manufacturing Industry Group. Taconite production is not co-located with iron and steel manufacturing. As a result, there are no taconite production kilns "at an iron and steel mill or ferroalloy manufacturing facility."[280] Taconite production does not use similar processes, have similar emission profiles, or use similar pollution controls. There is no factual basis to conclude that taconite production and iron and steel manufacturing have similar impacts on downwind receptors, similar costs of pollution controls, or should otherwise be grouped together for purposes of screening or regulation under the Proposed Rule.

XXV. Taconite Was Properly Eliminated from EPA's Screening Assessment as a Tier 2 Source Without Significant Boiler Emissions.

[279] Non-EGU Screening Assessment at Table 6; see also excel file in regulatory docket titled "Screening Assessment Non-EGU Facility and Emission Unit Limits List".

[280] *Id.*

While there is no rational basis to include taconite kilns in the Iron and Steel and Ferroalloy Manufacturing Industry Group, EPA did evaluate the Taconite Industry as part of the Metal Ore Mining Industry Group in its Screening Analysis. In doing so, Taconite was appropriate *excluded* from the Proposed Rule.

Specifically, in the "Non-EGU Screening Assessment," the Metal Ore Mining Industry (4-digit NAICS 2122) was originally included as a Tier 2 industry group; however, in a later step in the analysis EPA refined the Tier 2 grouping by identifying potentially impactful industrial, commercial, and institutional ("ICI") boilers, using the projected 2023 emissions inventory in the linked upwind states. This eliminated the Metal Ore Mining Industry Group from the assessment entirely, as EPA found that it had no "potentially impactful" boilers.[281]

Based on EPA's own assessment, therefore, boilers in the Metal Ore Mining industry, which would include the Taconite Industry, do not provide opportunities for NOx emissions reductions that result in meaningful impacts on air quality at downwind receptors.

XXVI. There is No Other Support in the Record for Subjecting the Taconite Industry to Regulation.

The record is notably lacking in any analysis that would support including the Taconite Industry, on its own or as part of the Iron and Steel and Ferroalloy Manufacturing Industry.

As EPA explains in the preamble to the Proposed Rule, "for Taconite Production Kilns, the EPA does not currently have the data to determine appropriate emissions limits that these units could achieve by installing low NO_X burners. Therefore, the EPA is proposing to require the installation of low NO_X burners for Taconite Production Kilns and work practice standards for operating these control technologies to achieve emissions reductions. The EPA is also proposing to require these sources to perform performance tests and establish a unit-specific emissions limit at that time. These work practice standards are consistent with EPA's Taconite FIP for Minnesota.[282] Due to the ongoing nature of this FIP, the EPA is proposing to require installation of specific control technologies and a period of evaluation before setting a numerical emissions limit."[283] This is just another way of saying EPA does not have sufficient data to impose emission regulations and that this data, and the regulations themselves, will come from the Taconite FIP. If EPA lacks the data to regulate now, the only option is to exclude Taconite from regulation. EPA cannot promulgate a "placeholder" rule that simply says EPA will regulate later.

EPA has also not done any of the assessments for Taconite that have been included to support the Proposed Rule for other sources. The data EPA used for its screening assessment did not include taconite kilns.[284] EPA's Screening Assessment identified 489 emission s units with

[281] Screening Assessment at 5; *see also id.* at 6, Table 1: Number of Emissions Unit Types in Tier 2 Industries in the Non-EGU Screening Assessment.

[282] See 81 FR 21671 (April 12, 2016).

[283] 87 Fed. Reg. at 20,146.

[284] EPA-HQ-OAR-2021-0668-0191 Attachment 1.

greater than 100 tpy of NOx emissions at approximately 250 facilities, none of which were taconite kilns or taconite facilities. EPA's estimates of costs did not look at taconite facilities.

Had EPA looked at the costs of regulating the Taconite Industry, it would have been forced to reject the \$7,500/ton threshold suggested by its modeling. Barr has completed an initial draft cost estimate for a retrofit installation of low-NOx burners on one of the U.S. Steel Minntac's Step III 153 MMBTU/hr Natural Gas-Fired Heating Boilers using the Proposed Rule's NOx emission limit for Natural Gas Fired Boilers of 0.08 lb/MMBTU. The preliminary cost estimate shows that if one of Minntac's Step III 153 MMBTU/hr Heating Boilers was retrofitted with a low-NOx burner, the resulting pollution control cost would be ~\$20,000/ton of NOx removed, which exceeds EPA's cost effectiveness threshold of \$7,500/ton. EPA's benefits calculations (EPA-HQ-OAR-2021-0668-0134) did not look at benefits from regulating taconite kilns. EPA's examination of ongoing compliance costs did not look at taconite facilities.[285] Without the relevant data and a satisfactory explanation for its actions, EPA cannot include the Taconite Industry in regulations that are otherwise completely focused on other sources.

XXVII. Excluding Taconite from the Proposed Rule is Proper Because the Proposed Rule Imposes No Limits on the Industry.

NOx emissions from taconite kilns are already regulated by detailed regional haze FIPs covering Minnesota and Michigan.[286] This FIP imposes stringent NOx emission limits based on the installation of low-NOx main burner systems as the best available retrofit technology ("BART"), with specific emission limits and implementation schedules established for each taconite facility based on its own historic performance and retrofit capabilities. Minnesota has noted in prior comments that the Taconite FIP is already responsible for just under 11,000 tons per year in NOx reductions in the State, including 5,700 tons per year from U. S. Steel's Keetac and Minntac facilities.[287] This is a demonstration of the considerable environmental improvements that have already been achieved in Minnesota air quality and interstate transport of NOx from Minnesota. The Proposed Rule recognizes the effectiveness of the Taconite FIP, pointing to the FIP requirements as the very requirements needed by the Taconite industry "to achieve the required emissions reductions [to satisfy the] remaining interstate transport obligations for the 2015 ozone NAAQS."[288] Even if the Taconite Industry were subject to regulation under EPA's Screening Assessment, this finding would support excluding the Taconite Industry from further regulation, because there are no further restrictions needed to prevent significant contribution to nonattainment or interference in maintenance of the ozone NAAQS, and EPA is not permitted to over-control sources.[289]

[285] Information Collection Request, EPA-HQ-OAR-2021-0194 at 4 and 11-12.

[286] 40 CFR §§ 52.1235 and 52.1183 (the "Taconite FIP").

[287] Minnesota SIP Denial Comments at 2.

[288] 87 Fed. Reg. at 20,045.

[289] *EPA v. EME Homer City Generation, LP*, 572 U.S. 489 (2014).

Minnesota has itself urged EPA to "have these significant reductions included in the 2016v2 inventory for non-EGUs" rather than take credit for them in the new FIP.[290] But EPA does not draw the right conclusion from the results of the Taconite FIP. No other non-EGU is subject to this type of double-regulation in the Proposed Rule, and EPA provides no justification for singling out taconite kilns in the Proposed Rule. As with other industries that are not Tier 1 sources and do not have large boilers subject to Tier 2, the Taconite Industry should be excluded from the Proposed Rule.

XXVIII. The Proposed Rule Should Not Incorporate Another FIP by Reference.

As discussed above, the Taconite Industry is already subject to stringent NOx regulations by the Taconite FIP. EPA proposes to re-impose these same requirements in the Proposed Rule, essentially double-counting reductions that have already been mandated by the State of Minnesota and EPA. Specifically, the Proposed Rule nominally includes taconite kilns, erroneously categorized as part of the Iron and Steel and Ferroalloy Manufacturing Industry, but the emission limits in the Proposed Rule for taconite kilns are "Work practice standard[s] to install low NOx technology/burners, test and set."[291] This requirement is explained as being imposed because it is "[c]onsistent with requirements in Minnesota Taconite FIP *See* 81 FR 21671."[292] The proposed rule language is even more explicit, stating that Taconite Production Kilns are to "Install and operate low NOX burners as required by 2013 and 2016 Minnesota FIPs. 40 CFR § 52.1183." 87 Fed. Reg. at 20,181, Table 1 to Paragraph (c).[293] In other words, the Proposed Rule does not impose emission limits on the Taconite Industry. It only incorporates requirements from the already-imposed FIP.

Taking a FIP that has already been imposed for regional haze and recasting it in duplicate form as an ozone transport requirement is inefficient and inappropriate. Rather than imposing a redundant Taconite FIP requirement in the Proposed Rule, EPA should find that, considering the Taconite FIP, no further regulation of the Taconite Industry is needed to address.

XXIX. If EPA Ultimately Incorporates the Taconite FIP in the Proposed Rule, it Must Accurately Reflect the Requirements of the Taconite FIP.

Including the Taconite Industry in the Proposed Rule is at best redundant with the Taconite FIP. At worst, the Proposed Rule will conflict with the Taconite FIP it purports to incorporate, creating confused and potentially inconsistent requirements.

In the Taconite FIP, EPA attempted to impose a single uniform emission limit across all taconite kilns. This resulted in over ten years of litigation, which is still ongoing, and multiple

[290] Minnesota SIP Denial Comments at 2.

[291] 87 Fed. Reg. 20,046, Table I.B-4 and 20,145, Table VII.C-3.

[292] *Id.* at Table VII.C-3.

[293] The Proposed Rule's citation is incorrect. 40 CFR § 52.1183 is the Michigan regional haze FIP. The Minnesota FIP is at 40 CFR § 52.1235. This reference also ignores the 2021 Minnesota FIP, which addressed Minntac. See 86 Fed. Reg. 12,106 (March 2, 2021).

revisions to the Taconite FIP to incorporate the unique circumstances of each facility.[294] Additional revisions are anticipated following negotiation of revised language for U. S. Steel's Keetac facility.

In attempting to paraphrase the Taconite FIP in a single line, the Proposed Rule falls into the same error. The Proposed states that taconite kilns will "install, maintain, and continuously operate low-NO_X burners to reduce existing average NO_X emissions from the facility by 40% during all periods of kiln operation."[295] This language is nowhere in the Taconite FIP. Rather, the Taconite FIP sets out a detailed and comprehensive plan for establishing achievable emission limits for a variety of taconite production kilns. Minnesota has itself estimated that reduction from low-NOx burners to range from 2%-65% based on the emission unit.[296]

The language used in the Proposed Rule is also far too vague to serve as a regulatory requirement. The Proposed Rule provides no process for calculating "existing average NO_X emissions from the facility."[297] The Proposed Rule provides no support for its derivation of a 40% NOx reduction at all taconite kilns. As noted above, EPA previously attempted to impose uniform emission limits on all taconite furnaces. The result was ten years of litigation and multiple rounds of rulemaking revisions to arrive at case-by-case, unit specific emission limits for the taconite industry that have been demonstrated achievable based on actual emissions data.

The Proposed Rule does not recognize that Minntac's Taconite FIP requirements were expressly negotiated to be an aggregate emission limit across five kilns, not a single reduction at each kiln.[298] The Proposed Rule improperly directs that a specific technology by used at taconite kilns (low-NOx burners). In both the Taconite FIP and for all other sources in the Proposed Rule, emission limits are set based on available technologies, but each source is free to achieve the limit based on any combination of emission controls. For facilities that have not yet installed low-NOx burners, the Proposed Rule provides for using data from "within five years of the effective date of this rule to be used as baseline emission testing data providing the basis for required emission reductions."[299] This ignores the test-and-set schedules established in the Taconite FIP for many facilities.[300] U. S. Steel and EPA are currently negotiating a revised limit for Keetac that would include its own implementation schedule, which may or may not match that of the Proposed Rule.

The operating, monitoring, and recordkeeping requirements in the Proposed Rule are all drafted on the assumption that there is an applicable emission limit for the regulated unit. Requirements that a facility use CEMS to "monitor compliance with the emissions limits set forth

[294] *See* 81 Fed. Reg. 21,687 (April 12, 2016); 86 Fed. Reg. 12,106 (March 2, 2021).

[295] 87 Fed. Reg. at 20,182.

[296] EPA-R05-OAR-2022-0006-0011-attachment_1.

[297] 87 Fed. Reg. at 20,182.

[299] 87 Fed. Reg. at 20,182.

[300] *See, e.g.*, 40 CFR 42.1235(b)(ii)(A)(2).

in Table 1 to paragraph (c) of this section," or record 30-day averages "in excess of the applicable NOx emission limit in Table 1 to paragraph (c)" do not make sense if there is no numeric emission limit imposed in Table 1 to paragraph (c).[301] Similarly, the Proposed Rule's requirement that taconite kilns "continuously operate NOx control devices as necessary to achieve emission limits set forth in Table 1 to paragraph (c) of this section" makes no sense in the context of the Taconite FIP.

Finally, the Proposed Rule goes beyond EPA's authority when it requires taconite kiln operators to "continuously operate low-NOx burners to reduce existing average NO_X emissions from the facility by 40% during all periods of kiln operation" in order to prevent contribution or interference with an ozone NAAQS that are justified throughout the rulemaking only for the ozone season.

The Proposed Rule not only needlessly restates requirements that are already reflected in the Taconite FIP, it adds confusion and either undoes, or redoes, without sufficient information or support, evaluations and productive efforts that have occurred for over 10 years and that have resulted in significant NOx reductions that have been shown to be technologically and economically feasible. This is needless overregulation and should be removed from the Proposed Rule.

XXX. Minntac and Keetac Modeling Corrections Are Required

Minntac is modeled to emit 3,900-4,167 tpy from 2032 to 2023. September 29, 2021, Emissions Data. Minntac has already committed, as reflected in its 2013 title V permit, to reduce emissions to 3,990 tpy as an annual cap on all facility NOx emissions.

Keetac is project to emit 4,631-4,949 tpy. According to the 2016 Barr Engineering analysis submitted to EPA, baseline calculations of Keetac data should not be based on recent emissions data because it is not representative of the mix of fuels the Keetac furnace is permitted to burn. Even so, a far more representative baseline is 3,455 tpy for uncontrolled NOx emissions.

SPECIFIC COMMENTS RELATED TO STATE IMPLEMENTATION PLANS

XXXI. The Proposed Rule Does Not Provide Adequate Deference to State Approaches to Regulation of Interstate Transport of NOx, as Required by the Principles of Cooperative Federalism Contained in the Clean Air Act.

State primacy in developing implementation plans and the opportunity to cure perceived defects in implementation plans are two examples of a broader theme of cooperative federalism that runs throughout the Clean Air Act. *See Bell v. Cheswick Generating Station*, 734 F. 3d 188, at 190 (3rd Cir. 2013) (The Clean Air Act "employs a 'cooperative federalism' structure under which the federal government develops baseline standards that the states individually implement and enforce."); *Michigan v. EPA*, 268 F.3d 1075, 1083 (D.C. Cir. 2001) (the Clean Air Act "is an experiment in cooperative federalism"); *see also Am. Trucking Ass'ns v. EPA*, 600 F.3d 624, 625

[301] 87 Fed. Reg. at 20,182.

(D.C. Cir. 2010) (under the Clean Air Act, "both the Federal Government and the States . . . exercise responsibility for maintaining and improving air quality"). As Justice Kennedy stated in dissent in *Alaska DEC v. EPA*:

> If cooperative federalism is to achieve Congress' goal of allowing state governments to be accountable to the democratic process in implementing environmental policies, federal agencies cannot consign States to the ministerial tasks of information gathering and making initial recommendations, while reserving to themselves the authority to make final judgments under the guise of surveillance and oversight.
>
> 540 U.S. 461, 518 (2004) (internal citation omitted).

In proposing the FIP, EPA totally obviated Congress' intentions that the Clean Air Act be implemented across the county in a manner that uses cooperative federalism. Instead, EPA unilaterally rejects the State's approaches to regulating interstate transport of NOx originating within their borders, and would impose EPA's own, unproven and infeasible, preferred approach to fulfil the Clean Air Act ozone transport requirements. In doing so, EPA improperly treated the state SIPs are mere "initial recommendations" over which EPA could impose its own "final judgments under the guise of surveillance and oversight."

No state has proposed the type, scope, or stringency of emission limitations contained in the Proposed Rule. This is particularly notable in the context of the NAAQS, which do not require limitation of any particular industry, emission source, or use of any particular control technology to achieve the interstate transport obligations of CAA § 110. This wholesale rejection not just of the states' findings, but their entire approach to regulating emissions within their borders, particularly when combined with the lack of any opportunity for the states to reasonably comment on the denials of their SIPs and amend them in light of EPA's perceived deficiencies, demonstrates a lack of deference to the fundamental principles of cooperative federalism embodied in the Clean Air Act and further cautions against EPA proceeding with the Proposed Rule.

XXXII. EPA is Exceeding its Statutory Authority by Issuing the FIP while Disregarding Approvable SIPs.

EPA does not have authority to impose a FIP when adequate and approvable SIPs have been submitted to EPA.

Under the Clean Air Act, states are given primacy in developing implementation plans for compliance with the national primary and secondary ambient air quality standards. *See* 42 U.S.C. § 7410; *see also Train v. NRDC*, 412 U.S. 60, 79 (1975) (EPA is "relegated by the [Clean Air] Act to a secondary role in the process of determining and enforcing the specific, source-by-source emission limitations which are necessary if the national standards it has set are to be met."). This includes meeting the interstate transport requirements of "prohibiting, consistent with the provisions of this subchapter, any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will—(I)contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any such national primary or secondary ambient air quality standard, or (II)interfere with measures required to be included in the applicable implementation plan for any other State under part C to prevent significant deterioration of air quality or to protect visibility." 42 U.S.C. § 7410(a)(2)(D)(i).

Only when the state does not submit a compliant SIP, and the Administrator either "(A) finds that a State has failed to make a required submission or finds that the plan or plan revision submitted by the State does not satisfy the minimum criteria established under subsection (k)(1)(A), or (B) disapproves a State implementation plan submission in whole or in part," does EPA have authority to promulgate a FIP. 42 U.S.C. § 7410(c); *see also Train*, 412 U.S. at 79 ("Under § 110(a)(2), the Agency *is required* to approve a state plan which provides for the timely attainment and subsequent maintenance of ambient air standards, and which also satisfies that section's other general requirements.") (emphasis added).

Nineteen states, including the states of Arkansas, Illinois, Indiana, Michigan, Minnesota, Ohio, and Pennsylvania, have submitted SIPs that meet the requirements of the Clean Air Act and should be approved. Instead of meeting its statutory obligation to review these previously-submitted SIPs, EPA ignored them for years. Now, subject to a short deadline imposed under a consent decree, EPA proposed wholesale disapprovals of these plans without adequate justification and contrary to the mandate of § 110(a)(2) of the Clean Air Act shortly before proposing the FIP in the Proposed Rule.

EPA has not yet finalized its disapprovals and has given the states no opportunity to correct any deficiencies that EPA purports they contain. While EPA has found that some states have not submitted SIPs, for many states, EPA has only proposed disapproval or is still reviewing the state plans. 87 Fed. Reg. at 20,040 (for certain states, "the EPA has proposed, but has not finalized, actions disapproving good neighbor SIP revisions. And for other states, the EPA has not yet proposed action on their good neighbor SIP submittals, but these submittals are currently under review, and EPA intends to act on these submittals in the coming months"). In doing so, the Proposed Rule improperly supplants states' primary authority and would put EPA's preferred ozone approach over the states' own adequate and approvable implementation plans. This is beyond EPA's authority.

EPA's proposed denial of the SIPs is addressed at length in the comments submitted on EPA's proposed SIP denials, including U. S. Steel's own comments on the proposed denials of the Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin SIPs (EPA-R05-OAR-2022-0006-0017) and the Arkansas SIP (EPA-R06-OAR-2021-0801-0043). These comments are equally relevant to the Proposed Rule, and U. S. Steel incorporates them by reference.

As demonstrated in those comments, EPA's proposed SIP denials are not based on proper grounds. Rather, they are based on:

1. Improperly rejecting state assessments of whether in-state emissions were significantly contributing to or interfering with maintenance of downwind attainment of the ozone NAAQS that were not only well within the State's discretion as primary regulators, but consistent with EPA's own published guidance.

2. Moving the goal posts for regulation by creating new modeling after SIPs were already submitted, creating a standard no state could possibly meet.
3. Erroneously relying on incomplete and inaccurate emissions data.

Correcting these issues will demonstrate that EPA does not have grounds to disapprove the previously-submitted SIPs, including the SIPs or Arkansas, Illinois, Indiana, Michigan, Minnesota, and Ohio, and that the Administrator does not have authority to promulgate the proposed FIP.

XXXIII. EPA Does Not Have the Authority to Mandate Emission Limits by Disapproving Adequate SIPs and Imposing its own FIP.

In *Train v. NRDC*, 412 U.S. 60, 79 (1975), the U.S. Supreme Court made clear that states have the authority under the Clean Air Act to develop the specific emission limitations that will ensure compliance with the NAAQS in the first instance. As the Court later stated in *Union Elec. Co. v. EPA*, "Congress plainly left with the States, so long as the national standards were met, the power to determine which sources would be burdened by regulation and to what extent." 427 U.S. 246, 269 (1976); *see also id.* at 267 (states have "virtually absolute power in allocating emission limitations so long as the national standards are met"). In light of the Supreme Court's holdings, the D.C. Circuit has held that the validity of EPA's own NAAQS program "depends in part on whether the program in effect constitutes an EPA-imposed control measure or emission limitation triggering the *Train-Virginia*[302] federalism bar: in other words, on whether the program constitutes an impermissible source-specific means rather than a permissible end goal." *Michigan v. EPA*, 213 F.3d 663, 687 (D.C. Cir. 2000) (internal alterations omitted).

In denying SIPs that adequately prevented significant contribution to nonattainment and interference with the NAAQS and supplanting these state-level approaches with a FIP that imposes EPA's preferred method of achieving the same goal, EPA's Proposed Rule supplants the states' role as primary decider of "which sources would be burdened by regulation and to what extent." This violates the federalism bar established in *Train* and *Virginia v. EPA*.

XXXIV. EPA Has No Authorization to Promulgate a FIP before Disapproving a SIP.

In the Proposed Rule, EPA has not even allowed time to finish deciding whether to disapprove the many ozone transport SIPs submitted for its review. Instead, EPA is accepting comments almost simultaneously both for disapproval of the SIPs and approval of EPA's proposed FIP. In fact, for some states EPA had not even proposed to disapprove the SIP submission before proposing the FIP. This is unlawful because the relevant statute only permits EPA to "promulgate a Federal implementation plan . . . after the Administrator . . . disapproves a State implementation plan submission."[303]

Contrary to EPA's assertion, no court decision has ever authorized EPA to propose a FIP before taking the predicate final action of disapproving a SIP in the states the FIP is proposed to

[302] *Virginia v. EPA*, 108 F. 3d 1397 (D.C. Cir. 1997).

[303] 42 U.S.C. 7410(c)(1)(B) (emphasis added).

cover.[304] In fact the D.C. Circuit expressly reserved judgement on this very issue the last time it was raised before the D.C. Circuit, dismissing it on administrative exhaustion grounds rather than approving EPA's approach. [305] Nor does the Supreme Court's opinion in *EME Homer* address this issue, as that opinion only determined that EPA need not provide States an additional opportunity to revise its SIP after disapproval of a SIP, not whether a FIP can be issued before disapproving a SIP in the first place.[306] If EPA does proceed with SIP denials, in the interest of cooperative federalism and in furtherance of the Clean Air Act itself, EPA should allow a reasonable time for States to address the grounds for denial before EPA promulgates a FIP.

XXXV. EPA Cannot Lawfully Issue FIP and Disapprove SIPs Based on Data Not Available at Time SIP Submissions Were Required.

As noted in the State of Arkansas' comments on EPA's proposed denial of Arkansas' proposed Good Neighbor SIP provisions for the 2015 Ozone NAAQS, EPA reevaluated the significance of contributions to downwind receptors based on data generated *after* the statutory deadline for EPA to act on approving or disapproving the Arkansas Transport SIP submission.[307] Had EPA reviewed the SIP in the timeframe required by federal law, the information available at the time—the same information that states used to inform their decisions—would not have supported a decision to disapprove the SIP for Arkansas, and subsequently would remove any statutory basis for EPA to promulgate a FIP for Arkansas. Although the D.C. Circuit has held that EPA has legal authority to propose a FIP at the same time it disapproves a SIP submission without giving the State an opportunity to fix the deficiency in the SIP submission, we are aware of no decision or statutory basis that would allow EPA to do so based on data that was unavailable to the State at the time that it made its SIP submission. On the contrary, "It is one thing to expect regulated parties to conform their conduct to an agency's interpretations once the agency announces them; it is quite another to require regulated parties to divine the agency's interpretations in advance or else be held liable when the agency announces its interpretations for the first time . . . and demands deference." [308] Accordingly, it was unreasonable and unlawful for EPA to disapprove the Arkansas submission based on data that the agency did not generate until after its statutory deadline to act on the Arkansas Transport SIP. Because EPA erred in denying the Arkansas Transport SIP, it was also not lawful for EPA to propose the Proposed Rule FIP to

[304] Contra Proposed Rule at 20,057.

[305] *EME Homer City Generation, L.P. v. E.P.A.*, 795 F.3d 118, 132 (D.C. Cir. 2015) ("petitioners argue that EPA did not have authority to promulgate certain Transport Rule FIPs because those FIPs were signed by the EPA Administrator before EPA published its disapproval of the CAIR SIPs in the Federal Register. Petitioners did not raise this issue before the Agency during notice and comment, and EPA has not denied any petition for reconsideration raising this objection. We therefore may not entertain it now").

[306] *EPA v. EME Homer City Generation, LP*, 572 U.S. at 509 & n.14.

[307] See Comment submitted by Arkansas Department of Energy and Environment, Division of Environmental Quality, on EPA-R06-OAR-2021-0801-0001, at 3-4 (April 22, 2022).

[308] *Christopher v. SmithKline Beecham Corp.*, 567 U.S. 142, 158-59 (2012).

cover Arkansas, since EPA only has the authority to issue a FIP if a state failed to submit an approvable SIP or EPA properly disapproved it.[309]

XXXVI. Requirements For EPA SIP Review.

EPA states that "In order to replace the non-EGU portion of the FIP in a state, the state's SIP must provide adequate provisions to prohibit an equivalent or greater amount of NOx emissions that contribute significantly to nonattainment or interfere with maintenance of the 2015 ozone NAAQS in any other state. The non-EGU requirements of the FIP would remain in place in each covered state until a state's SIP has been approved by the EPA to replace the FIP."[310] This is not reasonable or lawful for multiple reasons.

First, a state's ability to replace the FIP must be tied to whether it has addressed the underlying nonattainment/maintenance concerns by reducing significant contribution from sources in the state below the significance threshold, (as opposed to whether it prohibits equivalent emissions to the FIP). For instance, if Arkansas is able to show that it no longer has a significant contribution to the Brazoria receptor before the final FIP deadline for non-EGU emission reduction standards (whether due to White Bluff closure or otherwise), then there would no longer be any statutory basis for EPA to impose a Good Neighbor FIP on Arkansas.

Second, given that the limits imposed in the Proposed Rule are not the same as the statewide emission reductions that EPA modeled as being sufficient to resolve any significant contribution to nonattainment or interference with maintenance of the 2015 ozone NAAQS in downwind states, as explained in detail above, EPA cannot rationally judge a SIP based on whether it reduces emissions by a greater amount than the Proposed Rule's limits would. Rather, EPA's evaluation of any SIP could not require the SIP to result in more reductions than the amount of statewide emission reductions EPA actually modeled as resulting in attainment for linked receptors. i.e., the total amount specified at the Non-EGU Screening Assessment at Figure 2.

CONCLUSION

For the reasons set forth above U.S. Steel urges that EPA withdraw the Proposed Rule in favor of allowing states the opportunity to correct any concerns that EPA may have with their SIP submittals and in the alternative for EPA to correct the errors that have been identified with respect to its Proposed Rule. If EPA makes significant changes to the Proposed Rule, which are needed, then U. S. Steel requests the opportunity to be involved in a stakeholder process and to have adequate to review and comment on any changes.

U. S. Steel appreciates the opportunity to provide comments on the Proposed Rule. If you have any questions or should you need additional information, please do not hesitate to contact me at 479-200-9743 or kjones@uss.com.

RE: EPA's Modeling Does not Sufficiently Demonstrate that Big River Steel Is a Significant Contributor to Ozone Problems at Brazoria, TX

In the following memorandum, we offer our opinion regarding the Environmental Protection Agency (EPA) proposed rule, "Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standard" (87 FR 20036, April 6, 2022, herein the "Proposed Rule"). We reviewed multiple documents, memorandum, and data sets related to the Proposed Rule found in the associated docket and/or provided by EPA via email and external hard drives. Our purview was restricted to the modeling and technical approach of determining significance of impact of Nitrogen Dioxide (NOx) emissions from the Big River Steel (BRS) facility in Osceola, Arkansas (AR). Our opinion based on the discussion below is succinctly summarized as the following:

EPA's modeling in support of the Proposed Rule does not sufficiently demonstrate that NOx emissions from Big River Steel significantly contribute to Ozone concentrations at the monitor in Brazoria County, Texas (TX).

1. OVERVIEW OF EPA'S FINDING RELATIVE TO BRS

During the Cross-State Air Pollution Rule (CSAPR) Update (Final October 2016), EPA developed a four-step framework to address requirements of the good neighbor provision for the 8-hour Ozone National Ambient Air Quality Standard (NAAQS): 1) identify downwind air quality problems; 2) identify upwind states that contribute enough to those downwind air quality problems to warrant further review and analysis; 3) identify the emissions reductions necessary (if any), considering cost and air quality factors, to prevent an identified upwind state from contributing significantly to those downwind air quality problems; and 4) adopt permanent and enforceable measures needed to achieve those emissions reductions.

EPA performed state-level photochemical grid modeling using the Comprehensive Air Quality Model with Extensions (CAMx)[1] showing projected 2026 AR NOx emissions could result in a predicted contribution at one downwind receptor (the Brazoria County, TX Ozone monitor, EPA number 480391004, hereafter referred

---

[1] CAMx Model. https://www.camx.com/; accessed May 2022.

to as Brazoria) above 1 ppb (the current Ozone Significant Impact Level, or SIL) and 1% of the 2015 Ozone NAAQS. EPA thus concluded that projected AR NOx emissions in 2026 may contribute to the Brazoria, TX monitor's maintenance of attainment of the 2015 Ozone NAAQS in 2026. No other monitors projected by EPA to be "linked" to AR were shown to be in nonattainment or maintenance beyond 2023. In EPA's view, this conclusion satisfied the first two steps of the four-step framework: projected NOx emissions (2026) from AR NOx sources resulted in potential Ozone issues at a downwind out-of-state receptor (Brazoria, TX).

With AR presumably identified after steps one and two of their framework, EPA looked to satisfy step three, "identify the emissions reductions necessary (if any), considering cost and air quality factors, to prevent an identified upwind state from contributing significantly to those downwind air quality problems", by extrapolating modeling results to estimate impacts at any out-of-state ("downwind") receptor due to NOx emissions from several industries in multiple states. One of those industries evaluated was the AR steel industry, within which BRS is one facility.

To arrive at an estimate of the downwind impacts from the AR steel industry EPA used state-level modeled results for the future year 2023 from their previously performed modeling in support of the CSAPR Update[2] in combination with an emissions inventory developed as part of EPA's "2016v2 Platform"[3]. The CSAPR Update modeling results were based on an older version of the emissions platform (2016v1). For the Proposed Rule, the older CSAPR Update modeling of each state's NOx emissions for year 2023 (using projected emissions) were extrapolated to estimate the contribution from several industries within each state. Based on the extrapolated industry-level results, EPA developed control scenarios for industry-level units such that presumed downwind air quality issues would be mitigated by 2026 (2023 being deemed too soon to reasonably facilitate installation of controls). Those mitigation scenarios would be applicable to BRS, and future expansion plans associated with BRS under the Proposed Rule. The schematic in **Figure 1** represents our understanding of the general approach EPA took to begin to their four-step framework.

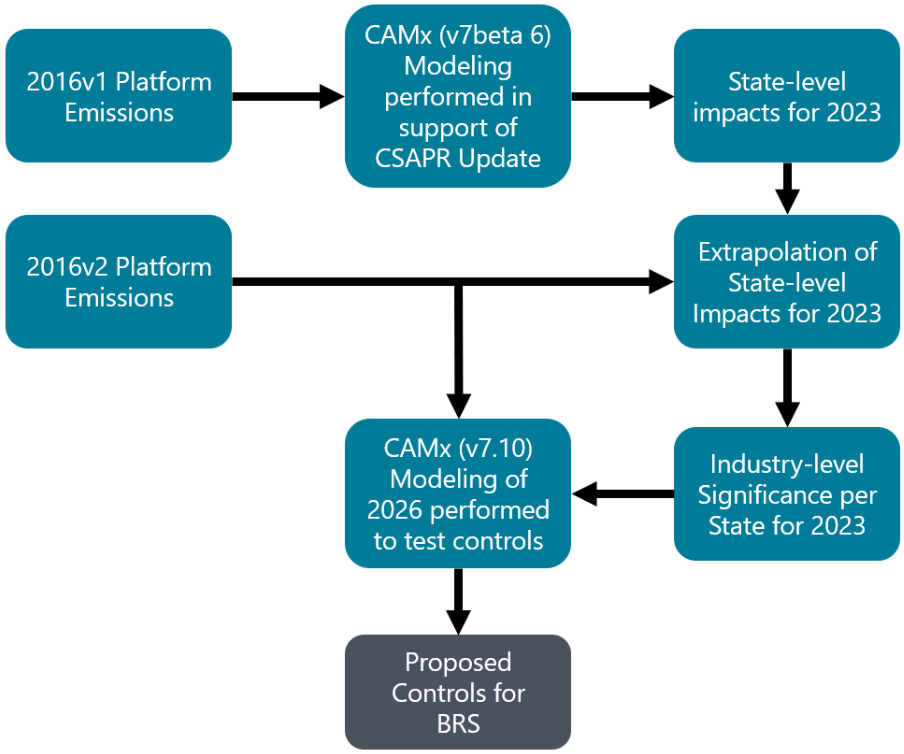
Figure 1: Estimated Schematic of EPA's Approach to Determine Industry-level Significance and Inform BRS NOx Emission Controls



In general, the basis for the Proposed Rule's mandate to control NOx emissions from BRS should hinge sharply on the determination that BRS's NOx emissions significantly contribute to levels of Ozone at Brazoria above the 8-hour Ozone NAAQS. This determination was never reached nor approached by EPA in the Proposed Rule. Instead, EPA considered extrapolations of state-level Ozone contributions and then, across all evaluated states, imposed controls on all sources within an industry that EPA believed could contribute to Ozone issues if that industry showed at least one instance of extrapolated significance nationally. In the discussion below, various components of EPA's technical approach to determine significance of BRS's NOx emissions relative to the Ozone concentrations at Brazoria are evaluated, and opinions offered regarding the appropriateness of EPA's findings.

2. EPA'S DATA AND THE SIGNIFICANCE OF BRS

2.1 EPA's Technical Approach Is Disconnected from EPA's Goal of Determining Significance.

In the Proposed Rule, EPA is aiming to "*provide states with as much information as the EPA can supply at this time to support their ability to submit SIP revisions to achieve the emissions reductions the EPA believes* *necessary to eliminate significant contribution [to downwind Ozone air quality issues].*"[4] EPA's responsibility under section 110 of the Clean Air Act is to mitigate emissions that ***significantly*** contribute to nonattainment or interference with maintenance of the 2015 Ozone NAAQS. The scope of their emission mitigation mandate is bounded by the ***significance*** of contribution of those emissions, such that "*reductions unnecessary to downwind attainment anywhere fall outside the Agency's statutory authority*"[5], thus prohibiting "over control" of emissions based on insignificant impacts. The ***significance*** of BRS's NOx emissions to out-of-state Ozone concentrations at a monitor roughly 850 kilometers away (Brazoria) is thus a critical question. EPA's task then, in advance of mandating controls on BRS based on Ozone predicted concentrations at Brazoria was to robustly determine the significance of BRS's NOx emissions to downwind Ozone air quality issues at Brazoria. Based on the elements of approach described below, our opinion is that EPA did not sufficiently determine the significance of BRS's NOx emissions relative to Ozone attainment at Brazoria or at any monitor.

2.2 EPA Did Not Model BRS NOx Emissions Yet Deemed Them Significant.

The main component of EPA's determination of the significance of downwind Ozone contributions from the steel industry's NOx emissions is not based on direct modeling or apportionment of the steel industry. Rather, as described in **Figure 1**, that determination of industry-level significance was made based on obsolete state-level modeling and extrapolations using outdated emission inventories. That industry-level significance was then applied to facilities within "significant" industries broadly. In other words, EPA found that the steel industry's NOx emissions were significant, thus all evaluated state's steel industries' NOx emissions were significant, thus AR's steel industry was significant, thus BRS's NOx emissions were significant. However, from all appearances and based on our understanding of the data made available by EPA, nowhere in the CAMx modeling steps described in **Figure 1** (the older CSAPR update modeling to determine industry-level significance or the Proposed Rule's modeling to test control scenarios of those "significant" industries) were BRS's NOx emissions considered. EPA has deemed BRS NOx emissions significant without ever having tested their significance via modeling.

The modeling performed by EPA in support of CSAPR to determine BRS's significance by way of extrapolation used the 2016v1 EPA emission platform; the modeling performed by EPA to test control scenarios of significant industries used the 2016v2 EPA emission platform. Neither of these platforms include BRS NOx emissions. The 2016v1 and 2016v2 EPA emissions platforms consist of inventory "cases" that represent the years 2016, 2023, 2026, and 2032 with the abbreviations 2016fj, 2023fj, 2023fj, and 2032fj, respectively. The abbreviation gives insight into the foundational source of the emissions data from which the projected future-year inventories are derived: in the abbreviation 2026fj_16j, 2026 is the year represented by the emissions (a future year in this case, developed by projection factors); the "f" represents the base year emissions modeling platform iteration – "f" was developed from the 2014 National Emission

[4] Proposed Rule "Executive Summary".

[5] EPA v. EME Homer City Generation, L.P., 572 U.S. 489 (2014).

Inventory (NEI); the "j" stands for the tenth configuration of emissions modeled for that modeling platform.[6] For all inventories with the "f" base year, BRS was not featured. This is due to BRS not becoming active until well into 2015. **Table 1** presents our understanding of EPA's emissions platforms used in CAMx modeling, the application of the results of that modeling, and whether BRS NOx emissions were included. EPA's approach to determine significance NOx emissions from states (e.g., AR) and industries within those states (e.g., the steel industry) and the determination and testing of NOx control scenarios does not include BRS's NOx emissions.

Table 1: Summary of Emissions Cases Used in EPA CAMx Modeling

EPA Emissions Platform	Emissions Case Used In EPA CAMx Modeling	EPA Application of Results	Were BRS NOx Emissions Included?
2016v1	2016fj	Baseline case	No
2016v1	2023fj	Determination of significant states and significant industries in those states	No
2016v2	2026fj	Determination of industry specific control scenarios	No

Table 2 presents an excerpt from EPA's summary of NOx emissions from non-Electricity Generating Unit (Non-EGU) point sources used in the modeling as shown in inventory data provided within the Proposed Rule docket. EPA used no BRS emissions under inventory 2023fj (EPA's basis for significance modeling) nor in inventory 2026fj (EPA's basis for the control testing modeling). BRS NOx emissions do appear in other inventories (2017gb, 2018gc, 2019 NEI20210914), however, these inventories noted by EPA as not having been modeled[7].

Table 2: Summary of BRS NOx Emissions Inclusion in EPA Non-EGU Inventories

Facility Name	Facility ID	Pollutant	2016fj tpy	2017gb tpy	2018gc tpy	2019NEI 20210914 tpy	2023fj tpy	2026fj tpy	2032fj tpy
Big River Steel LLC	18122211	NOX	-	283.41	290.19	273.74	-	-	-

Further, **Figure 2** presents a mapping of the emission sources in northeastern AR that were included in EPA's 2016v2 emissions platform (which were used in EPA's control scenario modeling). Yellow dots indicate AR sources included. BRS was not present (noted by blue dot location). Thus, EPA has applied significance

[6] EPA Document EPA-HQ-OAR-2021-0668-0064. Technical Support Document (TSD): Preparation of Emissions Inventories for the 2016v2 North American Emissions Modeling Platform.
[7] EPA Document EPA-HQ-OAR-2021-0668-0105, Content PDF: "while 2017, 2018, and 2019 data provided for additional context although 2017-2019 were not modeled."

to BRS's NOx emissions, and arrived at control scenarios for BRS without ever having performed modeling capable of demonstrating that significance.

Any inference in the Proposed Rule as to the significance of BRS's NOx emissions relative to the Ozone concentrations at Brazoria is based on modeling that did not consider BRS's NOx emissions and is inconsequential.

Figure 2: EPA 2016v2 Emissions Sources in Northeast Arkansas

2.3 EPA Used Extrapolations of Obsolete Modeling Results Based on an Inaccurate Emissions Inventory.

The state-level modeling performed in support of the CSAPR Update that was relied on for the determination of significance of the steel industry and thus BRS used an obsolete "beta" version of CAMx (version 7beta 6), an obsolete version of the Weather Research and Forecasting Model (WRF, version 3.8, released in 2016; WRF is now at version 4.4) and an older obsolete emissions inventory (2016v1)[8]. Version "7beta 6" was a pre-release of CAMx version 7.00, which has been flagged by the model developer as a version with "several critical bugs associated with major updates to the input files"[9] and that organizations using CAMx should "use later versions." EPA's CAMx model was a "beta" pre-release version of 7.00 and thus contained these critical bugs. Since that time, multiple versions of CAMx with corrective updates have been issued by the developer (version 7.10 in January 2021 and recently version 7.20 in May of 2022). EPA should have updated the modeling with a corrected version of CAMx or could have used EPA's own photochemical grid model that they provide ongoing development support for, the Community Multi-scale Air Quality Model (CMAQ) model[10], which they used for other aspects of the modeling study (development of initial and boundary concentrations).

Were an applicant to use an obsolete model with listed "bugs" by the developer while a valid alternative was available and incorporated obsolete emissions to determine the significance of a facility, EPA would reject any results submitted for review and require the applicant use the latest version of an approved alternative model and relevant representative emissions[11]. In addition, EPA recently disapproved of a state's implementation plan regarding the 2015 8-hour Ozone NAAQS on the basis that in forming their opinion on downwind significance, the state relied on older data and modeling[12]. EPA disapproved of the state's finding relative to significance since the modeling data used was obsolete. EPA is not holding their modeling to the same rigor with which they hold applicants or states. In using the older CSAPR Update modeling which relied on a model with known errors and obsolete emissions, EPA did not use the latest

version of an approved alternative model and did not use relevant representative emissions to determine significance of industries.

EPA leveraged obsolete information (old model and old emissions) and made extrapolations of that information to determine industry-level significance of NOx emissions to downwind Ozone problems and then applied that industry-level significance to BRS. Those industry-level extrapolations were based on the 2016v2 emissions platform, which has been shown to have substantial errors[13]. EPA's stated reason for why they used obsolete models (CAMx 7beta 6, WRF 3.8) incorporating obsolete emissions (2016v1) to feed their industry-level extrapolations applied to BRS was "*the air quality modeling for this proposed rule was not completed in time to support the assessment.*"[14] Photochemical grid modeling is highly complex and takes substantial time to perform, especially to arrive at explicit facility-level impacts. EPA did not have time to complete the appropriate quality of modeling to support the determination of facility or industry-level significance, and thus relied on obsolete modeling with known bugs and extrapolations of that modeling based on inaccurate data (2016v2 emissions) to determine significance of industries in each state and applied that significance to facilities like BRS. Instead of moving forward with a determination of significance that would not pass their own thresholds of appropriateness with which they judge applicants' modeling analyses, EPA should have performed the explicit state, industry, and facility-level modeling using latest model versions and appropriate emissions to appropriately determine the significance of NOx emissions from industrial facilities.

Any inference in the Proposed Rule as to the significance of BRS's NOx emissions relative to the downwind Ozone concentrations at Brazoria is based on extrapolations of obsolete modeling data using inaccurate emissions that don't reflect BRS and is inconsequential.

2.4 EPA Defines 0.01 Ppb as A Threshold of Significance by Subjective Visual Interpretation of a Histogram Plot.

To determine whether AR steel industry's NOx emissions were significantly contributing to downwind Ozone concentrations at monitors, EPA defined a new (and heretofore unused in regulatory applications or review) threshold concentration, 0.01 ppb of Ozone. EPA has previously definitively stated that 1 ppb is a threshold of significance at the project level for the 2015 Ozone NAAQS (8-hour Ozone SIL)[15]. In other words, a single project's emissions could result in downwind Ozone concentrations up to 1 ppb before even that single project was considered significant. However, in the Proposed Rule, EPA defined a substantially more

[13] Arkansas Division of Environmental Quality Comments; Docket No. EPA-R06-OAR-2021-0801, April 22, 2022.

[14] Proposed Rule, footnote 161.

[15] EPA, Guidance on Significant Impact Levels for Ozone and Fine Particles in the Prevention of Significant Deterioration Permitting Program. https://www.epa.gov/sites/default/files/2018-04/documents/sils_policy_guidance_document_final_signed_4-17-18.pdf. Accessed May 2022.

stringent level of significance for the entirety of an industry (not just a single project) within a state. While a single AR steel project could have been deemed insignificant with respect to contribution to Ozone problems by adherence to the EPA's 2015 Ozone SIL of 1 ppb, the entire AR steel industry would now be deemed significant by a downwind concentration of only 0.01 ppb, a level ***100 times lower*** than the official SIL. This stringency is unfounded and would require a substantial amount of supporting analysis (e.g., statistical analysis evaluating the variation in the Ozone 8-hour design value at each monitoring site across the nation) to prove that 0.01 ppb is indeed a threshold above which out-of-state NOx emissions would significantly impact Ozone attainment. EPA has published guidance to instruct other agencies on how to determine and justify Ozone significance values if proposed as an alternative to EPA's 1 ppb level[16]. EPA did not follow their own guidance in this case.

The required quality of supporting analysis was not performed by EPA to arrive at 0.01 ppb. Instead, the analysis used to determine this increased level of stringency beyond the existing 1 ppb SIL was a visual interpretation of a histogram plot. EPA described it thus

> *Initially, there is a fairly steep drop in contributions with a breakpoint between roughly 0.04 and 0.06 ppb followed by a steady decline to 0.01 ppb. Beyond 0.01 ppb the shape of the distribution is much flatter. The data suggest that perhaps 0.05 ppb or 0.01 ppb could serve as breakpoints in the data. Based on the distribution, the 0.01 ppb provides a meaningful conservative breakpoint for screening out non-impactful industries from the Non-EGU analysis in this proposed rule.*[17]

Figure 3 presents the histogram used in EPA's threshold of significance "analysis." In the histogram, each bar represents the maximum contribution to a downwind receptor from a particular industry. EPA did not readily disclose the industries in this analysis in order to provide greater resolution of the shape of the distribution at the lower end of the values. EPA's determination based on their visual interpretation of a ranked histogram is that a 0.01 ppb concentration resultant from AR's steel industry will significantly impact a downwind receptor (like Brazoria) attaining or maintaining the Ozone NAAQS because in general there are few industries that result in Ozone concentrations lower than 0.01 ppb out of state. This argument is not an argument for significance. EPA has not rigorously demonstrated that 0.01 ppb is significant relative to the Ozone NAAQS. EPA has only demonstrated that 0.01 ppb is a subjective level of reference below which few industries have resultant concentration impacts. EPA should have used their previously determined level of significance of 1 ppb for the 2015 Ozone NAAQS.

[16] EPA, Guidance on Significant Impact Levels for Ozone and Fine Particles in the Prevention of Significant Deterioration Permitting Program. https://www.epa.gov/sites/default/files/2018-04/documents/sils_policy_guidance_document_final_signed_4-17-18.pdf. Accessed May 2022.

Any inference in the Proposed Rule as to the significance of BRS's NOx emissions relative to downwind Ozone concentrations at Brazoria is based on a subjective reference concentration of 0.01 ppb and is inconsequential.

Figure 3: Taken from Figure A-1 of the "Screening Assessment of Potential Emissions Reductions, Air Quality Impacts, and Costs from Non-EGU Emissions Units for 2026"

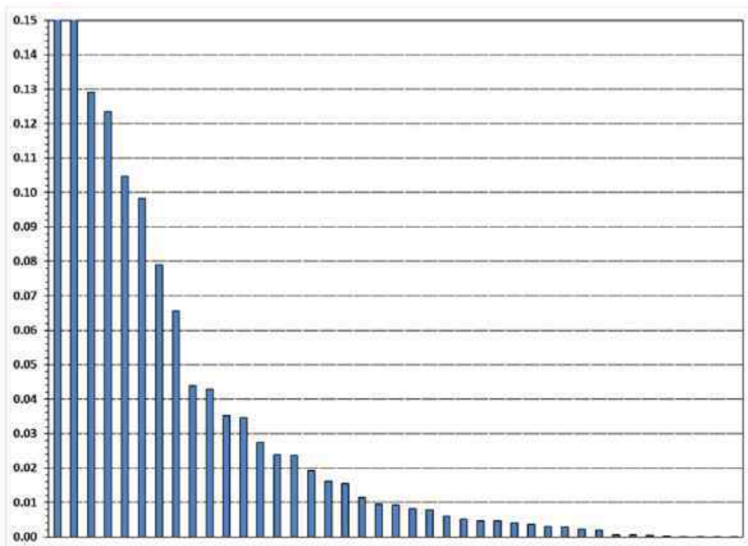

Figure A-1. Rank-ordered maximum downwind contributions from individual industries

2.5 EPA's Approach Applies Significance to BRS Without Appropriate Basis.

The CAMx model allows for the modeler to "tag" certain sources or groups of sources to determine the portion of predicted concentration at a receptor that could be attributed to that source or group of sources. In the obsolete modeling that EPA leveraged in the determination of significance, EPA did not tag individual industries, but rather only tagged 53 groups of sources, comprised predominantly of states (other tags were related to biogenic emissions, offshore emissions, international emissions, tribal emissions, and boundary condition emissions). No explicit apportionment of individual industries was performed in the modeling. Rather, as stated in Section 2.2, results of obsolete modeling were extrapolated in a rough estimate of receptor concentrations attributable to different industries. EPA then compared those extrapolated industry results to the subjective reference level of 0.01 ppb (Section 2.3).

Based on EPA's approach, only one state's steel industry is "significantly" contributing to potential ozone issues at a downwind receptor out-of-state. EPA did not readily disclose which state's steel industry was "significant" nor what downwind out-of-state receptors were impacted by that state's steel industry. EPA disclosed simply that the steel industry from one state featured maximum extrapolated concentrations above 0.01 ppb at 11 downwind receptors - see **Figure 4** which presents EPA's Table A-3 of their screening assessment[18]. The impacts from all evaluated steel industry emissions are noted with an arrow. Note that NOx emissions from one state's steel industry featured an extrapolated concentration more than 0.01 ppb.

Figure 4: Taken from Table A-3 of the "Screening Assessment of Potential Emissions Reductions, Air Quality Impacts, and Costs from Non-EGU Emissions Units for 2026"

Table A-3. Estimated Total, Maximum, and Average Contributions from Each Industry, and Number of Receptors with Contributions >= 0.01 ppb for 2023

	Maximum Contribution	# Receptors with Contributions >=0.01 ppb	Total Contribution	# States with Highest Contribution >= 0.01
Break Points	0.01 to 0.04	> 1 to 9	0.1 to 0.4	> 1 to 9
	>= 0.05	>= 10	>= 0.5	>= 10

1st Tier of Industries for Further Analysis Based on AQ Contributions
These industries (1) have a maximum contribution to any one receptor of >0.10 ppb AND (2) contribute >= 0.01 ppb to at least 10 receptors.

2nd Tier of Industries for Further Analysis Based on AQ Contributions
These industries either have:
(1) a maximum contribution to any one receptor >=0.10 ppb but contribute >=0.01 ppb to fewer than 10 receptors, or
(2) a maximum contribution <0.10 ppb but contribute >=0.01 ppb to at least 10 receptors

While the 0.01 ppb concentration threshold is not a level of significance in our opinion (Section 2.3), in **Figure 4**, EPA has found that all other state's steel industries do not "significantly" contribute to Ozone concentrations at downwind receptors. However, while EPA demonstrates that only one state's steel industry has downwind impacts of 0.01 ppb and is thus "significant", EPA applies "significance" to the steel industry in 23 states. Even though the AR steel industry and BRS specifically may have no impact on the 11 receptors identified as having extrapolated concentrations above the 0.01 ppb subjective reference level,

[18] Screening Assessment of Potential Emissions Reductions, Air Quality Impacts, and Costs from Non-EGU Emissions Units for 2026, February 28, 2022. Docket No. EPA-HQ-OAR-2021-0668

EPA has identified AR steel and thus BRS NOx emissions as significant to downwind receptors based on another state's (and thus another facility or facilities) emissions.

We applied the methodology EPA used to develop the table of industry-level significance in **Figure 4** using receptor specific calibration factors calculated at each maintenance and non-attainment receptor (except for California which was excluded from EPA's analysis). The calibration factors were calculated using the procedures outlined in EPA's "ozone_transport_policy_analysis_final_rule_tsd_0.pdf" document. The base case CAMx model results for both 2016 and 2023 and the state-specific anthropogenic NOx emission totals for 2016 and 2023 used for the calibration factor calculation were obtained from the EPA's air quality assessment tool (AQAT)[19]. Attachment 1 to this memorandum outlines our understanding of EPA's extrapolation approach.

An inventory of NOx emissions from BRS was then provided to Woodard & Curran as derived from BRS's 2021 emission inventory of actual NOx emissions of all operational units at the BRS facility that could potentially fit under any of the furnace or boiler types defined under the Proposed Rule. These 2021 actual NOx emissions are conservative relative to the NOx emissions EPA has within their unmodeled 2017gb, 2018gc, or 2019NEI inventories (see **Table 2**), but are reflective of current normal production levels. However, a 5% safety factor was added to include a measure of conservatism. These emissions were added to the EPA 2023fj NOx emission inventory characterized as within the AR Steel industry (NAICS code 331110). The extrapolated contribution of BRS to the 8-hour Ozone design value concentration at each desired maintenance and non-attainment receptor was then calculated following EPA's methodology by multiplying the total state contribution from the 2023 base case CAMx modeling result by the ratio of BRS emissions vs. total anthropogenic emissions and then by the EPA calibration factor for each receptor. **Table 3** presents the results of our analysis using EPA's methodology for EPA's 2023fj AR Steel NOx inventory, that inventory plus BRS (with conservative safety factor), and BRS's NOx emissions alone.

It should be noted, that based on our understanding of the extrapolation approach, EPA does not consider distance from a receptor within a state. The calibration factors are based on state-level apportionment data and are not capable of considering the location of an emission source within a state (see Attachment 1). For instance, a 10 ton per year NOx source at the southern border of AR (less than 450 kilometers from Brazoria) would be extrapolated for contribution at Brazoria using the same factor as a 10 ton per year NOx source at the northern border of AR (more than 900 kilometers from Brazoria), despite the fact that the northern source would contribute less at Brazoria than the southern source (see Section 3.2 for a modeling analysis highlighting the importance placed on source-receptor geography). BRS is in the northeast corner of the state, some 850 kilometers away from Brazoria while many more NOx sources are in the southern portion of AR and less than 450 kilometers from Brazoria. Thus, applying the state-wide calibration factor for BRS is highly conservative. However, even with this conservatism and the added conservatism within the emissions estimate, neither the EPA's AR Steel inventory, nor the inventory with BRS added, nor BRS

[19] EPA's "Ozone AQAT Proposal", Proposed Rule document EPA-HQ-OAR-2021-0668-0117.

alone would have an extrapolated maximum downwind impact above the 0.01 ppb subjective reference level.

BRS has a component of operations that has yet to come online but is anticipated to become active prior to the year 2026 (EPA's target year for proposed control implementation).[20] We therefore considered the additional scenario where the expanded operations were added to that of BRS, and extrapolated impacts for comparison to the 0.01 ppb subjective reference level (see **Table 3**). As noted, even with the additional NOx emissions from the expanded operations and conservative safety factors, BRS's maximum downwind impact is below the 0.01 ppb reference level.

[20] Exploratory Ventures, LLC , an affiliate of BRS, has commenced construction of a new scrap to steel products mill on a site adjacent to BRS (the "EV Facility"). The EV Facility and related NOx emissions from the emission units subject to regulation under the Proposed Rule will be similar to those of the BRS facility. I.e., the existing BRS scrap to steel mill includes two EAFs and supporting equipment, and the new EV Facility will also have two EAFs and supporting equipment. The "BRS Expansion" scenario accounts for all sources at the existing mill potentially within the definition of an emission unit covered by the Proposed Rule regardless of whether each unit has PTE below or above 100 tpy, and also accounts for the same sources at the new EV Facility.

Notes:
[1] Based on EPA 2023fj emission inventory, sum of AR annual NOx sources under NAICS code 331110 (496.25 tons)
[2] BRS annual NOx emissions (550.578 tons) taken as actuals from the most recent year of operation (2021) plus a conservative safety factor of 5%.
[3] Expansion annual NOx emissions (507.523 tons) taken as projected actuals based on current operations of existing BRS site plus a conservative safety factor of 5%.

Based on EPA's approach, which is highly conservative for BRS given its distance from Brazoria relative to other NOx sources within AR, it is clear that 1) BRS's NOX emissions do not contribute above the subjective reference level of 0.01 ppb at any downwind receptors, nor at Brazoria specifically, and 2) EPA is attributing significance to BRS NOx emissions based on extrapolated concentrations using emissions from another state and thus another facility or facilities. This is inappropriate.

Any inference in the Proposed Rule as to the significance of BRS's NOx emissions relative to downwind Ozone concentrations at Brazoria is unsupported by EPA's extrapolation methodology, is based on another state's emissions, and is inconsequential.

2.6 EPA's Modeling Has Substantial Uncertainty and Suspect Capability to Predict A 0.01 ppb Level of Significance.

Notwithstanding the discussion in previous sections of this memorandum, EPA determined that 0.01 ppb of Ozone is a "significant" threshold of contribution to downwind Ozone problems from industry (Section 2.4). In addition, EPA has determined that AR NOx emissions may impact the status of Ozone maintenance at Brazoria. Thus, the accuracy and capability of EPA's model to resolve a 0.01 ppb variation in Ozone concentration and the model's accuracy at Brazoria is critical in understanding the veracity of the estimated impact as extrapolated for the steel industry and applied to BRS at Brazoria. **Table 4** presents verification statistics of EPA's modeling relative to Brazoria[21].

Table 4: Verification Statistics of EPA's CAMx Modeling for at Brazoria (verification year 2016)

Receptor	r^2 Model vs Obs.	Standard Deviation of Model (ppb)	Correlation coefficient Model vs. Obs (r)	Root Mean Square Error of Model (ppb)	Normalized Mean Bias (ppb)
Brazoria, TX, EPA Monitor #480391004	0.37	8.13	0.61	10.61	-13.01

[21] EPA's "CAMx 2016v2 MDA8 O3 Model Performance Stats by Site.xlsx"; Proposed Rule document EPA-HQ-OAR-2021-0668-0071.

According to EPA's disclosed verification statistics, the square of the correlation coefficient (r^2) is low (0.37). r^2 is a measure of how much variation seen in the model can be explained by actual variation in observation. A r^2 of 0.37 indicates that only 37% of the variation predicted by the model at Brazoria can actually be explained by observation. In other words, the model varies significantly more at the receptor than what is seen in reality. **Figure 5** presents the standard deviation EPA calculated at Brazoria for observations during the verification year (2016) and for the model predictions of 8-hour Ozone concentrations. The model over-predicts the variation at Brazoria by more than double. This has implications for use of a threshold of 0.01 ppb and the model's capability in predicting such a relatively small variation in concentration. Given the model's significantly higher degree of variation at Brazoria, substantial false positive predictions of a 0.01 ppb concentration would be likely. The model's high level of variation is poorly connected to actual changes in Ozone concentrations in general at all receptors, and at Brazoria in specific.

The model's prediction accuracy as measured by the root mean square error (RMSE) statistic at Brazoria (10.61 ppb) is generally average (at the 55th percentile) among other receptors (see **Figure 6**). This indicates that the model's capability at Brazoria is generally average relative to the model's accuracy across all the receptors but is still relatively high at over 10 ppb. This level of inaccuracy (10 ppb) is over 1,000 times greater than the threshold of significance that EPA is leveraging the model for at Brazoria (0.01 ppb). For many other receptors, the inaccuracy is higher, up to over 24 ppb in RMSE, an error 2,400 times greater than the threshold EPA is applying the model against.

Figure 5: EPA Calculated Standard Deviation (SD) of Observations and Model Predictions at All Receptors

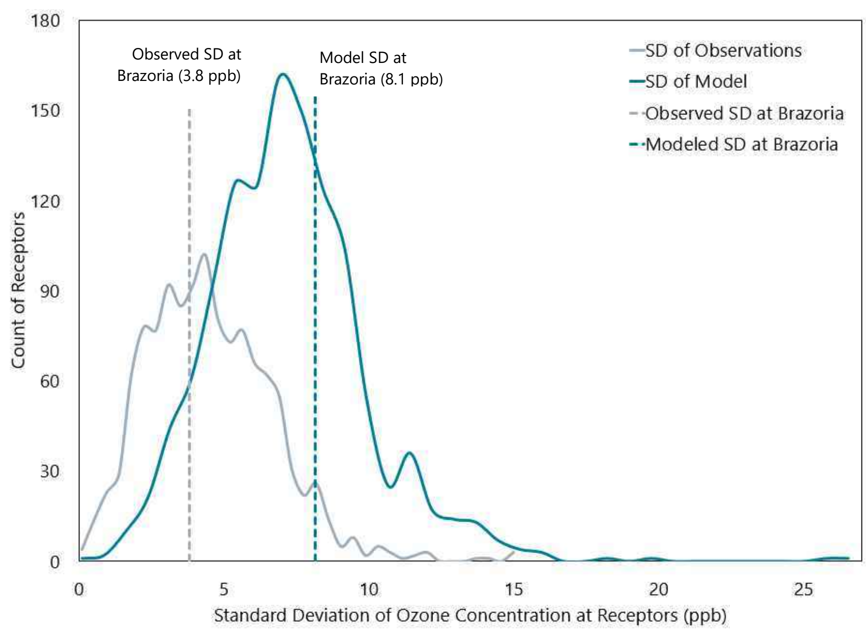

Figure 6: Model Root Mean Square Error at All Receptors vs Brazoria

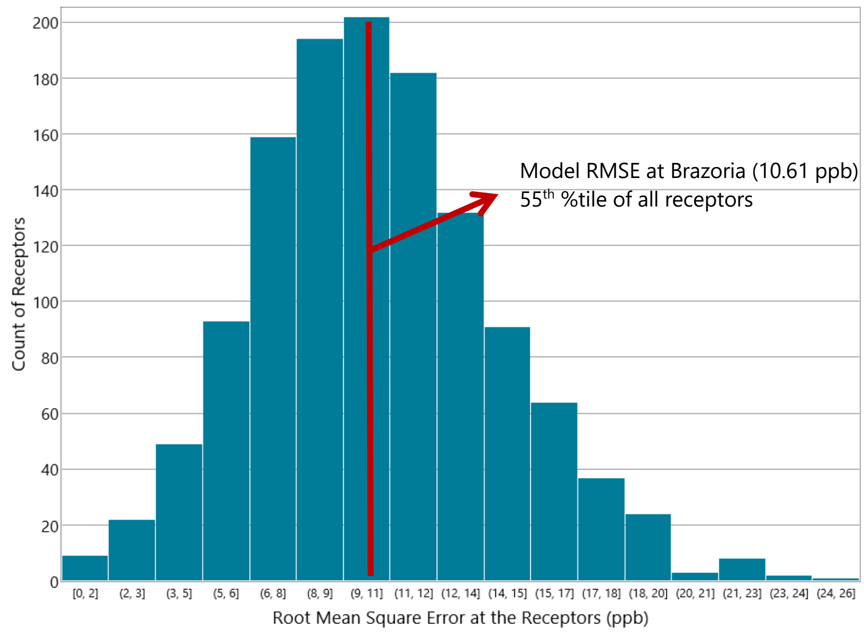

Most receptors (54%) are below what literature has found to be a minimum threshold of model-to-observation correlation skill (r=0.5) for photochemical grid models like CAMx[22]. This is an important deficiency since, as discussed in Section 2.5, significance of BRS's NOx emissions at Brazoria is based on model results of other emissions at other receptors. EPA has applied significance to the steel industry based on extrapolations of one state's modeled impacts at multiple receptors (see Section 2.5). Thus, considering the broad multi-receptor application of modeling results employed by EPA, the majority of receptors being below the literature's minimum correlation threshold, would attach deficiency to the majority of the model's results, including the extrapolation applied to results at Brazoria. Further, a vast majority of receptors (81%) are below what literature considers the threshold of "very good" capability of photochemical grid models (r=0.75; see **Figure 7**).

Many receptors (31%) are outside of what literature has found to be a minimum window of model bias (normalized mean bias, NMB = <+/-15%). A vast majority of receptors (79%) are outside the window of a good photochemical grid model (NMB=+/-5%), meaning the model has substantially more model bias than typically seen in the more skilled model configurations verified. The model's bias at Brazoria (NMB=-13.01

[22] Emery et al (2017). Recommendations on statistics and benchmarks to assess photochemical model performance. Journal of A&WMA. https://www.tandfonline.com/doi/full/10.1080/10962247.2016.1265027; accessed May 2022.

ppb) is nearly at the minimum threshold of skill considered in literature and is well outside the bias window of a what literature considers a "very good" performing photochemical model (see **Figure 8**).

These verification statistics lead us to the opinion that the EPA model is largely incapable of the level of accuracy and consistency that would support applying a threshold of significance of 0.01 ppb to the model's results at Brazoria and at a majority of other receptors. The model would not reliably be able to predict whether or not BRS's NOx emissions would actually contribute 0.01 ppb and thus "significance" at this level based on the model would not be reliable.

Figure 7: Model-Observation Correlation Coefficients at All Receptors vs. Brazoria

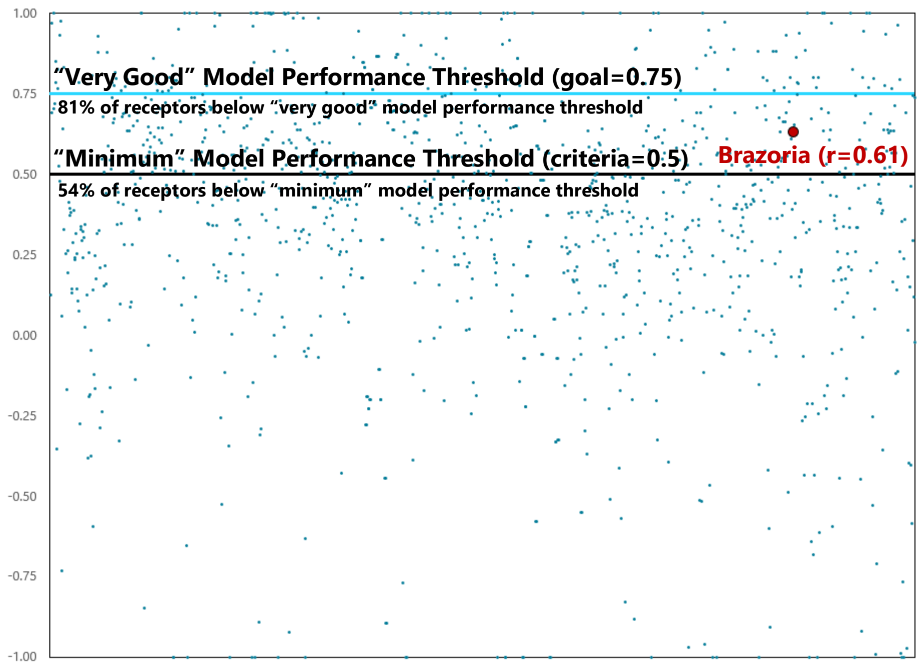

Figure 8: Normalized Mean Bias at All Receptors vs. Brazoria

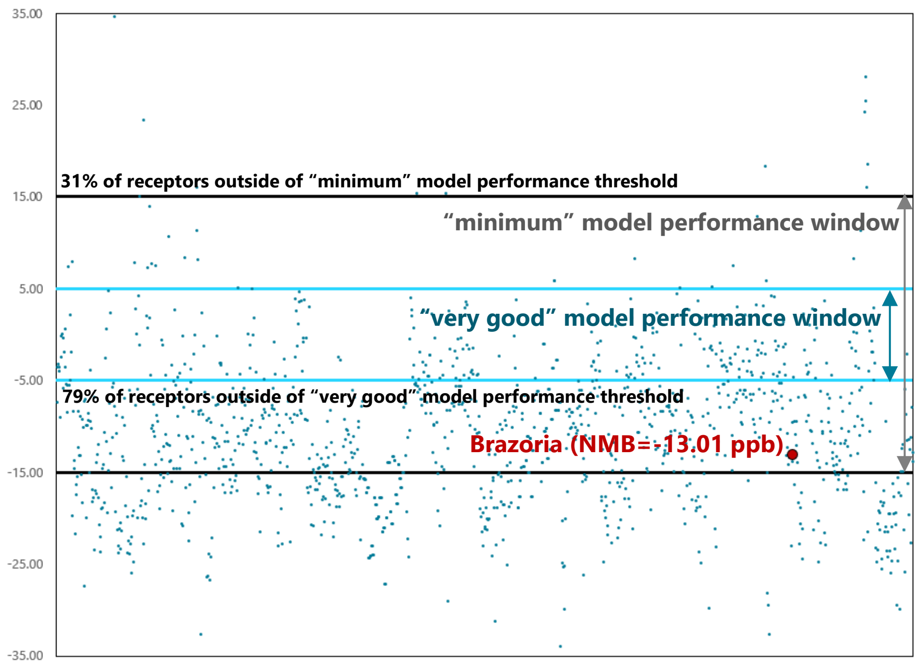

In addition to the statistical model uncertainty and capability, review of data provided by EPA uncovered several inconsistencies that would contribute to a general uncertainty in results and a gap in ability to make precise determinations of significance of (in general) the steel industry's or (specifically) BRS's NOx emissions. For instance, based on the contents of several "readme" files which appear to be exchanges between EPA modelers, multiple versions of CAMx data were referenced, implying use of data associated with multiple versions of the model (v6.50, v7.0beta6, v7.00, and v7.10)[23]. If multiple versions of CAMx were used and/or inputs, outputs, or tools designed for different versions of CAMx were leveraged, the modeling assessment would be inconsistent and results largely irrelevant. In another exchange among the modelers[24], it was noted that model outputs were copied and handled over multiple operating systems and that numerical noise in model outputs could be present and could contribute to variations in modeled concentrations. If that noise was on the order of a level of EPA's reference level of 0.01 ppb, any implications based on the modeling would be irrelevant.

[23] Readme files from data provided by EPA on external hard drive.
[24] Readme file from /work/ROMO/2016platform/CAMx_v7.10/2026fj_nonegusa_16j/12US2/postp_tools/makefinaltable/log/, as provided by EPA on external hard drive.

Any inference in the Proposed Rule as to the significance of BRS's NOx emissions relative to downwind Ozone concentrations at Brazoria is based on modeling that is largely incapable of predicting Brazoria Ozone variability, includes uncertainty from file management and model version issues, and is inconsequential.

3. ADDITIONAL MODELING DATA AND THE SIGNIFICANCE OF BRS

3.1 Air Parcel Trajectories Using HYSPLIT Have Been Historically and Recently Approved by EPA in Determination of Cross-State Ozone Transport Significance and Were Used in The Proposed Rule by EPA in Screening Assessments.

The National Oceanic and Atmospheric Administration (NOAA) Air Resources Laboratory's (ARL) Hybrid Single-Particle Lagrangian Integrated Trajectory model (HYSPLIT) is designed to evaluate air parcel trajectories, complex dispersion, and deposition simulations. HYSPLIT has evolved over more than 30 years and is one of the most extensively used atmospheric transport and dispersion models in the atmospheric sciences community.[25] HYSPLIT has been applied by regulatory agencies to perform back-trajectory analyses to evaluate the origin of air masses and establish source-receptor relationships. The EPA has recently relied on the State of Maine's HYSPLIT back-trajectory analyses, in conjunction with photochemical grid modeling, to approve Maine's request to remove a portion of the state from the Ozone Transport Region (OTR).[26] In addition, EPA used HYSPLIT trajectory modeling extensively in the Proposed Rule to evaluate Environmental Justice concerns related to coal-fired EGUs and perform screening assessments of emissions sources. Thus, HYSPLIT is a reputable and applicable model to screen long-range transport impacts, and EPA has shown this to be the case by approving its use as such in the past as well as using HYSPLIT in the Proposed Rule themselves. Were BRS to be a significant contributor to Ozone concentrations at Brazoria, HYSPLIT modeling would substantively corroborate EPA's extrapolations. If little corroboration exists, the finding of significance from EPA's extrapolations would be unsupported.

3.2 Based on Back-Trajectory Modeling, BRS Would Not Significantly Contribute to 2026 Maximum Ozone Events at Brazoria.

HYSPLIT was utilized to calculate seventy-two hour back-trajectories for the EPA's top-ten CAMx predicted maximum daily 8-hour (MDA8) 2026 ozone events for Brazoria as summarized in **Table 5**.

Brazoria, TX, EPA Monitor #480391004	69.1	71.2	6	30	63.3
			6	6	61.6
			5	20	60.7
			6	8	59.8
			9	28	59.2
			9	11	58.2
			9	29	57.0
			5	18	56.6
			5	17	56.0
			5	6	55.8

Each HYSPLIT back-trajectory examined four starting heights above ground: 100-meters, 500-meters, 1000-meters, and 1500-meters. These heights include the expected levels within the atmospheric mixing layer, yet above the influence of local terrain, which EPA considers relevant in assessing the transport of air parcels for potential contributions to ozone concentrations at monitor locations.[27] Meteorological data files for the analysis were obtained from the NOAA ARL archive[28] and consist of the National Centers for Environmental Prediction (NCEP) North America Mesoscale (NAM) daily meteorological files, at a 12-km horizontal resolution. The start time for each back-trajectory analysis was set equal to the assumed starting hour of the predicted maximum eight-hour ozone value for each elevated ozone day, converted to Universal Time (+ 6 hours).

The results of the back-trajectory analyses indicated that the top three ozone days with greater than 60 ppb Ozone (highlighted in **Table 4**) had contributing air parcels originating well outside of, or only briefly passing through the very southern section of AR, as shown in **Figure 9** (> 60 ppb trajectories coded orange in the bottom map). For the remaining 7 days, a majority of the parcels also originated outside of AR (< 60

[27] EPA's *Responses to Significant Comments on the State and Tribal Designation Recommendations for the 2015 Ozone National Ambient Air Quality Standards (NAAQS)*, Docket Number EPA-HQ-OAR-2017-0548, April 2018.

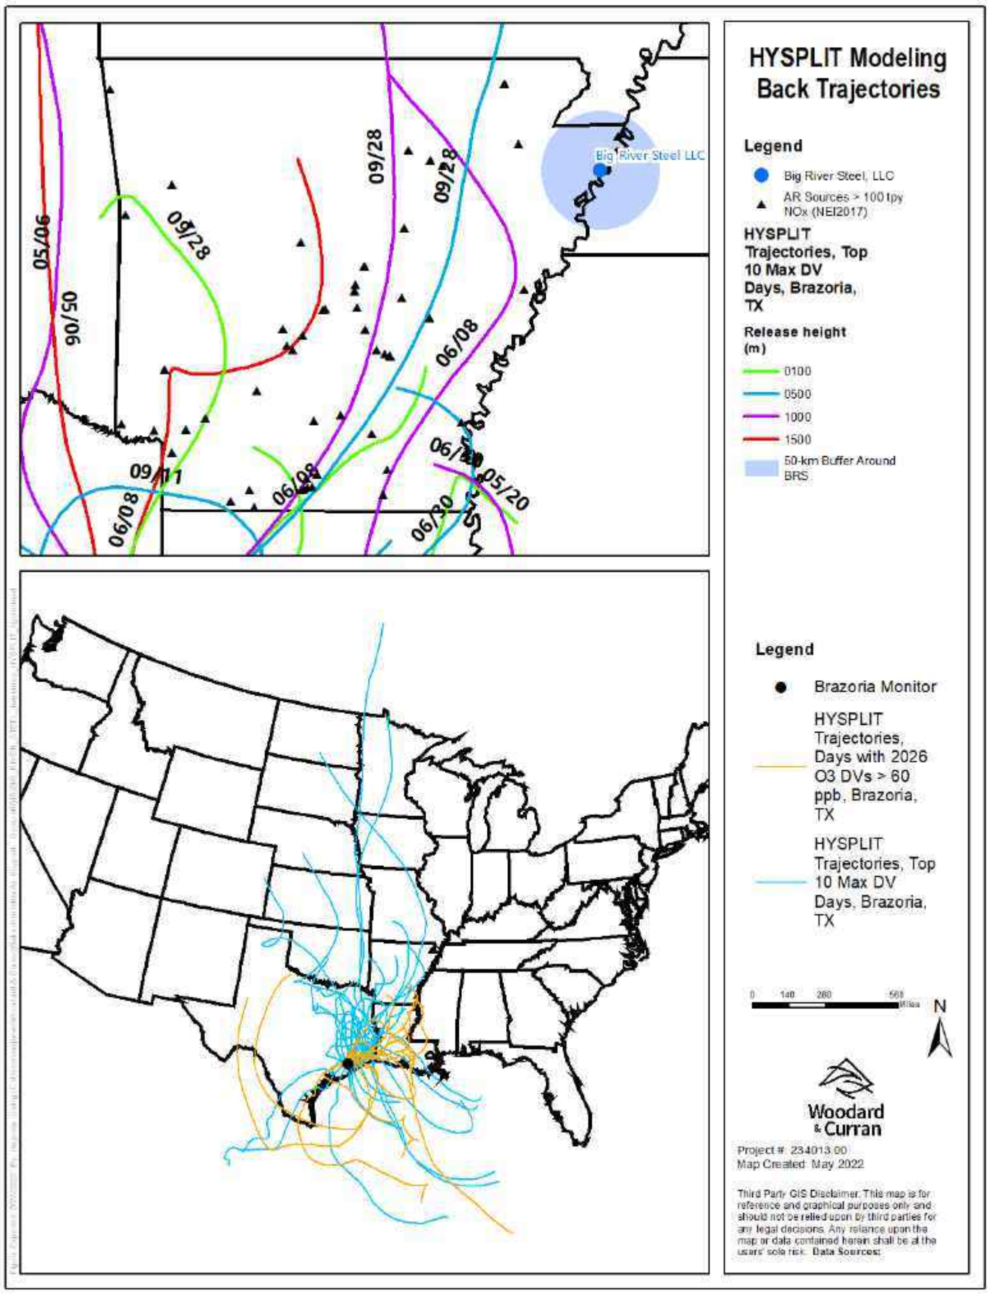
ppb trajectories coded blue in the bottom map of **Figure 9**). For the parcels that did traverse through the state, the majority traveled through the central third of the state, and no parcel traveled within even 50 kilometers of BRS.

While back-trajectories offer a general assessment of source–receptor relationships and turbulent mixing processes can impact air parcels during transport, HYSPLIT back-trajectory analyses have utilized meteorological data at an equivalent horizontal resolution to EPA's CAMx modeling (12-km) and EPA has relied on HYSPLIT data to support other cross-state Ozone transport determinations. At the least, if BRS was significantly contributing to maximum Ozone events at Brazoria, HYSPLIT back-trajectory modeling should corroborate that finding of significance by multiple trajectories at multiple starting heights being near BRS. The additional modeling indicates that this is not the case. Additional modeling suggests that when Ozone events are maximum at Brazoria (e.g., > 60 ppb), parcels typically do not originate in AR in general. The HYSPLIT modeling suggests that when metrological flow in the region is such that NOx emissions in the northern portion of AR may contribute to Ozone concentration at Brazoria, those contributions are a portion of an overall concentration that is well below the 8-hour NAAQS (< 60 ppb) and thus would pose no significant threat to Brazoria attaining or maintaining the 8-hour Ozone NAAQS of 70 ppb. To the extent that any sources of NOx emissions in AR contribute significantly to Brazoria Ozone concentrations, those sources would be in the central and southern areas of AR, and not in the distant northeastern area where BRS is located. This additional modeling straightforwardly refutes the broadly determined finding of significance that EPA has placed on BRS's NOx emissions relative to Brazoria Ozone concentrations.

Any inference in the Proposed Rule as to the significance of BRS's NOx emissions relative to downwind Ozone concentrations at Brazoria is unsupported and uncorroborated by additional modeling and is inconsequential.

Figure 9: HYSPLIT Centerline Trajectories of Top Ten Max Daily 8-hour Ozone Design Values (2026) for Brazoria, TX

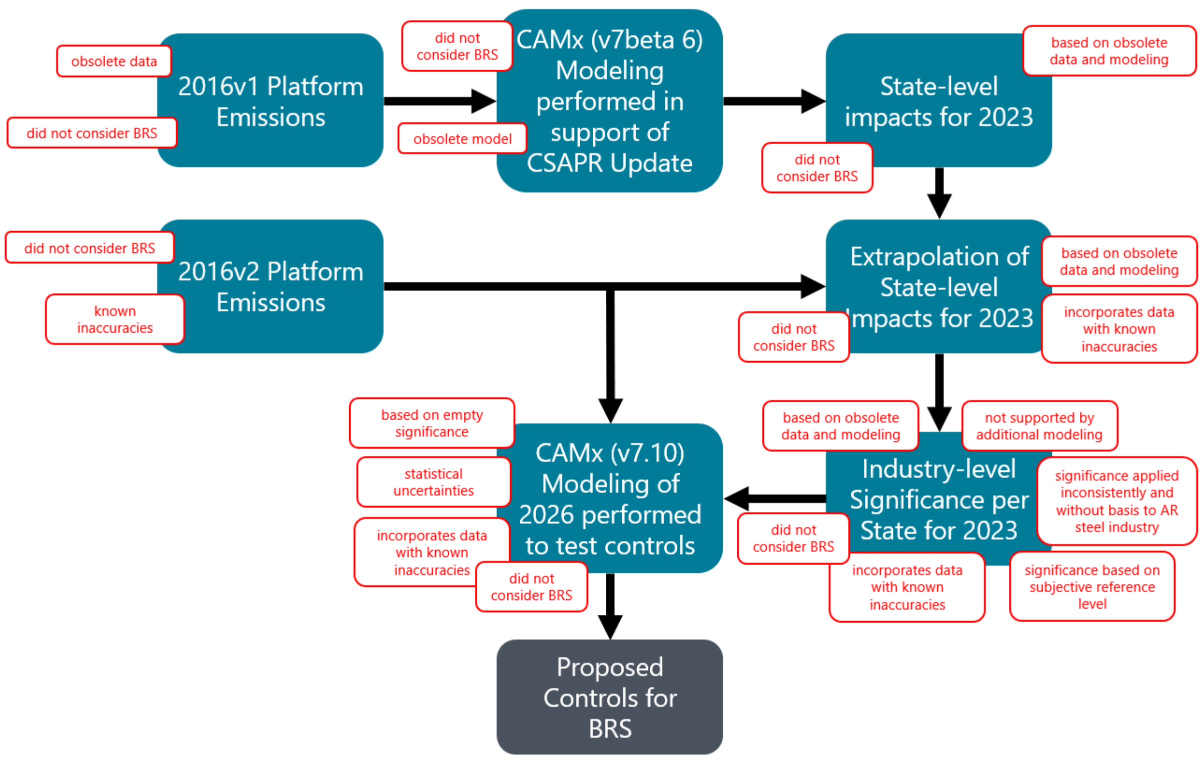


The authors gratefully acknowledge the NOAA Air Resources Laboratory (ARL) for the provision of the HYSPLIT transport and dispersion model and/or READY website (https://www.ready.noaa.gov) used in this memo.

4. CONCLUSION

Reiterating the schematic describing EPA's approach in **Figure 1** and updating with commentary resultant from the above discussion provides a representation of our findings and opinions (see **Figure 10**). At each step in the process that EPA applied, uncertainties and gaps of appropriateness and robustness were introduced. Based on our review and analysis, it is our opinion that _EPA's modeling in support of the Proposed Rule does not sufficiently demonstrate that NOx emissions from BRS significantly contribute to Ozone concentrations at the monitor in Brazoria County, Texas_.

Figure 10: Estimated Schematic of EPA's Approach to Determine Industry-level Significance – With Commentary



ATTACHMENT 1: UNDERSTANDING OF EPA'S EXTRAPOLATION APPROACH

Our understanding of EPA's extrapolation approach employed in the Proposed Rule to determine the contribution of a given amount of NOx emissions (E) is summarized below as a factor (f) which scales state-level model contributions (C) at a given receptor (R), multiplied by the emissions.

The contribution (C) of emissions, E, to Ozone concentrations at receptor, R can be expressed as Equation 1, where $C_{S,R}^{2023}$ is the state contribution at receptor R, for the 2023 inventory year.

$$C_{E,R} = E f_R C_{S,R}^{2023} \qquad \text{(Eq. 1)}$$

The receptor-level calibration factor in Eq. 1, f_R, is calculated as a ratio of changes in modeled contributions at receptor, R (Eq. 2). The ratio is a linear assumption to estimate how contributions at R would respond to emissions non-linearly due to model dynamics. The ratio compares how the model actually responds to emissions (the numerator in Eq. 2 – the difference between two modeled concentrations at R, year 2023 versus 2016) versus how the model would have responded to an increase in emissions (the denominator in Eq. 2 – the difference between a 2023 modeled concentration at R and a derived concentration at R for year 2016) if the modeled response to a change in emissions were linear.

$$f_R = \frac{C_R^{2016} - C_R^{2023}}{C_R^{2016*} - C_R^{2023}} \qquad \text{(Eq. 2)}$$

The derived 2016 concentration term in the denominator of Eq. 2 is EPA's "uncalibrated" concentration, C, at receptor, R = C_R^{2016*}. This term approximates what the concentration at R would be if the modeled concentration at R for year 2023 were adjusted upwards based on how much more emissions were present in 2016 relative to 2023 in each state. The uncalibrated "2016" concentration at R is the modeled 2023 concentration plus the sum of each state's uncalibrated concentration change at R.

$$C_R^{2016*} = C_R^{2023} + \textstyle\sum_S dC_{S,R}^{2016*} \qquad \text{(Eq. 3)}$$

The uncalibrated contribution change from state, S, at receptor, R = $dC_{S,R}^{2016*}$ is the result of scaling the modeled 2023 contribution from state S at receptor R by the fractional change in emissions within that state.

$$dC_{S,R}^{2016*} = C_{S,R}^{2023}\left(\frac{E_S^{2016} - E_S^{2023}}{E_S^{2023}}\right) \qquad \text{(Eq. 4)}$$

Where state-level emissions in state, S, for inventory year, Y = E_S^Y and the contribution of state, S, at receptor, R, for model year Y = $C_{S,R}^Y$.

In summary, EPA estimated the model response due to emissions changes of a complex multi-dimensional non-linear chemical transport model at a given receptor (R) by the algebraic application of linear factors (dC and f_R) to a state-level modeled contribution there ($C_{S,R}^{2023}$).

Subject: Technical Feasibility of SCRs on Big River Steel's Electric Arc Furnaces

Introduction

The EPA has proposed new performance standards for electric arc furnaces (EAF) in the steel industry, issued on April 6, 2022, with a review and comment period to follow. The proposed rules are part of a proposed Federal Implementation Plan (FIP), issued under the "good neighbor" provisions of the Clean Air Act (CAA), which would establish new emission limits for multiple sources in order to limit the emissions of NO_X from states that significantly affect the ability of other downwind states to comply with the Ozone National Ambient Air Quality Standards (NAAQS). Per proposed 40 CFR 52.43(c), EAFs will be required to meet a NO_X emission limit of 0.15 lbm/ton steel on a 3-hour rolling average. The EPA based this limit on their consideration of baseline emissions and permit limits between 0.2 and 0.35 lbm/ton steel, and a minimum 40 percent reduction in NO_X emissions was assumed by adding a selective catalytic reduction (SCR) system on EAFs. Facilities are to meet these emission limits by the start of the ozone season (May 1) in 2026.

Big River Steel owns and operates a steel facility in Osceola, Arkansas, which includes two EAFs. An EAF is a metallurgical furnace that uses graphite electrodes to supply electrical energy. First, the furnace is charged with scrap metal, with the composition of the scrap metal based on the steel that is to be made. The electric energy will generate electric arcs in the furnace that melt the steel, and after melting is complete, the molten steel is refined to remove various impurities (e.g., phosphorous, sulfur, aluminum, silicon, manganese, etc.) by blowing oxygen through the molten steel. The system is operated as a batch process, alternating between melting, refining, and other steps such as de-slagging (tilting the furnace to pour slag through an opening), tapping (pouring the molten steel from the furnace), and turn-around (re-charging the furnace for the next batch of scrap metal). Therefore, the flue gas properties will vary significantly depending upon its stage of operations, making NO_X controls for EAFs difficult to implement.

The EAFs are the largest NO_X emitters at the facility (the only emission units permitted to emit more than 100 tons of NO_X per year) and produces other regulated emissions as well. Particulate matter is controlled by using a baghouse downstream of each EAF, which removes the particulate matter before exiting that baghouse's stack. Prior to entering the baghouse, the flue gas is cooled, because the flue gas temperatures from the EAF are beyond the operating temperature of all bags in regular commercial use. Prior to the baghouse, the cooled flue gas also goes through a spark arrestor to remove larger metal sparks and flammable debris that could otherwise compromise the baghouse. The proposed ruling by the EPA impacts the current EAFs, as well as a planned second facility which started construction earlier this year and will also include two EAFs.

Current Emissions

Big River Steel conducts routine stack tests on the emissions from their EAF, and over the last several years, NO_X emissions have averaged around 6.7 ppm, with a maximum recorded value of 12.6 in 2021 and a lowest recorded value of 4.7 in 2019. Converting the emissions to lbm/ton of steel, the NO_X emission average was about 0.20 lbm/ton, with a high of about 0.29 lbm/ton and low of 0.15 lbm/ton. These emission tests were hour-long tests, with an average value derived from three tests. Based on the average values, the emissions from the EAF would need to be reduced by 23 percent, and based on the maximum test value, the reduction would need to be near 49 percent. Since the emissions cannot be surpassed, reduction technologies like an SCR would need to remove sufficient NO_x from the maximum emissions to a margin below the limit, and 49 percent would be the minimum removal efficiency required.

Selective Catalytic Reduction

Technical Background
SCR systems are a post-combustion NO_X control technology for achieving reductions in NO_X emissions which have been primarily utilized in utility coal boilers. In SCR systems, vaporized ammonia (NH_3) is injected into the flue gas stream, acting as a reducing agent, with a set of one to four (typ.) catalyst banks helping to facilitate the reaction. Some utility boiler SCR installations have been able to lower NO_X emissions by greater than 90 percent, but this is contingent on the unit's operating characteristics, such as flue gas and fly ash composition, as well as the fuel that is being burned.

The primary chemical reactions between NO_X and NH_3 are demonstrated by the following equations:

$$2NO + 2NH_3 + \frac{1}{2}O_2 \rightarrow 2N_2 + 3H_2O$$

$$N0_2 + 2NH_3 + \frac{1}{2}O_2 \rightarrow \frac{3}{2}N_2 + 3H_2O$$

$$NO + N0_2 + 2NH_3 \rightarrow 2N_2 + 3H_2O$$

The reactions shown above can occur spontaneously at temperatures above 1600 °F, but at lower temperatures these reactions need a catalyst to promote their reactions. Temperatures are still an important consideration even with SCRs, as most SCRs operate in a temperature range of 550 to 900 °F. There have been catalysts installed at lower and higher temperatures; however, there are critical design conditions that a flue gas must meet in order for such a catalyst to work effectively and with consistent performance. At low temperatures, the presence of sulfur and other chemicals can poison the catalyst (permanently rendering it less effective or even ineffective), and temperatures will still need to be maintained above a minimum of approximately 400 °F. At higher temperatures (up to 1,000 to 1,100 °F), stainless steels, titanium, or other expensive materials are needed to withstand the higher temperatures, and higher volumes would be required to achieve similar NO_X reduction rates. NH_3 also will oxidize to NO_X at higher temperatures, so ammonia slip (unreacted ammonia emissions) will need to be tightly controlled to prevent unintentional NO_X production.

The reaction mechanisms between NO_X and NH_3 are very efficient, with a reagent stoichiometry of approximately 1.05 (molar ratio of NH_3/NO_X removed). A simplified schematic diagram of a typical SCR reactor for the utility industry is illustrated in Figure 1. However, due to increasingly stringent NO_X emissions regulations most modern SCR systems are built without bypass systems. SCR cleaning on modern systems is typically done by sonic horns, rather than steam or air sootblowers.

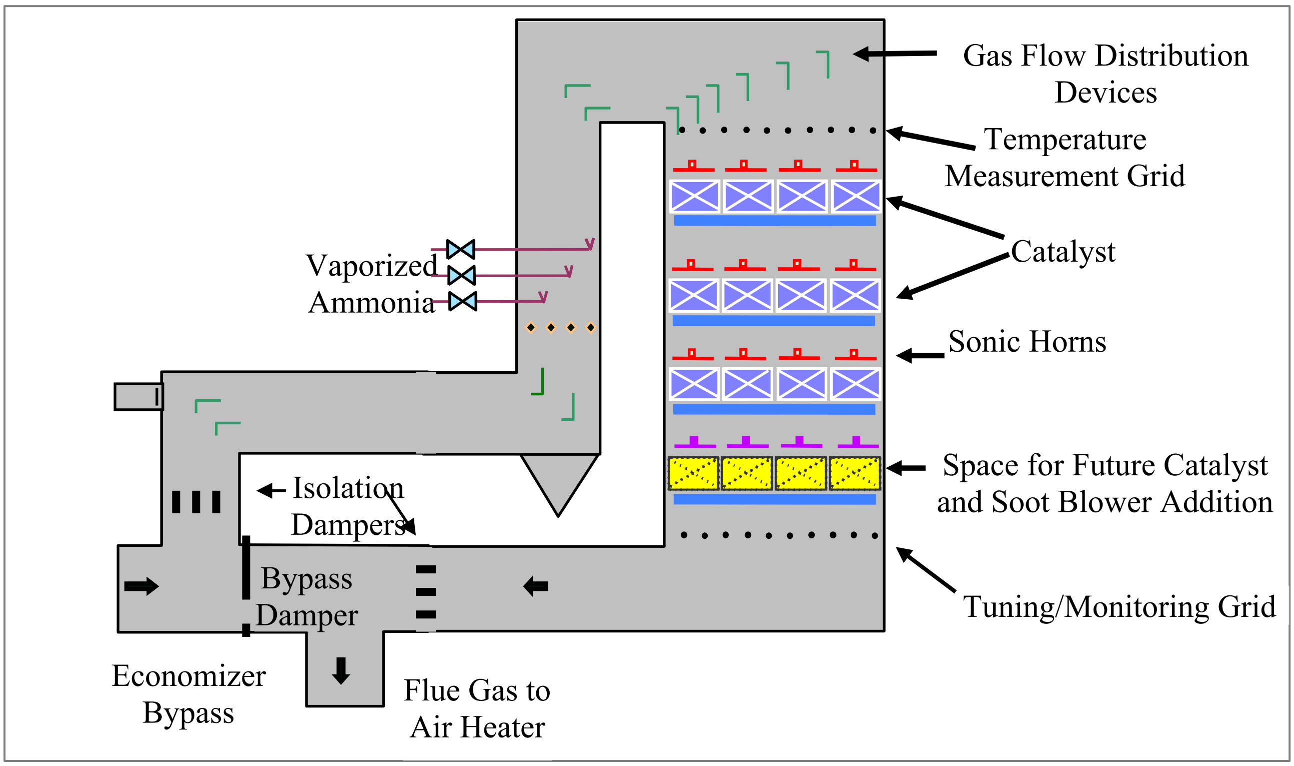

Figure 1 ***Schematic Diagram of Typical Utility Industry SCR Reactor***

The SCR reactor is the housing for the catalyst and is essentially a widened section of ductwork modified by the addition of gas flow distribution devices (turning vanes and dampers), steel grating to catch over-sized particulates, the catalyst and its support structures, access doors, and soot blowers. An ammonia injection grid is located upstream of the SCR reactor. The ammonia reagent for the SCR systems can be supplied by anhydrous ammonia, aqueous ammonia, or by conversion of urea to ammonia. Since the ammonia is vaporized prior to contact with the catalyst, the selection of ammonia type does not influence the catalyst performance. However, the selection of ammonia type does affect all other subsystem components, including reagent storage, vaporization, injection control, and balance-of-plant requirements (including potential use of auxiliary power and/or process steam in many systems).

SCR systems have a variety of interfacing system requirements to support operations. These impacts predominately relate to the flue gas draft, auxiliary power, gas temperature, controls, ductwork, and reactor footprint. Depending upon the arrangement and performance requirements, flue gas draft losses can range from 4 to 10 in. w.g. This can be compensated with the addition of induced draft (ID) booster fans. Draft losses may influence the selection and design of the ductwork, and as a result, possible structural reinforcements may need to be considered. In conjunction with fan additions or modifications, an upgrade of the auxiliary power system might be necessary, which might also be triggered by ammonia supply system requirements.

Technical Infeasibility for Deployment of SCR Systems with EAFs
The EPA has used the term "technical feasibility" in multiple proposed and promulgated rulings. This term has required clarity over the years, as it is critical to determining whether a control technology is to be implemented at a particular facility. An example of when the EPA defined this term was in the proposed ruling for "State Implementation Plans; General Preamble for the Implementation of Title I of the Clean Air Act Amendments of 1990; Supplemental," (proposed April 28, 1992) where "Technological Feasibility was discussed. In Appendix C4 of the proposed ruling, the feasibility of a technology, "should consider the source's process and operating procedures, raw materials, physical plant layout, and any other environmental impacts…"

Technical feasibility is further defined in other promulgated rulings. Drawing from the best available retrofit technology (BART) guidelines (40 CFR Part 51, Appendix Y, Section IV.D.2) as general guidance, this entails determining whether technical difficulties would preclude the successful use of the control option on the emitting unit under review based on physical, chemical, or engineering principles. As described in 40 CFR Part 51, Appendix Y, Section IV.D.2.:

> "Control technologies are technically feasible if either (1) they have been installed and operated successfully for the type of source under review under similar conditions, or (2) the technology could be applied to the source under review. Two key concepts are important in determining whether a technology could be applied: 'availability' and 'applicability.'… a technology is considered 'available' if the source owner may obtain it through commercial channels, or it is otherwise available within the common sense meaning of the term. An available technology is 'applicable' if it can reasonably be installed and operated on the source type under consideration."

The EPA "does not expect a source owner to conduct extended trials to learn how to apply a technology on a totally new and dissimilar source type. Consequently, you would not consider technologies in the pilot scale testing stages of development as 'available' for purposes of BART review." (40 CFR Part 51, Appendix Y, Section IV.D.2.2)

Based on these definitions of technical feasibility, installing an SCR after Big River Steel's EAF as it currently exists (i.e., no modifications to the process) is technically infeasible. The reasons for this determination are as follows:

1) Black & Veatch and Big River Steel are not aware of an SCR that has been installed at another EAF (e.g., Black & Veatch has not worked on an SCR project on an EAF, and Black & Veatch's and Big River Steel's research did not unearth any SCR installations on EAFs). Black & Veatch has contacted Andritz, a leading SCR provider, and they have stated they do not have an SCR installed on any EAFs. Andritz has acquired Alstom/GE's air quality control business, so their statement includes Alstom/GE's experience.

2) To the EPA's statement regarding whether a "technology could be applied to the source under review," an SCR could not be currently installed at Big River Steel's EAF because of catalyst limitations with flue gas temperatures. Black & Veatch contacted catalyst suppliers, and two (CERAM and Cormetech) have responded that they do not have any catalysts installed at the temperature ranges present at Big River Steel (other contacted vendors have not responded at this juncture). The EAF's flue gas temperatures fluctuate significantly depending on its mode of operation, with a maximum flue gas temperature greater than 1,200 °F prior to the baghouse (which is subsequently cooled to near 200 °F in order to protect the bags). Neither temperature range fits the design requirements of existing SCR catalysts.

   Black & Veatch has also conducted a literature search for low-temperature catalysts, and none could be found that operate at the temperatures found at Big River Steel's EAF. Even if one were found, it would need to be proven at an industrial scale to be considered applicable for Big River Steel. The lack of findings from the literature review corroborates Black & Veatch's discussions with vendors.

<u>Required Modifications to Install an SCR</u>
The finding that it is not technically feasible to employ an SCR at Big River Steel is further supported by the substantial modifications that would be necessary to attempt to address the flue gas temperature and composition concerns, something that (as discussed above) has not to our knowledge been accomplished anywhere in the world.

Should such an installation be attempted, there are many changes required in order to allow successful, consistent, and reliable operation at the EAF. These include changes related to the flue gas temperatures from the EAF, as well as other possible changes

Flue Gas Cooling
Flue gas cooling is currently being done at site. The flue gas is sprayed with water prior to the spark arrestors, which are located upstream of the baghouse. The flue gas is cooled to protect the bags from burning upon processing the EAF's hot flue gas temperatures. However, the spray water cools the flue gas to around 200 °F in order to protect the bags in the baghouse, which is much too low for an SCR to operate. Low-temperature catalysts also cannot be installed in flue gas streams with sulfur and other potential poisons, and installing an SCR upstream of the baghouse exposes the SCR to all of the particulate matter from the EAF. The particulate matter from the EAF has a high level of sodium and potassium, both of which are known to be harmful to catalysts. As a result, there are serious concerns with the feasibility of installing an SCR, needless to say a low-temperature catalyst, upstream of the baghouse.

Cooling the flue gas between the EAF and the existing cooling system was also investigated, despite the potential hurdles with the particulate matter content of the flue gas. The temperature profile leaving the EAF is shown in Figure 2. The data is from February 1, 2022, but it is typical of most operating days at the facility. The temperatures reach a maximum of 1,298 °F, so a cooling system will need to lower the flue gas temperature from 1,200-1,300 °F down to 550°F.

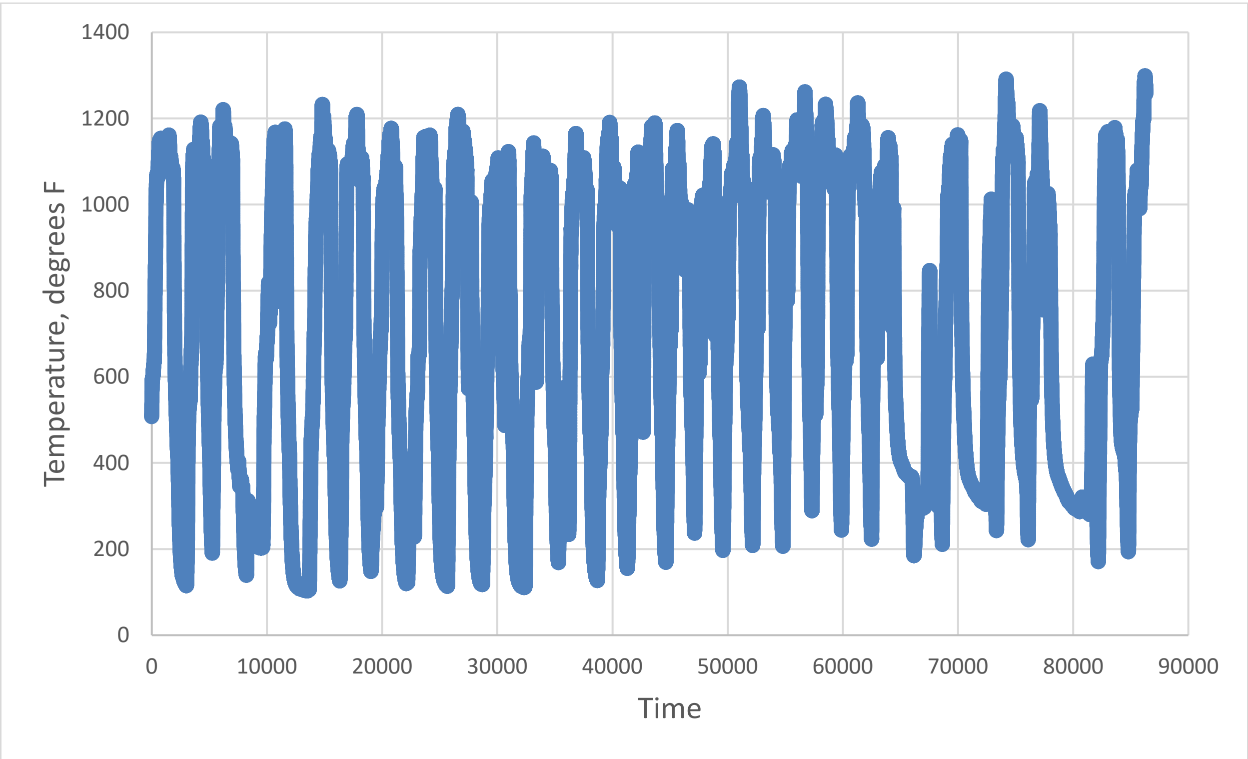

Figure 2 ***Temperature of Flue Gas Exiting EAF and Upstream of Spray Water Cooling***

Figure 2 also shows that the temperature significantly swings throughout the day, which is sensible based on the EAF's batch operations. These temperature swings present a potential problem with installing an SCR upstream of the baghouse, as the SCR catalyst and housing need to be at the necessary operating temperatures along with the flue gas. If the SCR catalyst is lower than the minimum temperature of the SCR, then de-NO_X reactions would occur at a much lower rate, if at all, even if the flue gas is well above the minimum temperature. In most SCR installations (steady state processes, not batch), there is a period of time (e.g., startup) where the SCR will warm up to the necessary temperature. If an SCR were to be installed upstream of the baghouse, then barring extensive insulation or some other method of heat retention or pre-heating with external heat sources, it's possible that the SCR steel and catalyst will cool down below the minimum temperatures between the temperature peaks. A more thorough analysis (e.g., thermal model of a potential SCR on the EAF, bench/pilot scale testing of how quickly an SCR picks up and dissipates heat, literature research on available data on the topic, etc.) is required to determine how the SCR's temperature will behave with such large variations in the flue gas temperatures, whether such reactions may prevent the SCR de-NOx reactions from occurring at a sufficient rate above that needed to comply with the 49% control efficiency required based on the above estimates, and if needed, what mitigating steps are required, and whether any such mitigating steps are feasible. This question of how the catalyst design and steel will be impacted by the temperature swings of the EAF would require a detailed engineering study that was not possible to complete during the 2.5 month comment period in this rulemaking.

Beyond simply the issue with the oscillating flue gas temperatures, cooling flue gas from 1,200-1,300 °F can typically be accomplished by two readily available methods. The first is using ambient air to temper the flue gas temperature. In this option, ambient air is drawn through filters by a blower and sent into the ductwork to mix with the flue gas and lower its temperature. This has been implemented in many combustion turbine (CT) installations that were required to have an SCR. CT exhaust temperatures are commonly around 1,000 °F and above, so tempering air has been used to lower the temperature down to around 900 °F or lower (the EAF will require more tempering air due to needing to lower flue gas temperatures by a greater degree). This additional volume of tempering air must pass through the existing baghouse, ID fan, and stack. The sizing of each of these components would need to be reviewed to ensure sufficient capacity is available (e.g., whether the ID fan support the additional pressure drop created by the SCR and the additional tempering air passing through the ductwork and baghouse); otherwise, modifications to these systems would be needed. This question, too, would require a detailed facility-specific engineering study that was not possible to complete during the 2.5 month comment period in this rulemaking.

The second option is to inject water into the flue gas, whereby the latent heat of evaporation of the water will absorb heat away from the flue gas. This process is already done at site, but since the target temperature for cooling the flue gas for the SCR is different than for protecting the bags, the existing system cannot be used for both purposes. As a result, two separate flue gas cooling systems would be required, which would not only require increased complexity, but it would require sufficient space for the residence time required for evaporation of the water vapor. This would require additional installation space, which currently does not exist.

Flue Gas Heating
Multiple options are possible for heating the flue gas from 200 °F to 550 °F downstream of the baghouse. One is to use a natural-gas fired duct burner. Duct burners have been installed in numerous facilities for increasing flue gas temperatures, most notably before heat recovery steam generators (HRSG). Utilizing natural gas combustion to heat the flue gas also introduces an additional emissions source (particularly of NO_x), which must be addressed in the facility air permit and may trigger additional permitting reviews. The flue gas temperature can also be increased by using electric or steam coils. This also would require detailed facility specific engineering not possible to complete during the 2.5 month comment period in this rulemaking.

Babcock Power provides an SCR for tail-end applications, where they direct flue gas through a regenerative thermal oxidizer (RTO), which is a large ceramic bed that can absorb and release heat. The flue gas would then pass through the first layer of an SCR and after that, it would be heated by a duct burner and pass through a second layer of catalyst. After the second layer, it will pass through another RTO, this time transferring heat into the second RTO. Once the first RTO's heat has dissipated, the cycle is reversed so flue gas passes through the second RTO before passing through the catalyst. Babcock Power's process is termed a Regenerative SCR (SCR), and it is typically more expensive than a traditional SCR due to the additional components.

Cost Estimates
Black & Veatch has been employed on many projects and studies over the years with power-related equipment and air quality controls. From these experiences, high-level cost estimates were calculated for implementing heating and cooling options for the flue gas. These past projects were based on design conditions from past clients, cost quotes from vendors, and engineering design specifications developed by Black & Veatch. These are not included in EPA's Control Cost Manual, as these would be unique to this particular application for EAFs. These estimates are not budgetary in nature, as more time and effort would be required for that level of accuracy, but rather, these estimates are provided to give a general idea of the additional costs that would be incurred to install an SCR. A facility specific detailed engineering design would be required in order to develop more precise cost estimates. Table 1 summarizes the cost estimates for each EAF for adding a tempering air, spray water system, and duct burner to the Big River Steel EAF. Other options for heating the flue gas were not considered, because duct burners are the simplest option for attempting to address the incompatibility of Big River Steel's EAF options and SCR.

Table 1 Cost Estimate Summary for Flue Gas Temperature Control Options

Option	Equipment Cost	Installed Cost
Tempering Air	$7,250,000	$11,700,000
Spray Water System	$7,400,000	$11,200,000
Duct Burners	$20,000,000	$27,800,000

The above costs include nominal ductwork and piping due to the fact that most studies serving as the cost estimates' basis were greenfield sites. The layout of Big River Steel's facility would increase the costs for these items due to its size and complexity (although the amount of increase is not known at this juncture). The EAF is a large structure, and the platforms that fans and pumps would be located are far away from the flue gas ductwork.

Other Considerations for Installing an SCR
In addition to the flue gas temperature concerns, there are other potential challenges that must be confirmed before an SCR can be installed. A common theme to these issues is the custom design of Big River Steel's facility. When the facility was designed and commissioned, the inclusion of a substantial new emission control system like SCR was not accounted for in the design, so the installed equipment will have challenges in accommodating an SCR. These include:

1) Flue gas passing through an SCR will experience a pressure drop due to flow resistance from passing through the SCR's catalyst and additional ductwork. The pressure drop should be around 4 inches w.g. (but could be larger). It is common on SCR retrofits for a booster fan to be added to the system's draft system, or the existing ID fans can be retipped to increase their capacity, to overcome this additional pressure drop. Further evaluation of the draft system and fans is required, but at this time, it is believed that a new booster fan will be required.

   Even if the existing draft fans were capable of providing the additional pressure drop, the auxiliary electrical system may not be able to support the additional power required by the fans.

The installed auxiliary electrical system does not have much additional capacity, and further analysis is required to confirm the amount of new cabling, transformers, etc. that will be required to even attempt providing the additional power needed. This also would require detailed facility specific engineering not possible to complete during the 2.5 month comment period in this rulemaking.

2) There is limited operational space at Big River Steel's facility, particularly around the EAF. The EAF is within a large structure that is highly congested with equipment, piping, and ductwork, and little space is available for installing a tempering air skid, ammonia handling system, and ammonia pump skid. The location for the SCR itself will also require more analysis. The ductwork between the EAF and the baghouse goes over a major road at the facility that is accessed by large haul trucks that require significant clearance levels. Accordingly, any attempt to employ an SCR upstream of the baghouse would have to be elevated with a steel support system that does not interfere with the roads. Assuming such a configuration can be accomplished, it would increase the installation cost significantly (these challenges were not accounted for in the cost estimates in Table 1).

   At the back-end of the baghouse there is only about 12.5 feet of space between the baghouse and the stack, and the ID fan is located adjacent to the stack. Even if it's possible to tie in the SCR's inlet duct between the baghouse and stack, but 12.5 feet may be too narrow for tying in the SCR's outlet duct at the same location. The outlet duct's tie-in point would need to return to the system upstream of the ID fan, which could require a stack breeching and other considerations. This also would require detailed facility specific engineering not possible to complete during the 2.5 month comment period in this rulemaking.

   Barring substantial modifications to the plant flue gas system, there is no appropriate location to site a booster fan. As there is no room between the ID fan and the stack, as the two are adjacent to one another, any booster fan would need to be located off to the side of the baghouse or behind the stack. The ductwork tying in the booster fan would therefore require multiple turns that would increase the pressure drop it needs to provide.

   As a result, there is no appropriate location where SCR can be guaranteed to be feasibly installed. Further analysis is required to determine where an SCR and other supporting equipment could feasibly be located, if at all.

3) The particulate matter produced by the EAF was analyzed for potential catalyst poisons, as there is significant concern regarding alkali metals that have been known to poison SCR catalysts. One prominent example is an SCR installation at Coyote Station in North Dakota. North Dakota lignite is burned at the facility, and it is known to have elevated levels of sodium. At Coyote Station, the SCR experienced detrimental plugging issues due to the sodium in the flue gas. Potassium-based poisoning is well-known throughout the power industry, especially for the case of power stations that have attempted to co-fire significant amounts of high-potassium biomass fuel.

The particulate matter from the EAF captured by the baghouse has potassium and sodium levels of 11,500 and 8,080 ppm, respectively. These tested levels for potassium and sodium appear to be high, but the dust concentration is not as large compared to coal-fired power plants. Black & Veatch has contacted catalyst suppliers for their advice regarding use with these high potassium and sodium concentration levels, but no conclusions have been attained at this time. Further analysis is required to determine the effects of the particulates' composition on catalysts.

4) Ammonia slip is a consideration for SCR design, with more catalyst being typically required to achieve lower ammonia slip. Ammonia slip is often increased by swings in flue gas temperatures, variations in the flue gas flow rate, the level of catalyst poisoning, the amount of wear and pluggage in the ammonia injection grids, etc. The potential for ammonia slip will need to be confirmed through the permitting and regulatory process.

Other NO_X Reduction Options:

The EPA proposed ruling is based on deploying an SCR, but as summarized in this memo, there are multiple issues with implementing an SCR at Big River Steel's EAF. The proposed limit is not restricted to being met solely by an SCR, so some consideration should be given to whether alternative control options would be able to meet the proposed limits.

NO_X control methods can be generally categorized into two groups for typical utility boiler applications, pre-combustion and post-combustion. Pre-combustion refers to ways to control the formation of NO_X. NO_X is primarily created when nitrogen in the air is combusted. Nitrogen in fuels, or in this case scrap metal, can also be combusted to create NO_X, but the rate of NO_X from fuels is minor compared to NO_X from the air. Sensibly, one of the ways to reduce NO_X formation is to lower the flame temperatures. For traditional furnaces, this is accomplished by using low-NO_X burners (LNBs) that control the mixing of fuel and air in a pattern designed to minimize flame temperatures. However, melting scrap metal in the EAF is primarily driven by electricity rather than by a flame or combustion of fuel, so LNBs cannot be relied on for further reductions. Neither are other pre-combustion methods, such as over-fire air (OFA), due to the lack of combustion. Further analysis is required to determine if there are ways to optimize the electric arcs in the EAF to minimize NO_X formation, but since the electric arcs are integral to melting scrap metal, there is doubt as to whether this can be accomplished.

Post-combustion control methods refer to ways to remove NO_X after it has been generated. SCRs are the most common post-combustion control method in some other industries for achieving significant levels of NO_X reduction, but when the reduction levels are less demanding, selective non-catalytic reduction (SNCR) systems are an option. SNCR systems inject urea solutions into furnaces where the temperature is optimal for NO_X and NH_3 reactions. However, the flue gas temperature at the EAF outlet varies too greatly and is too low for SNCR to be implemented. An SNCR system will typically require temperatures to be consistently greater than 1,550 °F in order to provide NO_X reductions. Black & Veatch confirmed with Fuel Tech, a leading provider of SNCR systems, that an SNCR is not practical for EAFs, and that they have not installed an SNCR at any EAF.

Conclusion:

Based on Black &Veatch's experience, research, and discussions with suppliers, installing an SCR at Big River Steel's EAFs is technically infeasible without making major modifications to the system, and it is unknown whether the EPA has considered the cost of these major modifications in their proposed ruling. Even if these modifications were made, there are potential challenges to installing and successfully operating an SCR that will need detailed facility specific engineering investigation. Black & Veatch would be happy to assist Baker Hostetler in providing Big River Steel further support as needed on this issue, as well as any other issues that arise.

Very truly yours,

Black & Veatch Corporation

UNITED STATES STEEL CORPORTATION

COMMENTS ON

PROPOSED FEDERAL IMPLEMENTATION PLAN

ADDRESSING REGIONAL OZONE TRANSPORT FOR

THE 2015 8-HOUR NAAQS.

June 21, 2022

<u>EXHIBIT C:</u>

Barr

COMMENTS TO THE

UNITED STATES STEEL CORPORATION

Regarding the

Proposed Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standard

87 Fed. Reg. 87,66 (April 6, 2022)

Docket ID No. EPA-HQ-OAR-2021-0668

June 21, 2022

TABLE OF CONTENTS

LIST OF TABLES

Included herein are technical comments from Barr Engineering Co. ("Barr") in response to the U.S. Environmental Protection Agency's ("EPA" or "the Agency") *Proposed Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standard; Proposed rule*, 87 Fed. Reg. 87,66 (April 6, 2022) ("Proposed Rule"), based on review of the Proposed Rule and its supporting technical documentation.

I. Taconite Iron Ore Processing Industry should be Excluded from the Proposed Rule Applicability since it is not part of the Iron and Steel Mills and Ferroalloy Industry

A. EPA's Proposed Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standard should exclude the Taconite Iron Ore Processing Industry from the final rule for the following reasons and relevant supporting documentation:

1. The Taconite Iron Ore Processing Industry is not part of the Iron and Steel Mills and Ferroalloy Industry, as defined by the Taconite Iron Ore Processing Industry 4-digit NAICS codes and by the definition under 40 CFR 63. The NAICS description of Iron and Steel Mills and Ferroalloy Manufacturing corresponds to a NAICS code of 3311 and the NAICS description of Metal Ore Mining corresponds to a NAICS code of 2122. The Taconite Iron Ore Processing Industry (NAICS code 212210) is a subset of the Metal Ore Mining Industry.
2. Throughout the Proposed Rule, EPA refers to the '*seven non-EGU industries that provide opportunities for NOx emissions reductions that result in <u>meaningful impacts</u> on air quality at the downwind receptors*.' The seven industries identified by EPA in the "Screening Assessment of Potential Emissions Reductions, Air Quality Impacts, and Costs from Non-EGU Emissions Units for 2026" ("Non-EGU Screening Assessment memorandum") (EPA-HQ-OAR-2021-0668-0150) are shown in the below table.

Tier 1 Industries		Tier 2 Industries	
NAICS Description	NAICS Code	NAICS Description	NAICS Code
Pipeline Transportation of Natural Gas	4862	Basic Chemical Manufacturing	3251
Cement and Concrete Product Manufacturing	3273	Petroleum and Coal Products Manufacturing	3241
Iron and Steel Mills and Ferroalloy Manufacturing	3311	Pulp, Paper, and Paperboard Mills	3221

Glass and Glass Product Manufacturing	3272		

3. In the "Non-EGU Screening Assessment", the Metal Ore Mining Industry (4-digit NAICS 2122) was originally included as a Tier 2 facility; however, in a later step in the analysis EPA refined the Tier 2 grouping by identifying potentially impactful industrial, commercial, and institutional (ICI) boilers, using the projected 2023 emissions inventory in the linked upwind states, which subsequently removed the Metal Ore Mining industry from the Tier 2 grouping as this industry was found to not have any "potentially impactful boilers" (See Table 1: Number of Emissions Unit Types in Tier 2 Industries in the Non-EGU Screening Assessment). Based on EPA's own assessment, boilers in the Metal Ore Mining industry, which would include the Taconite Iron Ore Processing facilities, do not provide opportunities for NOx emissions reductions that result in meaningful impacts on air quality at downwind receptors.
4. NOx emissions from taconite production kilns/indurating furnaces are already well controlled and regulated by the Minnesota Taconite Regional Haze BART FIP 81 FR 21671 (April 12, 2016), as amended most recently for Minntac on March 2, 2021 (86 Fed. Reg. 12095, codified at 40 CFR 52.1235). Because the industry is already well controlled and because EPA and the regulated community have already invested significant amounts of resources in determining appropriate NOx limits for indurating furnaces, it is unnecessary and inappropriate for EPA to now impose additional requirements to the industry.
5. In Section VII.C.3 of the Proposed Rule (20148), EPA states:

"The EPA did not find large boilers within the Lime and Gypsum Product Manufacturing (NAICS code 3274xx) or the Metal Ore Mining industries (NAICS code 2122xx). As such the EPA is not expressly proposing to include boilers in those industries. However, if as a result of receiving additional information during the comment period the EPA identifies large boilers within these two industries that meet the applicability criteria described below, those boilers could be subject to the requirements of the final rule."

Since no 'potentially impactful boilers' were identified from the Metal Ore Mining industry as part of EPA's "Non-EGU Screening Assessment" it is still not a 'potentially impactful boiler' because it would have been originally included in EPA's "Non-EGU Screening Assessment" and therefore should be removed from reference in the rule.

B. Discrepancies in the Screening Assessment of Potential Emissions Reductions, Air Quality Impacts, and Costs from Non-EGU Emissions Units for 2026 ("Non-EGU Screening Assessment memorandum") warrant further quality assurance and explanation.

1. (EPA-HQ-OAR-2021-0668-0150), a supporting document to EPA's RIA, presents the analytical framework EPA used to "facilitate decisions about industries, emissions unit types, and cost thresholds for including emissions units in the non-electric generating unit 'sector' (non-EGUs)" and "summarizes the screening assessment the EPA prepared to identify industries

and emissions unit types to include in the proposed rule to obtain NOx emission reductions from non-EGUs."

To analyze non-EGU emissions units, EPA aggregated the underlying projected 2023 emissions inventory data into industries defined by 4-digit NAICs, focused on assessing emission units that emit >100 tpy of NOx. The focus was limited to potentially controllable emissions, and well-controlled sources that still emit >100 tpy were excluded from consideration. EPA then grouped the industries into Tier 1 and Tier 2 categories, as defined above.

Originally, Metal Ore Mining (4-digit NAICS 2122) was included in the Tier 2 grouping; however, in a later step EPA refined the Tier 2 grouping by identifying potentially impactful industrial, commercial, and institutional (ICI) boilers, using the projected 2023 emissions inventory in the linked upwind states, which subsequently removed the Metal Ore Mining industry from the Tier 2 grouping. Based on EPA's own assessment, boilers in the Metal Ore Mining industry, which would include the MN taconite facilities, do not provide opportunities for NOx emissions reductions that result in meaningful impacts on air quality at the downwind receptors. Accordingly, application of the Proposed Rule to Taconite facilities is not supported by the underlying modeling because (1) the taconite facilities are not part of the Iron and Steel Mills and Ferroalloy Manufacturing Industry and (2) the Metal Ore Mining industry was removed from consideration in EPA's screening assessment.

Furthermore, boilers at taconite facilities that emit or have the potential to emit >100 tpy of NOx are not expressly listed under the text of the Proposed Rule as an "Affected Unit" (unlike a "taconite production kiln"). Instead, section 52.43 with respect to boilers only includes "industrial boiler" "at an iron and steel mill or ferroalloy manufacturing facility." Because taconite production is not in fact within the iron and steel mill or ferroalloy NAICS, it is unclear whether boilers at taconite facilities that emit or have the potential to emit >100 tpy of NOx are subject to the Proposed Rule as currently drafted. And in any case the underlying modeling cannot support application of the Proposed Rule to such boilers because boilers in the Metal Ore Mining industry were removed from consideration in EPA's screening assessment.

C. Inconsistencies with Iron and Steel Mills and Ferroalloy Manufacturing Industry 30-day rolling average vs. 3-hour rolling average for Gas-Fired Industrial Boilers require updating.

1. VII.C.3 states "In determining the averaging times for the limits, EPA initially reviewed the NESHAP for Iron and Steel Foundries codified at 40 CFR part 63 subpart EEEEE, the NESHAP for Integrated Iron and Steel manufacturing facilities codified at 40 CFR part 63 subpart FFFFF, the NESHAP for Ferroalloys Production: Ferromanganese and Silicomanganese codified at 40 CFR part 63 subpart XXX, and the NESHAP for Ferroalloys Production Facilities codified at 40 CFR part 63 subpart YYYYYY. EPA also reviewed various RACT NOX rules from states located within the OTR, several of which have chosen to implement OTC model rules and recommendations. Based on this information, the ***EPA is proposing to require a 30-operating day rolling average period as the averaging time frame for this particular industry***. The EPA finds that a 30-operating day rolling average period provides a reasonable balance between short

term (hourly or daily) and long term (annual) averaging periods, while being flexible and responsive to fluctuations in operations and production." (20145)

VII.C.5.c for Gas-Fired Industrial Boilers states "The proposed NOx emissions limits for gas-fired boilers subject to the requirements of this section is 0.08 lbs/mmBtu. The ***proposed averaging time for these emissions limits is a 30-day rolling average***. Additionally, EPA seeks comment on whether the EPA should establish less stringent emissions rates for boilers with low utilization rates, and if so, the appropriate emissions rate(s) and corresponding boiler utilization rate(s)." (20149)

§52.43(c) – "*Emissions Limitations and Requirements.* Beginning with the 2026 ozone season and in each ozone season thereafter, the ***emissions limitations in the following table must be met on a 3-hour rolling average***." (20181) Note: this is the only mention in the proposed FIP of a 3-hour rolling average.

There is inconsistency between the averaging time for the gas-fired industrial boiler emissions limits. Sections VII.C.3 and VII.C.5.c specify a 30-day rolling average and §52.43(c) specifies a 3-hour rolling average.

Boilers in the Tier 2 industries are also subject to a 30-day rolling average period as specified at §52.45(d)(2) & (e)(5), thus it would be inconsistent with the rest of the Proposed Rule not to use a 30-day rolling average period for boilers in the iron steel and ferroalloy industry (and taconite boilers if covered under that section). Additionally, there is no justification offered in the Proposed Rule or its supporting documents for a 3-hour averaging period.

D. A 3-hour Rolling Average Standard is Unsupported by Real-Time Ozone Transport Cross-State.

1. The rule is designed to address pollutant transport during the ozone season and any 1-hour, 3-hour, or even 24-hour restrictions are not necessary. Ozone transport across multiple states (or even a single state) would not be responsive to this type of short duration when emissions occur. The transport times can be days from sources to downwind receptors and vary considerably. The justification for a 3-hour rolling average does not exist. Short term averages are typically applied when there is a direct response between the downwind concentration and the emissions. For example, a 24-hour limit on a facility that is evaluating the 24-hour PM10 standard at its property boundary (i.e., much more direct cause and effect) matches the form of the standard with the source emissions limit. This type of short-term limit is not being discussed as part of the ozone transport FIP and shouldn't be.

2. The other limitations from the rule all include a 30-day rolling average. While this is better, EPA should clarify that monitoring recordkeeping and reporting are only required during the ozone season since the Proposed Rule's limits only apply during the ozone season. The use of a 30-day rolling average during the winter months is completely unnecessary as ozone concentrations are not elevated outside the ozone season (traditionally May – September) in many areas. EPA's proposal is an excessive limitation beyond the scope of the ozone transport

issues that they believe they are trying to resolve. If EPA moves forward with controls in Minnesota, it is Barr's recommendation that an ozone season total emission limit is the appropriate form and not an on-going 30-day rolling limit. This is consistent with the NOx transport rule and CSAPR, along with the other ozone transport state rules/SIPs designed to address ozone transport.

EPA's own statement applies good logic about using a longer average notwithstanding the ozone season issue discussed above - **"**The EPA finds that a 30-operating day rolling average period provides a reasonable balance between short term (hourly or daily) and long term (annual) averaging periods, while being flexible and responsive to fluctuations in operations and production."

II. EPA's Technical Modeling Analysis Justifying the Inclusion of Non-EGU Taconite Sources.

A. Is EPA's modeling approach for identifying upwind states to include in their future ozone attainment regional scale modeling and source type category contributions justified?

1. *EPA should reconsider the 1% (0.71ppb) threshold for identifying a state's contributions "significant" to a future modeled ozone NAAQS non-attainment downwind receptor. The August 2018 memo provided a reasonable argument for adjusting the significant level to 1 ppb.*

EPA's reasoning for retaining the 1% NAAQS threshold for the latest revisions to the Good Neighbor Rule makes it seem like adjusting the threshold will throw mass confusion into the entire process and make it unfairly apply tighter restrictions to some states and not others. To quote their own defense

> "Where alternative thresholds for purposes of Step 2 may be "similar" in terms of capturing the relative amount of upwind contribution (as described in the August 2018 memorandum), nonetheless, use of an alternative threshold would allow certain states to avoid further evaluation of potential emissions controls while other states must proceed to a Step 3 analysis. This can create significant equity and consistency problems among states."

This argument contradicts itself by assuming that the 1 ppb would not be applied uniformly across all states, avoiding the consistency and equity problems. If 1 ppb captures the same relative amount of upwind contribution, then the fact that some upwind states impacts would not be considered significant and require a Step 3 analysis is reasonable. In fact, the Proposed Rule stated that "EPA's updated modeling, the amount of upwind contribution lost is 5%)". The same argument for fairness could be applied to a 1% standard which unduly burdens states to more stringent control requirements when applying these controls will result in little to no benefit of downwind Ozone. (This is further discussed in item 4.)

The August 2018 memorandum stated, “Each time EPA sets a new or revised NAAQS, states and EPA can evaluate collective contribution to identify an appropriate threshold for that NAAQS…conclusions made with respect to one NAAQS are not by default applicable to another NAAQS.” Yet here, EPA’s Proposed Rule makes the argument that “Consistency with past interstate transport actions…is also important.”

It is understood that generalizations and simplified assumptions are sometimes appropriate and necessary in a complex modeling analysis such as a national photochemical ozone evaluation. However, when the results are used to justify costly controls and monitoring on a significant number of industrial stationary sources in the state, further culpability refinements need to be assessed. Arbitrarily requiring controls across multiple non-EGU point sources in a state contributing less than 1ppb to a modeled ozone value greater than 70 ppb demands an extra step confirming that non-EGU sources are in fact the main contributors from each state.

2. *The use of 1% of the NAAQS as a meaningful level to evaluate other source/source geographies (especially on a state-basis) is flawed as it ignores the impact of the downwind nonattainment areas and other impacts from within the immediate vicinity around the area.*

Using a very small contribution simply means that more sources will be included as impacting downwind nonattainment. The selection of the level should be based on similar criteria that are used as part of an individual project evaluation, but with a much larger impact when combining emissions sources from an entire state. This is a substantial flaw in EPA’s approach and should be recognized along with the inherent bias and error of the model to determine applicable thresholds which is further discussed in item 6.

EPA ozone modeling evaluated baseline 8-hour impacts for 2023 and 2026 with contributions by state to any ozone NAAQS modeled exceedance. This information is contained in Appendix C: Ozone Contributions to Nonattainment & Maintenance-Only Receptors (Outside of California) in 2023 and 2026. The following table lists the state receptors in Appendix C where U. S. Steel facilities are located which contribute more than 0.71 ppb to a downwind ozone non-attainment (>70 ppb) receptor. The State of Illinois’s contribution to downwind ozone (including all sources, not merely EGUs and Non-EGUs) is the greatest with around 25% of the impact with Pennsylvania and Indiana coming next with around 10% impact on their downwind receptors. The remaining states only contribute around 2-3% of the downwind ozone impacts even when all sources are combined in the state (including natural sources and mobile sources and other sources not subject to the Proposed Rule).

3. *EPA's ozone modeling results indicate that the non-EGU sources' contributions are a small fraction of the state's total downwind impacts to ozone non-attainment receptors. Without the complete culpability of a state's total impacts to downwind receptors identifying the main contributors from each state, EPA's argument that non-EGUs need to be controlled for future ozone NAAQS demonstration is not justifiable for the proposed rule.*

Section 4.1 of the "**Air Quality Modeling Technical Support Document: FIP Addressing Regional Ozone Transport for 2015 Ozone NAAQS Proposed Rule Making**" explains the make-up of the state-wide emissions. They include point sources (electric generating units (EGUs) and non-EGU's (combustion stacks)), non-point sources (mobile vehicle exhaust, other man-made (anthropogenic) sources), and biogenic sources (forest fires). The 2026 Ozone NAAQS modeling was the only run that sub-divided state-specific culpability into EGU and non-EGU source culpabilities. The USS facilities would be classified as a non-EGU source and are assumed included within the non-EGU source group contributions. EPA 2026 ozone modeling results provided state-sector contributions for all ozone NAAQS non-attainment receptors further sub-divided into EGU and non-EGU sources; it did not include a source category for non-point anthropogenic sources (on-road and off-road vehicles) or biogenic sources. The docket file "**EPA-HQ-OAR-2021-0668-0070_content_2026_non-egu-state-sector_contribution.xlsx**" provided this apportionment for all the 2026 receptors in Appendix C.

The tables below summarize each state U. S. Steel facilities reside in non-EGU contribution to the modeled total ozone in ppb. In general, non-EGU sources are around 20% of the state-wide contributions and when combined with the EGU's are approximately 50% of each state's contributions. For 46 receptors (80%) of the 57 receptor, non-EGU contributions are insignificant enough that subtracting the entire non-EGU inventory from each receptor would not affect whether the state was a "significant" contributor to the ozone NAAQS assuming EPA's significance threshold for States of 0.71

ppb. The remaining state impacts by process of elimination are some fraction of mobile sources, non-point sources, and biogenic sources.

a. With particular focus on Minnesota's modeled impacts and industrial sources, U.S. Steel has two northeast Minnesota facilities included in the analysis: Keetac and Minntac. Minnesota's non-EGU source group contributions (all non-EGU's including Minntac and Keetac) to the state's culpability in Cook County, IL were 0.19 and 0.18 ppb. The distance and time needed for these sources' NO_X emissions to travel to Chicago to chemically react and create ozone at this monitor seems unlikely and was further investigated. EPA provided the dates and times of the 2016 top-10 ozone days for the two IL monitors Minnesota contributed more than 0.71 ppb and using the HYSPLIT web-based platform, preliminary 48-hr back trajectories were processed for these dates. While a simplified approach, it provided results that require EPA to re-assess their modeling culpability. In general, the preceding hours to the highest ozone impact days had very little to zero winds coming from the northwest (i.e. Minnesota).

4. *EPA's analysis chose to not address any reductions on non-point sources like mobile traffic which include light and heavy-duty trucks and passenger vehicles. However, EPA's modeling indicates the mobile sources are a higher fraction of an upwind state's contribution then non-EGU sources. EPA's rule should include federally enforceable limits on mobile traffic as a larger source contributor rather than requiring additional NO_X controls and limits on non-EGU point sources that contribute far less.*

"The EPA accounted for mobile source emissions reductions resulting from other federally enforceable regulatory programs in the development of emissions inventories used to support analysis for this proposed rulemaking, and the EPA does not evaluate any mobile source control measures in its Step 3 evaluation in this proposal." Item 3 highlights the need for a more refined breakdown of state-source contributions to modeled ozone non-attainment. There is no mention in the air quality modeling technical support document of the word "mobile" or "vehicle." (Federal Register Vol 87. No. 66 VI.A.)

On May 16, 2022, the National Association of Clean Air Agencies (NACAA) provided comments on EPA's Notice of Proposed Rulemaking "Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards" which included relevant information to this proposed Good Neighbor Ozone Rulemaking. NACAA's main point is how the last 20 years has seen a significant reduction of NO_X from point sources while heavy-duty vehicles have not made much progress. This plays out in nationwide Ozone attainment where the largest contributors across many regions of the US are mobile sources, particularly heavy-duty trucks. Some pertinent quotes from NACAA's comment letter are provided as further reasons to use the evidence from the ozone modeling to identify the highest contributing sources (regardless of type) and focus on those that provide the greatest ozone downwind reductions.

> "HD (heavy duty) trucks will continue to be one of the largest contributors to the national mobile source NOX inventory in 2028 without additional regulations to reduce emissions."
>
> "The excessive emissions from HD trucks are a primary cause, contributing substantial emissions of NOX – the key pollutant contributing to the formation of ozone and PM2.5."
>
> "While state and local agencies have made great strides in reducing emissions from stationary sources, for the most part they lack the authority to regulate mobile sources and never do they have the authority to regulate mobile sources upwind of or across their borders. The regulation of mobile sources is an authority that lies almost entirely within the purview of the federal government."
>
> "**Many areas will be forced to adopt severe limits on stationary sources**, for which they have authority to control**, at ever-increasing costs, if reductions from such sources are even available**." (Emphasis added)
>
> "The onroad mobile sector is the largest contributor of NOX emissions in Wisconsin. Recent modeling done by the Lake Michigan Air Directors Consortium indicates onroad diesel vehicles, the vast majority of which are heavy-duty vehicles, contribute up to 8 ppb of 11% of ozone at Wisconsin's lakeshore nonattainment monitors."
>
> "Recent source apportionment modeling for 2023 (Denver Metro, CO) demonstrates that NOX emissions are driving ozone formation at monitors throughout the region and that medium- and heavy-duty truck traffic is a significant contributor to ozone formation."

The last two quotes are relevant for the Kenosha and Racine, WI monitors and Denver, CO monitor that are part of the list where non-EGU sources in upwind states are being considered for further NO_X reductions to reduce ozone impacts. The regional scale modeling conducted by these collectives at a finer scale highlight how significant heavy-duty vehicle traffic is to the ozone impacts. The 2023 apportionment modeling listed in the above quote lists the total mobile vehicle contribution to the Denver 011 monitor for a 10-day period 8-hour ozone concentration of 20 ppb as 31% with 26% of the 31% due to light-duty vehicles. The non-EGU sources compose 15% of the total (i.e., all non-EGU industries combined are still less than half the contribution that mobile sources add to the state's linked receptors).

5. *The non-EGU controls considered for Tier 1 and Tier 2 sources do not meaningfully reduce the ozone concentrations at non-attainment receptors. EPA's state contribution significance threshold of 0.71 ppb exceeds the*

potential downwind ozone reductions through excessive controls on these state's non-EGU sources.

As part of its evaluation, EPA defined "impactful boilers" using 3 criteria[1]: (1) estimated maximum air quality contribution at an individual receptor of greater than or equal to 0.0025 ppb or estimated total contribution across downwind receptors of greater than or equal to 0.01 ppb (2) controls that cost up to $7,500 per ton (3) estimated maximum air quality improvement at an individual receptor of greater than 0.001 ppb.

EPA acknowledges the fact that the model is not precise enough to confirm these types of regulatory decisions but does so, nonetheless. When trying to define the impact of individual sources on downwind ozone nonattainment areas, EPA is trying to draw the conclusion that a source with a 0.0025 ppb contribution is "impactful". This level is not impactful and as a statistical matter cannot even be differentiated by the model used by EPA.

Additional information included in "**Appendix A**" specifies industries maximum contributions to downwind ozone receptors. Table A-2 lists both Iron and Steel Mills and Ferroalloy and Nonmetallic Mineral Mining and Quarrying separately. Iron and Steel Mill's maximum downwind impact is 0.129 ppb and contributes more than 0.01 ppb to 11 downwind receptors. Nonmetallic mineral mining's maximum downwind impact is 0.035 ppb and has only 4 receptors that it contributes more than 0.01 ppb.

As noted in the above section 3, in almost all states evaluated by EPA, non-EGU contributions are so insignificant that even if every single non-EGU source was wholly eliminated, that would not affect the significance of a state's contribution to its linked receptors. By contrast the overall contribution of other sources (including mobile sources within the nonattainment area) are orders of magnitude greater than this level of impact and not being considered for reductions. Accordingly, it appears the Proposed Rule was designed to make sources across the country address ozone air quality issues within major metropolitan areas where the largest impacts come from mobile and area source emissions. The underlying modeling does not justify a finding that non-EGU sources, whether combined or separately, are significant contributors to non-attainment.

6. *EPA's reliance on a significance of 0.71 ppb is faulty when taking into consideration their model performance evaluation of their ozone modeling evaluation. A higher ppb downwind impacts threshold than 0.71 ppb should*

be considered when the modeling TSD states "the regional mean bias of the model is +/- 5 ppb and the mean error is between 6 and 7 ppb on average for all days during the period May through September in each region."

The model performance at each non-attainment receptor was provided in the proposed rule docket file "EPA-HQ-OAR-2021-0668-0071_content(2016CAMxperformance).xlsx". The following table lists the model's performance reflected by the (1) difference between the model vs observed mean 2016 concentration, (2) calculated mean bias, (3) mean error, and (4) standard deviation. In general, the receptors downwind of U.S. Steel located states had a higher variability in model performance than the +/- 5 ppb overall regional model bias. All receptors modeled ozone concentrations less than the observed concentrations underpredicted ozone concentrations with a mean error ranging from 7-17 ppb. Given the substantial model error compared to the extremely low alleged upwind state contributions, EPA's model is not capable of reliably differentiating between any effect within an order of magnitude of the significance threshold selected by EPA.

Receptor Information	Model/Obs. (ppb)	Mean Bias (ppb)	Mean Error (ppb)	Standard Deviation (ppb)

III. Installation and Permitting Schedule Challenges.

A. Is the proposed permit schedule for required new NO_X controls and/or construction reasonable based on current permitting issuance timelines?

1. The amount of time it takes for an air permit application review and issuance of an air permit varies by state and source type. An optimistic assumption is the application approval process in general will be swift and streamlined due to the large number of sources requiring additional control and monitoring equipment to reduce NO_X emissions. A more likely outcome, based on experience in certain states, is that the combination of staff availability and the large volume of permit applications to review and approve makes the current schedule unachievable.

Each state has different approaches to reviewing an air permit application and issuing the air permit for an existing stationary source. Some require more information and scrutiny of proposed updates than others which effects each state's ability to meet the 2026 deadline for the non-EGU to comply with the proposed rule. Minnesota in particular has some of the longest permitting review times in the country currently without the addition of this many permit applications in such a short timeframe. The table below lists out the likely timeline for each Minnesota USS facility to receive an approval of their air permit application and the assumptions of what the application will entail. This is without considering the construction and installation schedule.

Permitting Stage	Timeframe	Assumptions
Prepare application	5 months	Minor Amendment on existing Major Source; Keetac air permit requires Equivalent or Better (EBD) dispersion modeling analysis on "changes that affect any modeled parameter" in the SO2 and NO2 source list.
Application submittal	1.5 months	Currently 6 weeks wait time for a permit application assignation at MPCA
Regulatory approval	11.5 months	MPCA online permit flexibility table lists Individual part 70 permits issuance time as 6-12 months of starting work (9 months is mid-point); plus 30 day public notice, plus EPA 45-day review
Total	18 months	Assumes EBD demonstration acceptable and no negative comments from EPA or public

Based on the current situation, it will take a year and a half to complete the air permit application process and approve the air permit to begin project construction. The current queue timeline of 1.5 years is likely subject to change and increase with the large volume of projects that will be arriving simultaneously to meet the proposed construction schedule of this proposed

Good Neighbor Rule. In addition to the time needed just to obtain initial permits, new equipment installation scheduling will be affected by logistical/supply chain issues related to multiple sources needing upgrades at the same time

B. New Equipment Installation Scheduling will be affected by permit timeline challenges.

1. The proposed rule as written required all facilities to install controls by 2026. EPA should revise the schedule for installation as it is infeasible as currently written for a few reasons. Most of the facilities that are subject to installing controls will require retrofitting of existing equipment, therefore will require time to engineer and design the modifications required for installation of the controls, which could take months and years depending on the facility and equipment. Once modifications for existing equipment and proposed controls are designed, procurement of the necessary materials could take months and years due to potential supply chain issues. Most facilities will be competing to obtain materials from the same suppliers as the number of suppliers for the proposed controls is a very small group. Therefore, if EPA still determines it is feasible for the facilities to install the proposed controls after review and consideration of other supporting information as to why the proposed rule is infeasible, EPA should revise the proposed installation schedule by 5 years to allow sufficient time to design, procure, construct, and startup the proposed control equipment for a compliant demonstration.

IV. Infeasibility of SCR Installation for Iron and Steel Mills and Ferroalloy Manufacturing Emission Units

Table VII.C.3 – Summary of Proposed NOx Emissions Limits for Iron and Steel and Ferroalloy Manufacturing Emissions Units of the proposed rule lists 10 types of emissions units along with the proposed NOx emissions standard or requirement for each. A Regional Haze Four-Factor Analysis for NOx and SO2 Emission Controls was prepared for USS Gary Works in September of 2020. This analysis covered the No. 3 Sinter Plant Sinter Strands, the No. 14 Blast Furnace Stoves and Casthouse, and the 84" Hot Strip Mill Reheat Furnaces No. 1 through No. 4 and Waste Heat Boilers No. 1 and No. 2. This analysis covers three emissions units included in Table VII.C.3 of the proposed rule – blast furnace, reheat furnace, and boiler (natural gas-fired). The results of the Gary Works' FFA found that:

- For the No. 14 Blast Furnace (Stoves and Casthouse)
    - Already utilize low-NOx fuel combustion (blast furnace gas) as a NOx emission control measure,
    - There is no reasonable set of NOx emission control measures beyond what is currently installed and operated for these emission units, and
    - The existing emission control measures are equivalent to those determined to be the Best Available Control Technology (BACT) in a recent BACT analysis and, therefore, are considered effective emission controls.

- For the 84" Hot Strip Mill Reheat Furnaces and Waste Heat Boilers
  - Low-NOx Burners (LNB) were an available NOx emission control measures beyond what is currently installed and operated for these emission units, but LNB installation on the 84" Hot Strip Mill Reheat Furnaces and Waste Heat Boilers are not cost-effective, based on the associated cost-effectiveness values ($ per ton of emissions reduction).
- Additional emission control measures could impact the economic viability of the company to continue to operate in competitive economic markets. Gary Works, as well as the entire integrated iron and steel mill industry, is highly sensitive to incremental capital and operating costs due to substantial fluctuation in global economic markets. Any additional emission control measures would be a substantial barrier for the facility to continue to operate and are therefore unreasonable and inappropriate.

EPA projects that use of LNB or LNB plus SCR will result in minimally 20-50% NOx reduction efficiency if implemented on blast furnaces, reheat furnaces, and boilers. The Gary Works' FFA is one example that found that implementing additional NOx controls on these emissions units is technically and/or economically infeasible. The proposed requirements are not supported by the necessary engineering analyses and contradict past Best Available Control Technology (BACT) determinations established by permitting authorities.

For Electric Arc Furnaces, EPA is proposing a NOx emissions standard of 0.15 lb/ton steel. A RACT/BACT/LAER Clearinghouse search returns 3 LAER determinations with emissions limits of 0.27 lb/T, 0.27 lb/T, and 0.35 lb/T for Nucor Kankakee (2021, RLBCID = IL-0132), Nucor Auburn (2006, RBLCID = NY-0099), and Republic Engineered Products (2006, RBLCID = OH-0302), respectively. EPA's proposed standard contradicts these LAER determinations established by permitting authorities. Also, for CMC Steel Oklahoma (2016, RBLCID = OK-0173) the Pollutant Compliance Notes state: 'The application proposes oxy-firing as BACT for NOx to a level of 0.3 lb/ton of steel melted. This level is somewhat higher than the lowest NOx level shown on RBLC for electric arc furnaces, but the proposed BACT level has been demonstrated by stack testing on a similar mill, whereas a demonstration is not readily available that the 0.2 lb/ton has actually been met in practice.' Based on the above, proposing a NOx limit for EAFs across the industry that is 45-55% lower than the limits from the LAER determinations has no technical basis, is stricter than any standard imposed by EPA under any program including LAER, and is not reasonable.

For Ladle/Tundish Preheaters, EPA is proposing a NOx emissions requirement of 0.06 lb/MMBTU. An RBLC search returns a LAER determination for Gerdau Macsteel Monroe (2018, RBLICID = MI-0438) with an emission limit of 0.08 lb/mmbtu (low NOx burners, use of NG fuel, and good combustion practices), which is above the 0.06 lb/mmbtu limit EPA is proposing. EPA's proposed NOx requirement for Ladle/Tundish Preheaters contradicts the 2021 Nucor Kankakee BACT determination and the 2018 Gerdau Macsteel Monroe LAER determination and has no technical basis.

For Reheat Furnaces, EPA is proposing a NOx emissions requirement of 0.05 lb/MMBTU. A search of the RBLC returns a RACT determination for Gerdau Sayreville Billet Reheat Furnace (2018, RBLCID = NJ-0087) with a NOx emission limit of 0.1 lb/mmbtu (low-NOx burners). Also, there are multiple types of reheat furnaces – billet, slab, walking beam, etc. It is not acceptable to group the reheat furnace types together and propose an emission limit that is 50% lower than the 2018 Gerdau Sayreville RACT determination. The Sterling Permit noted by EPA (Sterling Steel CO LLC (IL) 5/21/19 Construction Permit (Permit ID: 19020002) is for a new reheat furnace equipped with low-NOx natural gas-fired burners designed to emit no more than 0.073 lb of NOx/MMBTU to replace a reheat furnace that had reached end-of-life. It is not a retrofit of existing equipment. The permit states that the 'new reheat furnace will be more energy efficient than the existing furnace with less burner capacity than the existing unit.' It is not appropriate for EPA to propose a reheat furnace NOx emission limit based on a permit for new equipment/replacement in kind as most facilities would be looking at a retrofit of existing equipment.

For Vacuum Degassers, EPA is proposing a NOx emissions requirement of 0.03 lb/MMBTU, however, it is unclear why Vacuum Degasssers are included in this category at all. Vacuum Degassers themselves do not emit NOx, and any NOx emissions are only associated with the control device (flare) typically used as a control device for CO emissions from a Degasser. Also, in the RBLC the two facilities referenced by EPA, Nucor Darlington (RBLCID = SC-0197) and Nucor Tuscaloosa (RBLCID = AL-0275 and AL-0301) note that there is a flare used to control emissions; therefore, it is not reasonable for EPA to propose an industry-wide additional 40% NOx reduction by use of SCR without any demonstration that an SCR has or could be installed on a flare.

For Coke Ovens, EPA is proposing a NOx emissions requirement of 0.15 lb/ton (charging) and 0.015 lb/ton (pushing). A search of the RBLC indicates that the 0.019 lb/ton limit was a LAER determination (work practices) for Middletown Coke. EPA's proposed standard contradicts this LAER determination previously established by permitting authorities. Also, Middletown Coke is not part of the Iron and Steel and Ferroalloy Manufacturing industry as denoted by their 4-digit NAICS code (3241). Using an emission limit for units in a different industry that operate differently as the basis for Coke Ovens in the Iron and Steel and Ferroalloy Manufacturing industry is not appropriate.

<u>EXHIBIT D:</u>

Trinity Consultants

COMMENTS ON EPA'S PROPOSED GOOD NEIGHBOR FIP

Docket EPA-HQ-OAR-2021-0668

US Steel

Prepared By:

TRINITY CONSULTANTS

June 21, 2022

Project 223901.0025

TABLE OF CONTENTS

LIST OF TABLES

EPA proposed a federal implementation plan (FIP) at 87FR20036 on April 6, 2022 to address interstate transport of oxides of nitrogen (NO_X) via the "good neighbor" provisions of the Clean Air Act. The *Good Neighbor FIP* proposal is an extension of prior EPA rulemakings that established the Clean Air Interstate Rule (CAIR) and multiple versions of the Cross State Air Pollution Rule (CSAPR). The following comments reflect the collective comments of Trinity and U.S. Steel with an emphasis on the feasibility of the control technologies proposed by EPA for the iron and steel industry.

1.1 General Comments

First, EPA's proposed emission limits for the iron and steel is completely separated from the approach to the Good Neighbor rule that EPA explains in the preamble (see also Section 1.1.2).

> *The EPA notes that the types and sizes of the EGU and non-EGU sources that the EPA proposes to include in this proposed rule, as well as the types of emissions control technologies on which the EPA proposes to base the emissions limitations that would take effect for the 2026 ozone season, generally* ***are intended to be consistent with the scope and stringency of RACT requirements*** *for existing major sources of NO_X in downwind Moderate nonattainment areas and some upwind areas, which many states have already implemented in their SIPs.*
> 87FR20101-20102
>
> *The EPA recognizes that the numerous variables that contribute to differences in units' emissions rates may complicate development of limits for groups of units as large as those addressed in this proposed rule. For each emissions source category, the* ***EPA considered the range of emissions limits that currently apply to these sources under other CAA programs, such as RACT, NSPS, NESHAP, and OTC model rules, to develop an emissions limit that should be achievable by all sources after installing the controls identified in the Step 3 analysis.***
> 87FR20141
>
> *In developing the emissions limits for the Iron and Steel and Ferroalloy Manufacturing industry, the EPA reviewed RACT NO_X rules, NESHAP rules, air permits and related emissions tests, technical support documents, and consent decrees.*
> 87FR20145

The approach that EPA actually used in the proposed rule for the iron and steel industry is completely divorced from the stated rationale in the preamble. In the proposed rule:

- EPA started with the lowest emission rates identified in any prior RACT or BACT analysis
- EPA then applied additional reductions based on additional control technologies
- For iron and steel emission unit types other than annealing and reheat furnaces, the additional control technologies have never before applied to these emission units
- For most steel emission unit types other than annealing and reheat furnaces, EPA's references include no analysis of the feasibility of that control technology for that source type

For example, for annealing furnaces, EPA started with recent BACT determinations, and then applied an additional 40% reduction without any demonstration of achievability of the proposed limit. For blast furnaces, EPA started with an Ohio RACT limitation and then assumed a 50% reduction based on application of a control technology never before demonstrated to be feasible for this source type. EPA uses similar approaches for the proposed emission limits for all steel units in proposing emission limits far below those determined as either BACT or RACT in unit-specific analyses.

EPA appears to base its approach on an incorrect interpretation of the data in MCM and CoST and does not include any fact-based findings that these technologies can feasibly be implemented at the emission units in question. EPA had readily available fact-based steel specific analyses for these emission units that were completed in prior RACT, BACT, and BART determinations and yet ignored the fact-based determinations used to establish emission limits in those prior cases (see Section 1.2 for discussion of the fact-based unit-specific analyses previously completed by U. S. Steel, for example).

Second, the EPA rule development staff's apparent lack of knowledge or understanding of the iron and steel industry is illustrated throughout the proposed rule. For a vacuum degasser, NO_X is not generated in the process and so NO_X control cannot be applied there despite EPA's proposed control. And for an LMF, EPA proposes low NO_X burners as a control technology, but there are no burners in an LMF. If EPA wants to regulate NO_X from the steel industry, EPA must spend sufficient time to understand the process equipment and operations to develop an informed proposal rather than the current proposed rule.

Third, EPA does not provide actual citations or references to support most of the emission limits and proposed control technologies in the rules. As documented on a unit-specific basis in Section 1.2 as well as in Section 1.1.3, EPA does not include critical reference material in the docket for the rule, such that the regulated community cannot meaningfully review the proposed conditions.

Fourth, the proposed rule has numerous errors and inconsistencies. For example, the proposed rule suggests that the steel industry is subject to a 3-hour average in one location, and a 30-day rolling average in another location; the degree of stringency between a 3-hour and a 30-day average emission limit is well understood by EPA (see discussions in rulemakings for NSPS Subparts Da and Db for example). EPA also specifies applicability of the proposed rule in one location as any two units which combined exceed a PTE of 100 tpy, and in another location specifies applicability as on individual units over 100 tpy except in the BOF Shop, where emission units are added for applicability; again, the impact of the proposed rule will be substantially different depending on which applicability requirement applies.

1.1.1 EPA ignores stated control approach of RACT and does not justify its deviation from RACT

In all prior rulemakings for ozone transport, EPA has emphasized that the levels of emissions controls being required for EGUs was consistent with RACT. EPA has stated that the same approach is the underpinning for this present proposal.

> *The EPA notes that the types and sizes of the EGU and non-EGU sources that the EPA proposes to include in this proposed rule, as well as the types of emissions control technologies on which the EPA proposes to base the emissions limitations that would take effect for the 2026 ozone season, generally* ***are intended to be consistent with the scope and stringency of RACT requirements*** *for existing major sources of* NO_X *in downwind Moderate nonattainment areas and some upwind areas, which many states have already implemented in their SIPs.*
> 87FR20101-20102 [emphasis added]

The approach that EPA actually used in the proposed rule for the iron and steel industry is completely divorced from the stated rationale in the preamble and is more stringent than best available control technology (BACT)[1] or even lowest achievable emission rate (LAER)[2]. In the proposed rule, EPA started with the lowest emission rates identified in any prior RACT or BACT analysis, and then applied additional reductions, often based on control technologies never before applied to these emission units based on incorrect generic assumptions about viability without any support technical justification. For example, for annealing furnaces, EPA started with recent BACT determinations, and then applied an additional 40% reduction without any demonstration of achievability of the proposed limit. For blast furnaces, EPA started with an Ohio RACT limitation and then assumed a 50% reduction based on application of a control technology never before applied to this source type.

EPA uses similar approaches for the proposed emission limits for all steel units in proposing emission limits far below those determined as either BACT or RACT in unit-specific analyses. EPA never explains a rationale for deviating from RACT or BACT.[3]

> *Reasonably available control technology (RACT) means devices, systems, process modifications, or other apparatus or techniques that are reasonably available taking into account:*
>
> *(1) The necessity of imposing such controls in order to attain and maintain a national ambient air quality standard;*
>
> *(2) The social, environmental, and economic impact of such controls*
>
> [40 CFR 51.100(o)]

EPA's methodology in the proposed rule has significant flaws.

- BACT is a more stringent control level than RACT, and as such, by starting with BACT analyses, EPA is already selecting a control level that is more stringent than the stated rationale in the proposal preamble
- Compounding the first flaw, EPA then applies additional speculative reductions to each identified lowest emissions limits for each unit type, without any justification about the relevance of that control technology to the unit, nor any assessment of the percent control that may be achievable by that control

---

1 *Best available control technology means an emissions limitation (including a visible emission standard) based on the maximum degree of reduction for each pollutant subject to regulation under the Act which would be emitted from any proposed major stationary source or major modification which the Administrator, on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines is achievable for such source or modification* …
[40 CFR 52.21(b)(12)]

2 *Lowest achievable emission rate (LAER) means, for any source, the more stringent rate of emissions based on the following:*
(A) The most stringent emissions limitation which is contained in the implementation plan of any State for such class or category of stationary source, unless the owner or operator of the proposed stationary source demonstrates that such limitations are not achievable; or
(B) The most stringent emissions limitation which is achieved in practice by such class or category of stationary sources. This limitation, when applied to a modification, means the lowest achievable emissions rate for the new or modified emissions units within or stationary source. In no event shall the application of the term permit a proposed new or modified stationary source to emit any pollutant in excess of the amount allowable under an applicable new source standard of performance.
[40 CFR 51.165(a)(1)(xiii)]

3 The CoST/MCM has limited and generally poor data for the iron and steel industry. It appears that EPA incorrectly used CoST/MCM in a manner inconsistent with the referenced studies and documents on which CoST/MCM are based, and then attempted to "find" the reductions that CoST/MCM suggested may be available.

technology. Further, EPA is arbitrarily taking the lowest emission limit from the range of baseline NOx limits and applying the maximum percent reduction of the provided % NOx reduction efficiency range.

- EPA's method (and resulting emission limits for the iron and steel industry is actually more stringent than LAER. LAER is the lower of the most stringent limitation identified for a type of emission unit, or the lowest rate achieved in practice. EPA has not demonstrated that the emission rates in the proposed rule have been achieved in practice or are otherwise feasible, and the proposed rates are more stringent than any cited SIP emission limits.

1.1.2 EPA's apparent reliance on MCM and CoST to identify emissions control options for the steel industry is flawed

Nowhere in the preamble nor the rule docket does EPA identify a specific rationale regarding how EPA determined the applicability of a control technology to an emissions unit, nor how EPA determined what emissions reduction could be achieved on a unit. However, how EPA actually used MCM and CoST is deeply flawed.

As one example, for a blast furnace, EPA makes two statements in explaining the derivation of the proposed limit.

> *OH NO_X RACT rules limit NO_X emissions from blast furnaces to 0.06 lb/ mmBtu without requiring specific control technology. Control NO_X at stoves (typically 3 or 4 per blast furnace), assuming 40–50% reduction) by burner replacement plus SCR.*
> [87FR20145]
>
> *In setting a NO_X emission limit for blast furnaces, EPA considered a range of emission rates from 0.02 lb/mmBtu to 0.05 lb/mmBtu as calculated based on potential use of low-NOx burners, flue gas recirculation, and SCR. EPA notes that it has approved an Ohio SIP rule of 0.06 lb/mmBtu without specifically requiring use of NOx-reducing control technology. See OAC 3745-110-03(N). Use of these technologies separately or in combination can achieve 20-90% reduction efficiency at blast furnace stoves. In this rulemaking, EPA is requiring each facility to tailor its NOx reduction technology to meet a NOx limit of 0.03 lb/mmBtu.*
> [Non-EGU TSD]

So, EPA suggests that three control technologies are applicable here (low NO_X burners, FGR, and SCR) and stating that 20-90% NO_X reduction is achievable at blast furnace stoves using those technologies before proposing a 50% reduction on top of the Ohio NO_X RACT limit.

Despite being critical in supporting a proposed emission limit:

- EPA never states the basis for identifying that those three control technologies are applicable to blast furnaces
- EPA provides no explanation of why those measures are technically feasible for this application
- EPA provides no explanation of the impact on firing BFG versus natural gas versus a blend
- EPA provides no explanation regarding what reductions could be expected for a blast furnace,

From review of the non-EGU TSD, we infer that EPA is using the Menu of Control Measures (MCM) and the related Control Measures Database (CMDB) as reference sources for potential control technologies, as well as for cost effectiveness of potential control technologies.[4]

In connection with the preparation of these comments, Trinity downloaded the MCM section for iron and steel industry and reviewed both the MCM table entries as well as the cited references for the MCM; doing so required emails and phone calls to EPA staff quoted in the references to obtain files which are not in the rulemaking docket. Trinity also downloaded the Control Strategies Tool (CoST) and extracted the underlying data in the tool for steel, including the references.[5] Trinity also reviewed the CMDB.

Based on the review of these three sources, it is clear that CoST, MCM and CMDB rely upon the same input data sources to project potential control options and related control costs for the iron and steel industry. Trinity traced the iron and steel industry data listed in both MCM and CoST to the underlying cited reference files. Table 1 is a table showing the MCM and CoST references as well as the related steel references from EPA's non-EGU TSD. Table 1 also shows whether or not a reference was included in the docket for this proposed rule and whether or not Trinity was able to obtain references not included in the docket.

Most of the reference files cited for MCM and CoST are re-compilations of earlier data. Based on Trinity's review of available files (either from the docket or obtained by Trinity during this review), the following documents are the most relevant ones for the iron and steel industry, listed by date. Summaries of these four documents are provided in Appendix A.

- EPA 1994e
  - A steel-specific analysis
  - U.S. Environmental Protection Agency, Emissions Standard Division, Office of Air Quality Planning and Standards, "Alternative Control Techniques Document-- NOx Emissions from Iron and Steel Mills," EPA-453/R-94-065, Research Triangle Park, NC, September 1994.

- EPA 1998e
  - A first attempt by EPA at assessing non-EGUs with respect to ozone
  - Pechan, 1998: E.H. Pechan & Associates, Inc., "Ozone Transport Rulemaking Non-Electricity Generating Unit Cost Analysis," prepared for U.S. Environmental Protection Agency, Office of Air Quality Planning and Standards, Innovative Strategies and Economics Group, Research Triangle Park, September 1998.

- Non-EGU TSD Reference 44
  - Cited as an input to EPA2010b
  - Midwest Regional Planning Organization (MRPO). 2005. Iron and Steel Mills Best Available Retrofit Technology (BART) Engineering Analysis, prepared by MACTEC

- EPA 2010b
  - The most recent steel-specific analysis by EPA
  - EPA, 2010: "NO_X CONTROL STRATEGIES IN THE IRON AND STEEL INDUSTRY (11-11-10).pdf", pdf document provided by Donnalee Jones (jones.donnalee@epamail.epa.gov) via email to Amy Vasu 11/16/10.
  - Trinity obtained two related additional files from EPA as part of our search for references
    - The 1994 Alternative Control Techniques document mentioned above
    - NO_X Control Technology from Iron and Steel Plants-05-03-10-send.pdf, which appears to be a peer review of the EPA 2010b document.

Among the documents, only two perform any analysis regarding steel industry units, (1) EPA 1994e, the 1994 Alternative Control Techniques (ACT) document, and (2) Non-EGU TSD Reference 44, the 2005 MRPO BART analysis. In contrast, EPA 1998e and EPA 2010b are data compilations but without any iron and steel industry unit analysis; each of EPA 1998e and EPA 2010b appear to be used by EPA to transfer data from the 1994 ACT and 2005 MRPO documents into EPA's MCM and CoST tools.

Critically important, the 1994 ACT and 2005 MRPO documents only assess NO_X emissions controls for reheat furnaces and annealing furnaces. Thus, the underlying studies for CoST only address two of the steel unit types proposed to be regulated in this EPA action. <u>As such, there is no basis in EPA's inclusion of emission limits for numerous other iron and steel emission units based on CoST and MCM, when CoST and MCM only have input data for annealing and reheat furnaces.</u>

1.1.3 The docket does not include critical reference files, and EPA must provide all references used in the docket in a future re-proposal

Based on statements in the preamble and the non-EGU TSD, EPA erroneously relied upon data compilations in MCM and CoST in determining that emissions reductions are available and cost effective from the iron and steel industry. However, MCM and CoST are simply compilations of other data sources, where the data for each control type and cost for process equipment are cited to an underlying document. Neither MCM nor CoST directly include explanations for how the included data are appropriate. As such, the underlying documents are critical to assessing the validity of the data.

Because EPA uses MCM and CoST as the basis for establishing the cost-effective emissions from the iron and steel industry (where cost effective reductions are those that EPA defines as contributing significantly), the accuracy of the underlying data is critical for a source to review the reasonableness of EPA's proposal.

As shown in Table 1, numerous key references in MCM, CoST and the non-EGU TSD were not included in the docket, and while Trinity was able to obtain some of the references that were sought, there were several which Trinity was not able to obtain, even in cases where the person cited in the reference was reached.

Beyond just MCM/CoST, there are other critical citations and/or documents not provided as part of the proposal for specific emission units. For example, for the EAF, EPA generically defines the baseline emissions as being based on comparison to existing permit limits for EAFs, without citing specific emission units and permit conditions. For coke oven charging, EPA references an apparently non-existent AP-42 emission factor but does not provide a citation. Where EPA is using a document as the basis for a proposed limit or condition, EPA must specifically identify the document and provide that document in the docket.

Due to the EPA not providing reference documents available for review, and due EPA's lack of citations/specificity in the basis for emissions limits, neither Trinity nor U. S. Steel cannot complete a thorough analysis.

1.1.4 EPA's cost estimates inaccurately assume year-round operation of control devices resulting in improperly low cost-effectiveness values

EPA's cost-per-ton reduction calculations are low because they assume that SCR will be run all year at facilities that install it and calculates expected cost per ton on the basis of annual tons of NOx reduced, despite the fact that the NOx emission reductions being sought by EPA in the Proposed Rule are only to address ozone season emissions. For instance, EPA estimates that selection of SCR in the iron and steel industry may be associated with 948 tons ozone season NO_X reductions, at an annual cost of $9,886,092. If EPA had calculated the cost per ozone season ton of NO_X reduced, this would result in a cost threshold estimate of $10,428 per ton of NO_X reduced[6], which is well above the cost threshold of $7,500 stated by EPA in the proposed rule). But EPA instead, lists the average cost per ton reduced as $4,345, which would only be the case if the ozone season tons were extrapolated to assume continuous annual reductions.[7]

While calculating cost effectiveness on an annual basis for comparisons can be appropriate, the correct cost basis for the proposed rule is on the ozone season. Under the proposed rule, EPA only has authority to reduce ozone season emissions and thus should limit itself to assessing the cost of ozone season reductions.

Additionally, as a practical matter, facilities will not operate SCR during the non-ozone season as EPA has acknowledged in the proposed rule to be "quite typical" in the context of EGUs. There are sound technical and economic reasons for not operating SCR outside the ozone season, due to the O&M cost associated with operation of the SCR. When comparing cost estimates to the $7,500/ton screening threshold set by EPA, the values must be compared on an ozone season basis.

---

6 $9,886,092 / 948 ton = $10,428/ton

7 $9,886,092 / [12/5)*948 tons] = $9,886,092 / 2,275 tons = $4,345/ton

1.1.5 EPA's reliance on screening-quality emissions control data from CoST and MCM leads EPA to an incorrect conclusion on available reductions, and thus significant contribution

As noted in Section 6.1.1, EPA determined that emissions that could be removed below a certain cost threshold are those emissions which contribute significantly, regardless of the relative contribution by a state to a receptor. EPA then used CoST, MCM and the Control Measures Database (CMDB) to determine the emissions that could be removed based on theoretical application of SCR, SNCR and burner replacement.

> *Due to the many types of units within Iron and Steel Mills and Ferroalloy Manufacturing facilities that are not currently subject to NO_X limitations of the stringency necessary to eliminate significant contribution, most of the emissions limits in this proposed rule are based on examples of permitted emissions and estimated reduction potential from the identified control technology. Based on the selection of SCR, SNCR, and burner replacement in the non-EGU screening assessment, the EPA assumed reductions of 20 to 50 percent from current permitted limits and emissions tests depending on the type of unit and controls being implemented.*
> [87FR20146]

Note the key reliance on CoST, MCM and CMDB estimates, which are at best screening quality.

- In the quote above, EPA first states that units in the iron and steel industry are not subject to NO_X limitations sufficiently stringent to eliminate significant contribution.
- EPA has already stated that "significant contribution" is determined based on cost-effective reductions being available and EPA's discussion regarding Step 3.[8]
- To determine those cost-effective reductions are available, EPA relied upon CoST, as when a CoST model run was completed, the CoST modeling showed that emission reductions are available in the steel industry that are cost effective
- Upon the CoST run showing that cost effective reductions are available in steel, EPA then relied upon CoST/MCM/CMDB to identify potential control technologies that could be applied to the steel industry units
- Lastly, EPA appears to have arbitrarily selected % reductions from the lowest identifiable emissions rate for a steel unit based on some unstated attribution to a mix of add-on controls identified by MCM as being applicable (see Table 2)

EPA also made assumptions about the types of emission units at which the control technologies were feasible without any stated basis. None of the underlying technical analyses support add-on pollution control on any steel sources other than annealing furnaces, while the proposed rule covers numerous additional steel emissions units. Trinity infers that EPA may have been misled by data in CoST and MCM regarding the applicability of the control measures.

[8] As per 87FR20055, *the EPA selected the technology breakpoint (represented by a cost threshold) that, in general, maximized cost-effectiveness—i.e., that achieved a reasonable balance of incremental NOX reduction potential and corresponding downwind ozone air quality improvements, relative to the other emissions budget levels evaluated. See, e.g., 81 FR 74550. The EPA determined the level of emissions reductions associated with that level of control stringency to constitute significant contribution to nonattainment or interfere with maintenance of a NAAQS downwind.*

Moreover, EPA never attempts to justify why case-specific recent BACT and RACT determinations (cited as the basis for the lowest identifiable emission rates) are not more reliable and accurate than screening level, generic data from CoST and MCM.

Table 2 summarizes EPA's proposed steel unit emission limits, as well as EPA's stated rationale for the limits from both the rule preamble as well as from the non-EGU TSD. The non-EGU TSD references MCM as the basis for the potential control percentages, and the preamble references CoST, but since MCM and CoST have largely the same underlying references the distinction in MCM versus CoST is minor.

EPA correctly notes the limitations of CoST in a footnote to Table IX-2 in the proposal (87FR20157), but then ignores this critical caveat in the proposed rule.

> *CoST is designed to be used for illustrative control strategy analyses (e.g., NAAQS regulatory impact analyses) and not for unit-specific, detailed engineering analyses. The estimates from CoST identify proxies for (1) non-EGU emissions units that have emissions reduction potential, (2) potential controls for and emissions reductions from these emissions units, and (3) control costs from the potential controls on these emissions units. … This screening assessment is not intended to be, nor take the place of, a unit-specific detailed engineering analysis that fully evaluates the feasibility of retrofits for the emissions units, potential controls, and related costs.*
