The author of the footnote to Table IX-2 understood the limitations of using CoST (which in turn relies upon both MCM and CMDB). However, in the proposed requirements, EPA ignores the limitations of CoST. In the proposed rule, EPA presumes that CoST is accurate and applicable to each and every steel emissions unit, without any consideration of a feasibility assessment or any engineering.

Table 2. EPA assumptions underlying proposed steel limits

Emissions Unit	Proposed Limit	Units	Add-On	% Reduction	EPA Basis from Preamble	EPA Basis from non-EGU TSD
Blast Furnace	0.03	lb/ MMBtu	Burner replacement/ SCR	50%	OH NOX RACT rules limit NOX emissions from blast furnaces to 0.06 lb/ mmBtu without requiring specific control technology. Control NOX at stoves (typically 3 or 4 per blast furnace), assuming 40–50% reduction) by burner replacement plus SCR.	In setting a NOx emission limit for blast furnaces, EPA considered a range of emission rates from 0.02 lb/mmBtu to 0.05 lb/mmBtu as calculated based on potential use of low-NOx burners, flue gas recirculation, and SCR. EPA notes that it has approved an Ohio SIP rule of 0.06 lb/mmBtu without specifically requiring use of NOx-reducing control technology. See OAC 3745-110-03(N). Use of these technologies separately or in combination can achieve 20-90% reduction efficiency at blast furnace stoves. In this rulemaking, EPA is requiring each facility to tailor its NOx reduction technology to meet a NOx limit of 0.03 lb/mmBtu.
Basic Oxygen Furnace	0.07	lb/ton	SCR/SNCR	50%	Potential 25–50% reduction by SCR/SNCR from 0.14 lb/ton based on emissions testing.	For basic oxygen furnaces, EPA based the emission limit of 0.07 lb/ton of steel on performance testing data from basic oxygen furnaces without NOx reduction controls at integrated iron and steel mills in the United States. EPA projects minimally 50% NOx reduction efficiency is achievable by use of low-NOx technology, including potential use of FGR and selective catalytic reduction. Most BOF vessels and associated BOF Shops in the United States are equipped with capture technology and existing particulate matter control devices. The existing configurations of these shops would accommodate the addition of NOx controls or additional design of a capture system capable of integrating such technology with these structures.
Electric Arc Furnace	0.15	lb/ton steel	SCR	25%	Example permit limits at around 0.2 lb/ton. Assumes 25% reduction by SCR to achieve 0.15 lb/ton steel.	For EAFs, EPA based the emission limit of 0.15 lb/ton of steel on projected reduction efficiency of 40-50% as compared to existing permit limits for EAFs. EPA considered a range of baseline emission data and permit limits from mini mills, integrated iron and steel facilities, and ferroalloy facilities ranging from 0.20 lb/ton to 0.35 lb/ton. EPA projects minimally 40% NOx reduction efficiency is achievable by use of low-NOx technology, including potential use of low-NOx burners and selective catalytic reduction.
Ladle/tundish Preheaters	0.06	lb/ MMBtu	SCR	40%	Nucor Kankakee BACT permit limit issued January 2021 is 0.1 lb/mmBtu, 2021. Assume 40% reduction by SCR.	For ladle and tundish preheaters, EPA based the emission limit of 0.06 lb/mmBtu on existing permit limits. The majority of recently issued permits limit NOx emissions from ladle and tundish preheaters to 0.1 lb/mmBtu based on prevailing operating rates compared to natural gas usage. EPA projects minimally 40% NOx reduction efficiency is achievable by use of low-NOx technology, including potential use of low-NOx burners and selective catalytic reduction.
Reheat furnace	0.05	lb/ MMBtu	SCR	40%	Sterling Steel permit, issued 2019: Low-NOX natural gas fired burners de- signed to emit no more than 0.073 lb NOX/mmBtu, Ohio RACT limit is 0.09 lb/mmBtu. Assume 40% reduction by SCR.	For reheat furnaces, EPA based the emission limit of 0.05 lb/mmBtu on projected reduction efficiency of 40-50% based on sampled operating and emission rates compared to natural gas usage. EPA projects minimally 40% NOx reduction efficiency is achievable by use of low-NOx technology, including potential use of newer generation low-NOx burners or optimization of existing burners.
Annealing Furnace	0.06	lb/ MMBtu	SCR	40%	Big River Steel (AR) 2018 limit and Benteler Steel (LA) 2019 limit (0.11 lb/ mmBtu), 85 mmBtu/hr and 13 mmBtu/hr, respectively. Lowest was 0.0915 lb/mmBtu, Nucor AR. Assume 40% reduction by SCR.	For annealing furnaces, EPA based the emission limit of 0.06 lb/mmBtu on projected reduction efficiency of 40-50% based on current permit emission limits and operating rates compared to natural gas usage. EPA projects minimally 40% NOx reduction efficiency is achievable by use of low-NOx technology, including potential use of newer generation low-NOx burners or optimization of existing burners, or combination of low-NOx burners, flue gas recirculation, and/or selective catalytic reduction.
Vacuum Degasser	0.03	lb/ MMBtu	SCR	40%	0.05 lb/mmBtu Nucor Darlington (SC) and Nucor Tuscaloosa (AL). Assume 40% reduction by SCR.	For vacuum degassers utilized in secondary steelmaking, EPA based the limit of 0.03 lb/mmBtu on existing permit limits of 0.05 lb/mmBtu. EPA projects minimally 40% NOx reduction efficiency is achievable by use of low-NOx technology, including use of selective catalytic reduction.
Ladle Metallurgy Furnace	0.1	lb/ton	SCR	40%	Assume 40% reduction by SCR.	For LMFs, EPA based the emission limit of 0.1 lb/ton of steel on projected reduction efficiency of 40-50% as compared to existing permit limits for LMFs. EPA considered a range of baseline emission data and current permit limits from 0.20 lb/ton to 0.35 lb/ton. EPA projects minimally 40% NOx reduction efficiency is achievable by use of low-NOx technology, including potential use of low-NOx burners and selective catalytic reduction.
Taconite Production Kilns	tice, low NOx burners				Consistent with requirements in Minnesota Taconite FIP See 81 FR 21671.	
Coke Ovens (charging)	0.15	lb/ton of coal charged	Staged combustion SCR/SNCR	50%	Assume 50% reduction staged combustion and/or limited use SCR/SNCR during charging operations from AP–42 0.3 lb/ton emission factor.	For coke ovens (charging) and coke ovens (pushing), EPA based the emission limit of 0.15 lb/ton for charging and 0.015 lb/ton for pushing on projected reduction efficiency of 40-50% based on current permit emission limits and production-based push/charge cycles. EPA projects minimally 40% NOx reduction efficiency is achievable by use of low-NOx practices, staged pushing and hood configurations, and potential use of add-on NOx control technology at larry cars and pushing/charging machines, including potential use of low-NOx burners, flue gas recirculation, and/or the addition of selective catalytic reduction to mobile hoods and particulate matter control devices.
Coke Ovens (pushing)	0.015	lb/ton of coal pushed	SCR	25%	SunCoke Middletown limit is 0.02 lb/ton of coal. Assume 25% reduction by SCR.	

1.1.6 The lack of a trading option makes EPA's errors in setting unit-specific emission limits critical

In prior Good Neighbor rulemakings focused on EGUs, EPA has had reasonably accurate cost estimates for emissions control for EGUs in the aggregate. For EGUs, as long as EPA is reasonably accurate, the availability of an emissions trading program provides unit-specific flexibility. If a control technology at a particular unit is much more expensive, that unit has the option to buy allowances and comply with the regulations. Or, alternatively and more likely, a company may choose to over control one source that is more cost effective to generate allowances for another source that is less cost effective.

For two reasons, EPA's approach with non-EGUs suffers critical flaws. First, as already explained earlier in this section, EPA's cost estimates are screening level only, and it appears that EPA selected the lowest published cost estimates from the available studies (with no stated basis for that selection); that in itself brings question on EPA's proposed emission limits.

Because each emissions unit must meet a specific emissions limit, with no opportunity to trade allowances either within the company or in the greater market, the accuracy of the cost estimates becomes a critical factor. Unquestionably EPA's cost estimates are inaccurate for the proposed emissions sources, and unquestionably as proposed each unit must meet a specific emissions limit based on screening, highly caveated analysis, where that analysis has zero technical foundation for emission units other than reheat and annealing furnaces.

1.1.7 EPA has incorrectly applied its own data to a determination of the cost threshold to evaluate emission reductions related to Tier 1 industries

As noted earlier, there are numerous problems with the assumptions in EPA's CoST model with respect to the steel industry. Beyond those problems, EPA incorrectly applied its own CoST output data regarding emissions reductions from Tier 1 industries.

In EPA's Screening Assessment for Non-EGU Emissions Units, EPA states the following:

> *To identify an annual cost threshold for evaluating potential emissions reductions in the Tier 1 and Tier 2 industries, the EPA used the Control Strategy Tool (CoST), the Control Measures Database (CMDB), and the projected 2023 emissions inventory to prepare a listing of potential control measures, and costs, applied to non-EGU emissions units in the projected 2023 emissions inventory. Using this data, we plotted curves for Tier 1 industries, Tier 2 industries, Tier 1 and 2 industries, and all industries at $500 per ton increments. Figure 1 indicates there is a "knee in the curve" at approximately $7,500 per ton. We used this marginal cost threshold to further assess estimated emissions reductions, air quality improvements, and costs from the potentially impactful industries. Note that controls and related emissions reductions are available at several estimated cost levels up to the $7,500 per ton threshold. The costs do not include monitoring, recordkeeping, reporting, or testing costs.*

A review of Figure 1 in the document shows that that Tier 1 Industries have a very much lower marginal cost threshold than the $7,500 per ton value assigned to Tier 1 Industries by EPA. Indeed, as is graphically illustrated in Figure 1, the knee in the curve for Tier 1 sources occurs at a cost of approximately $1,000 per ton at which point the ozone season NO_X reduction potential is in excess of 50,000 tons. Increasing the cost threshold to $7,500 per ton (approximately a 700% increase in cost) does nothing more than increase the

Tier 1 NO_X reduction potential by approximately 15% more than would be achieved at the $1,000 per ton threshold. The CoST model is showing is that nearly all available reductions at Tier 1 industries are at the $1,000/ton level; based on review by Trinity of the CoST inputs for the steel industry, CoST reductions at less than $1,000/ton correlate only to combustion improvements like low NO_X burners, and not to post-combustion controls like SCR.[9]

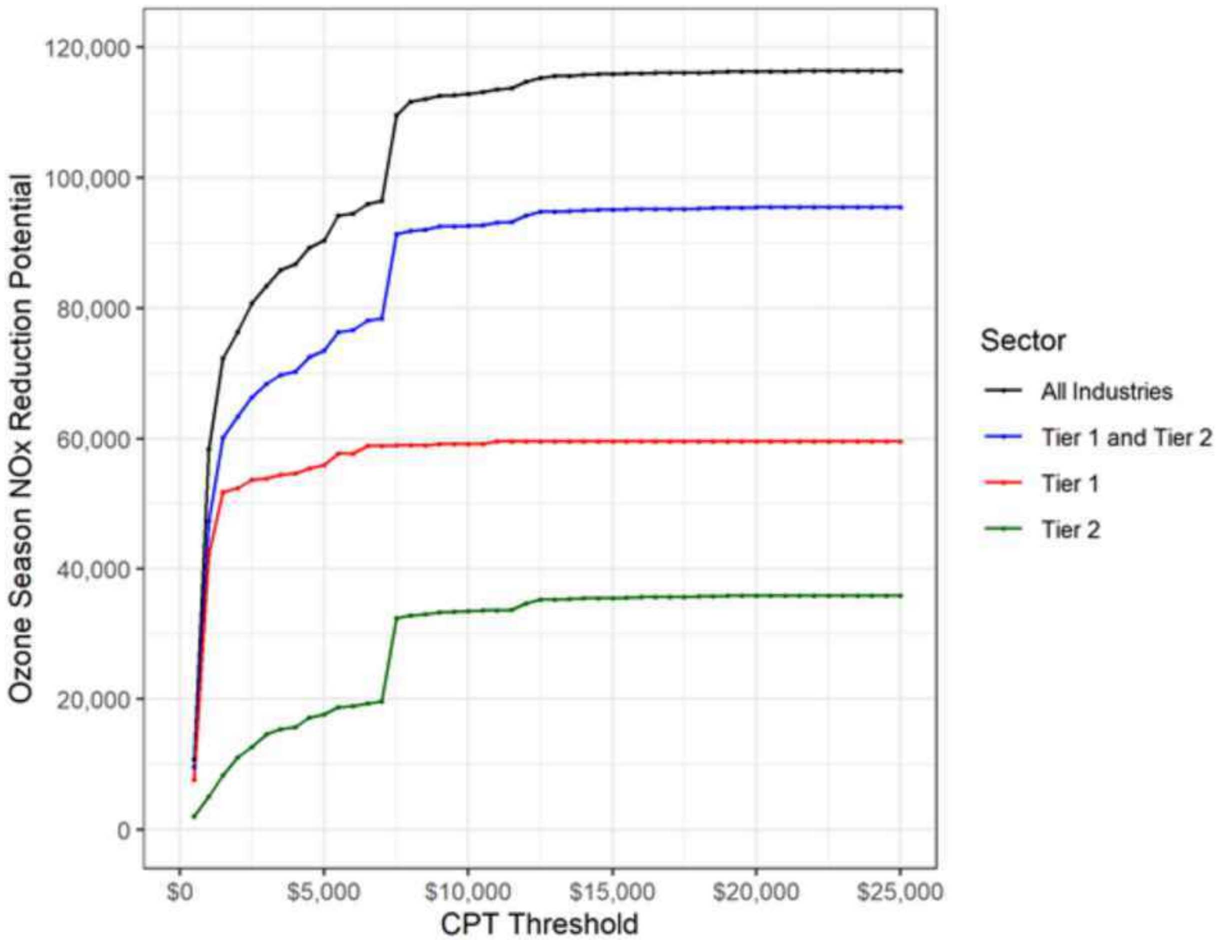
In prior rulemakings, EPA has emphasized the importance of identifying the knee in the curve to optimize cost efficiency. In the present rulemaking, EPA discusses exactly this topic in the context of not increasing the cost threshold for EGU control costs.

> *Emissions reductions from these measures are relatively small and would entail much higher dollar per ton costs, going beyond what is widely observed in the fleet. Although these additional measures are not included in EPA's technology breakpoint analysis discussed above, the EPA did examine the cost, potential reductions, and air quality impact of these additional measures in a supplemental analysis to affirm that they do not merit inclusion in the proposed stringency for this action. Similar to prior rules, there is a notable "knee-in-the-curve" breakpoint if these additional measures are included in EPA's analysis. In other words, there are very little additional emissions reductions and air quality improvement at problematic receptors, and the cost associated with these measures increases substantially on a dollar per ton basis.* [87FR20095]

The exact case that EPA describes here for EGUs applies to Tier 1 non-EGUs when extending the $/ton threshold beyond approximately $1,000/ton: based on CoST predictions, minimal additional emission reductions are obtained from Tier 1 industries going beyond $1,000/ton, and yet costs increase substantially.

[9] While SCR is not a post-combustion control as applied to an EAF and other emission units in the iron and industry industry where NOx emission are not generated by combustion of fossil fuels, we refer to them here as post-combustion controls because that his how EPA refers to SCR and other technologies in the proposed rule.

Figure 1. Ozone Season NOx Reductions and Costs per Ton (CPT) for Tier 1, Tier 2 Industries, and Other Industries



1.2 Analysis of Feasibility of Proposed Limits and Theoretical Controls

As discussed in more detail below, EPA has failed to demonstrate that the proposed emission limits for the iron and steel industry and theoretical controls in the proposed rule are technically feasible.

1.2.1 Blast furnaces

1.2.1.1 Description

Blast furnaces (BFs) are used to convert iron ore and iron-bearing raw materials to hot metal. The process is completed in a vertical shell blast furnaces in which raw materials (ore, coke, and flux) are introduced at the top of the furnace and hot blast air, oxygen and either natural gas, pulverized coal or coke oven gas are injected at the bottom of the furnace to generate heat and melt the iron by removing the oxides to form metallic iron.

To provide the hot blast air, the furnaces are equipped with regenerative heat exchangers (stoves) in which the blast air is preheated. Blast furnace gas (BFG) and natural gas (and if available cleaned desulfurized coke oven gas (COG)) are fired in the stoves to heat the stove refractory. When the required temperature is achieved the gas flow is reversed and the stored sensible heat is recovered into the blast air. Typically, there are 3 to 4 stoves (dependent on age and design) on each blast furnace which allows a continuous and even blast air temperature with one common exhaust stack per set of stoves; note that the stove stack exhaust is separate and distinct from the off-gases produced from the iron-making process in the blast furnaces.

Combustion of BFG, in general, but in particular on the stoves, requires a high volume of combustion air due to a significant percentage of inert gases in the BFG (CO_2, N_2). The combustion produces thermal NO_X, but the reaction is suppressed by the presence of CO in the combustion flame and emits much less thermal NO_X than does natural gas combustion (COG emits thermal NO_X at a rate between that of BFG and natural gas). As in all combustion reactions excess oxygen and flame temperature determine NO_X formation, and the BFG with smaller heating value, approximately 1/10 of natural gas, burns at relatively low adiabatic flame temperature.

Typical stoves have exhaust temperatures in the 350-500 °F range, with emission rates already in less than typical low NO_X emission rates for boilers.

1.2.1.2 Potential for NO_X Reduction

NO_X reductions could be achieved on a blast furnace process in the event any of the following technologies were technically or economically feasible

1. Use of lower NO_X burners in the stove heating system.
2. Installation of selective catalytic reduction (SCR) in the stove stack(s).
3. Flue gas recirculation.
4. Selective non-catalytic reduction (SNCR) in the stove stacks .

U. S. Steel evaluated RACT for blast furnace stoves at Edgar Thomson in a report by AMEC Environmental and Infrastructure dated April 1, 2014. The analysis at this site is representative of blast furnace stoves in the U. S. Steel fleet.

The 2014 RACT analysis found the following:

- Units were achieving NO_X emission rates of less than low NO_X emission rates for boilers

- Flue gas recirculation (FGR) is not technically feasible since blast air cannot be recycled from the blast furnace and air flow during initial heating of the stoves is based on natural convection

- SCR
  - Determined to be technically infeasible due to the changing direction of the air flow, such that there are substantial temperature swings as a stove switches from heat to blast and back.
  - Determined to cost from $75,533/ton to $124,972/ton assuming for the sake of argument that SCR was actually technically feasible
- SNCR
  - Technically infeasible like SCR due to temperature swings
  - More costly than SCR at $426,000/ton to $678,001/ton

U. S. Steel also evaluated BART for blast furnace stoves at Gary Works in a September 25, 2020 analysis by Barr. That analysis found that no add-on technology was BART for the stoves, and that BFG was already a low NO_X fuel

1.2.1.3 EPA's Proposed Emission Limit for Blast Furnaces is Not Feasible

- EPA's assumption of a 50% reduction in NOx emissions from blast furnaces using add on-control technologies is not supported by any technical analysis for blast furnace stoves
- There is no technical analysis in the docket or in references used as the basis for CoST and MCM for blast furnace stoves.
- EPA has erroneously found that cost-effective emission reductions are available at blast furnace stoves by misusing the EPA CoST model
- EPA incorrectly assumes that SCR is applicable to blast furnace stoves despite any support in the docket
- The underlying EPA SCR cost estimates for iron and steel units only have any basis for annealing and reheat, where costs are developed in the 2005 MRPO BART document
- EPA's CoST model only cites two bases for SCR costs for steel process units $7,020 (2016$) for SCR for an annealing furnace, and $6,599 (2016$) for coke oven gas in-process combustion (by citing here, Trinity and U. S. Steel do not concur that EPA's CoST model SCR costs are correct)
  - The annealing estimate is cited on #280, #283, #285, #287, #289 and #304
  - The coke oven gas estimate is cited as #205 and #277 (discussed above)
    - #280 is a 2007 regulatory impact analysis that did not perform a cost estimate specific to steel units but instead used standard CoST/MCM/CMDB data in a screening analysis for non-EGU emissions
    - #283 is the EPA Control Cost Manual that only instructs how to perform economic calculations
    - #285 is about SCR costs on coal-fired boilers
    - #287 was not obtainable despite contact with to the EPA
    - #289 is an analysis performed as part of the NO_X SIP Call that first attempted to assess non-EGU impacts, but did not perform any analyses specific to steel units

- #304 is an EPA document about process heaters overall, focusing on chemical and petroleum refining, with no analysis of steel process heaters and no analysis of the BFG or COG
- The only underlying studies that attempted to calculate steel costs for SCR are the 1994 ACT study and the 2005 MRPO study
- The 2005 MRPO study values (in 2005$) for SCR range from $7,566-$13,762 for annealing furnaces, with numerous caveats about the generic assumptions and how site-specific variations could result in substantial cost or feasibility differences
- The EPA CoST model lists a cost (in 2016$) for SCR of $7,020 for annealing furnaces and $6,599 for coke oven gas. These values are below the lowest value from the 2005 MRPO study, prior to adjusting the 2005 MRPO values to adjust to 2016$.
- Annealing and reheat furnaces are vastly different processes than blast furnace stoves.
- Overall, the $/ton cost effectiveness values for SCR for iron and steel emission units in the CoST model are not credible and not supported by the underlying reference documents

1.2.2 Basic Oxygen Furnace

1.2.2.1 Description

Basic oxygen furnaces (BOFs) are used in integrated iron and steel facilities to convert hot metal produced in the blast furnace and scrap to steel. In order to convert the hot metal to steel, the carbon in the hot metal is removed by oxidation in the BOF vessel. This process is completed by blowing oxygen into the liquid metal bath forming carbon monoxide (CO) and carbon dioxide (CO_2) and slag by the addition of flux (quick lime). The oxidation of carbon generates heat which melts the scrap, and raises the liquid temperature to about 2,800°F. The CO and CO_2 produced are emitted from the vessel with a significant concentration of particulate matter which must be removed to meet the MACT particulate emission limits. The blowing process does not generate NO_X due to the complete reaction of oxygen (O_2) with the carbon in the hot metal without nitrogen (N_2) gas in the vessel (the lack of nitrogen gas (air) in the vessel prevents any possibility of forming NO_X within the molten metal – the only gases present include the O_2 being injected and CO and CO_2 being emitted, as all O_2 is consumed). At the vessel exit the gases are typically about 3,200˚F.

The BOF blowing process occurs in batch cycles with charging, blowing, and tapping events. The total cycle can be one hour with the oxygen blowing period lasting approximately 20 minutes. Off-gas temperatures entering the capture hood can be between 350 °F during charging and 3,200 °F during the peak blow of the heat cycle. U. S. Steel operates with the open-hood designs which includes full combustion of off-gases.

The full combustion operation captures the off-gases in an open hood. Ambient air is introduced between the vessel mouth and hood. The amount of air introduced is controlled by the system draft to prevent fugitive emissions and assure combustion of CO and hydrogen (H_2) emitted from the vessel. As a result of the off-gas combustion, the gas temperature increases to about 3,800 °F and NO_X can be formed as thermal NO_X. The gases are cooled by convection/radiation in the specially designed water- cooled hood and direct water spray evaporation. Gases are cooled to about 450-550° F and introduced to a cold side electrostatic precipitator (ESP) or wet scrubber for particulate removal. The particulate emitted from the furnaces is abrasive consisting of oxide forms of iron and other metals. The gas temperature and moisture content are critical for proper ESP operation. U. S. Steel operates four BOF vessels with two ESP control systems. There are 10 BOF vessels operated with five venturi scrubbers for particulate removal.

NO_X formation over the blow cycle is variable in the primary hood due to the constantly changing off-gas temperature profile and oxygen content of the gases due to hood draft requirements needed for compliance with NESHAP Part 63 Subpart FFFFF. In addition, no two heats are identical due to metal chemistry (percent carbon in hot metal (HM), silica content, etc.). The presence of carbon monoxide inhibits NO_X formation and the carbon burn rate (lb/min) during the blow period changes the CO/CO_2 percentage of the gases.

1.2.2.2 Potential for NO_X Reduction

The application of NO_X control technology before particulate removal is not feasible for these process units due to the cyclic nature of the process and presence of metallic particulate matter in the gas stream that will poison SNCR or SCR media.

In addition, the temperature in the primary hood is variable over the blow period and the required gas temperature/residence time for SNCR function cannot be achieved. Further, the required molar ratio for ammonia introduction for the NO_X ammonia reaction would be extremely difficult to meet (and potentially impossible) due to the rapidly varying NO_X formation.[10] There is no place to install an SNCR. There are no SNCR in operation across the industry. EPA hasn't provided any demonstration that SNCRs are technically feasible.

For SCR application similar conditions apply. Overall, the gases are too hot and with widely and rapidly variable temperatures, which negates the ability to use tempering air or water injection to meet the required SCR temperature (and additionally such injection may result in inappropriate conditions for proper ESP operation). Additionally, the metallic particulate will rapidly deteriorate the catalyst and poison the noble metals if used upstream of the particulate control device. Thus, an SCR pre-gas conditioning and cooling is not feasible for BOFs.

SCR could be theoretically applied after the particulate removal in the ESP or scrubber, but the BOF exhaust temperatures are only approximately 90 to 130 degrees; therefore, gases would require substantial reheating to the required SCR reaction temperature between heats and during the heat cycle requiring increased natural gas combustion, which would generate additional NO_X and Greenhouse Gases (GHGs). Further, to prevent rapid thermal degrading of the SCR catalyst, the catalyst bed would be required to be held at the operating temperature between heats, producing even more additional NO_X and GHGs. For BOFs, there are no SCRs in operation across the industry. EPA hasn't provided any demonstration that SCRs are technically feasible.

U. S. Steel evaluated RACT for BOF at Edgar Thomson in a report by AMEC Environmental and Infrastructure dated April 1, 2014. The analysis at this site is representative of BOF in the U. S. Steel fleet.

The 2014 RACT analysis found the following:

- Low NO_X burners are not technically feasible as no burners are present
- Flue gas recirculation is not technically feasible as the furnace does not operate on an air/fuel ratio basis, but instead based on high pressure oxygen lancing
- SNCR is potentially technically feasible with heating of exhaust gas, but would cost $1,143,618/ton (2014$)
- SCR is potentially technically feasible with heating of exhaust gas, but would cost $222,562/ton (2014$)
- Due to the large volume of airflow (~250,000 acfm at ~125 °F), the NO_X concentration would be extremely low and likely below the lower range concentrations to be treated by SCR

[10] One cannot monitor the pre-SNCR NO_X levels and the only available control input is the downstream NO_X levels, which cannot achieve the fine time resolution required to match the molar limit (an analogy would be driving a car through curves via using only the rearview mirror).

1.2.2.3 EPA's Proposed Limits are Not Feasible

U. S. Steel is not aware of any technically feasible NO_X control methods applicable to BOF vessels. In the non-EGU TSD, EPA incorrectly states that there is a BOF NOx emission limitation of 0.1 lb/MMBtu contained in the Ohio NO_X RACT rules. The Ohio NO_X RACT limit described in Rule 3745-110-03(N) applies to No. 1 and No. 2 BOF ladle preheaters, not the BOF.

EPA does not cite a basis for the 0.14 lb/ton reference value and cannot use an un-cited value as the basis for an emission limit. Instead, EPA only generically refers in the non-EGU TSD to

> *performance testing data from basic oxygen furnaces without NOx reduction controls at integrated iron and steel mills in the United States*

Because EPA does not cite a basis for the 0.14 lb/ton emissions level, it is not possible to review the validity of that value, nor the operating conditions under which that value was obtained. Without such documentation, EPA cannot use the 0.14 lb/ton value as the basis for an emissions limit. EPA states that there is a potential 25-50% reduction based on SCR/SNCR at the BOF, and then arbitrarily uses the upper 50% to reduce the undocumented 0.14 lb/ton value to the proposed limit of 0.07 lb/ton.

1.2.3 Electric Arc Furnaces

See the Black & Veatch Report and the discussion in U.S. Steel's comment letter for a discussion of the feasibility of control technology for electric arc furnaces.

1.2.4 Ladle/Tundish Preheaters

1.2.4.1 Description

Ladle and tundish preheaters are employed in the steel shop to dry out the ladle and tundish refractory prior to use in the steel making process after ladle repairs and to preheat the ladles and tundishes so as not to "shock" the ladle or tundish prior to hot metal or liquid steel being added. Drying out the ladles prior to use is done to prevent steam release during metal addition, which is a serious safety concern for the industry. Preheaters are also used to cure refractory after repair. Note that tundishes are only at caster facilities and are not part of a BOF Shop.

In both applications, an open gas flame is introduced into the ladle/tundish to increase the refractory temperature. The equipment is typically an air/fuel burner in a vertical (down-fire) position or horizontal position depending on the heater manufacturer. The heat input of the burner is small with multiple ladle/tundish positions. The emissions are categorized as fugitive emissions as there is no stack or control point associated with these processes.

The gas burners are very small with heat inputs of typically 5-15 MMBtu/hr. When vertically fired a cover is placed over the ladle through which the burner fires into the ladle space to keep the heat within the ladle. Combustion gases are vented through the gap under the cover via natural draft.

1.2.4.2 Potential for NOx Reduction

Gas burners can be retrofitted to a low NO_X design and some manufacturers offer low NO_X burner packages; however, emissions from these processes are low and do not meet the 100 tons per year applicability threshold either individually or combined site wide unless aggregated with the BOF Shop NOx emissions as in EPA's proposal. Therefore, the NO_X emissions reductions from ladle preheaters would also be minimal.

The use of selective non-catalytic reduction (SNCR) would be technically infeasible due to no stack or existing emissions collection systems. Also SNCR would be technically infeasible without preheating since the gas exhaust temperatures are too low for proper operation.

Practically speaking, SCR is not technically feasible on these units. SCR would require a movable hood emissions collection system, a stack, and reaction chamber, as the exhaust is not currently contained after leaving the ladle/tundish.

SCR would require significant gas reheat of a large air stream downstream to be potentially viable. Based on the above flow rates, the cost effectiveness of SCR would be at best $62,036/ton (2021$) as calculated by Trinity for a 9 MMBtu/hr unit assuming that a sufficiently tight hood could be constructed to only result in 10x the stoichiometric air flow rate, and not counting any costs for designing and constructing a hood.

1.2.4.3 EPA's Proposed Emission Limit is Not Feasible

The base case 0.1 lb/MMBtu limit is from a 2021 BACT analysis, and is the lowest possible emission rate that could be identified as RACT**.** SCR is questionably technically feasible and not cost effective. EPA's assumption of a 40% reduction using add on-control technologies is not supported by any technical analysis for a ladle preheater – there is no technical analysis in the docket or in references used as the basis for CoST and MCM for ladle preheaters. EPA has erroneously found that cost-effective emission reductions are available at a ladle preheaters by mis-using the EPA CoST model. See discussion on blast furnace stove references.

1.2.5 Reheat Furnaces

1.2.5.1 Description

Reheat furnaces are large furnaces used to raise the temperature of steel slabs through direct firing of natural gas and/or coke oven gas to process steel stabs to a temperature suitable for hot working and shaping. They are designed to accommodate the steel slabs being processed at a suitable design rate, heat it uniformly, and hold it at a desired temperature for a specified length of time.

1.2.5.2 Potential for NO_X Reduction

U. S. Steel evaluated RACT for a reheat furnace at the Irvin Plant in a report by AMEC Environmental and Infrastructure dated April 1, 2014. The analysis at this site is representative of reheat furnaces in the U. S. Steel fleet.

The 2014 RACT analysis found the following:

- SCR
  - Technically infeasible due to the failed application at a similar facility (inconsistent reductions, frequent SCR system degradation, high ammonia slip)
  - Economically infeasible even if technical challenges could be overcome at $18,764/ton (2014$)
- SNCR
  - Technically infeasible
  - Economically infeasible even if technical challenges could be overcome at $145,702/ton (2014$)

U. S. Steel additionally evaluated reheat furnaces for BART in a September 25, 2020 analysis for Gary Works by Barr. That analysis found that the cost of adding low NO_X burners would be $14,100/ton, which is not cost effective. Because of the thermodynamics of heat transfer to the steel in a reheat furnace, a lower flame temperature with low NO_X burners is expected to have negative energy usage impacts, though that impact was not quantified in the BART analysis.

1.2.5.3 EPA's Proposed Emission Limit is Not Feasible

The base case 0.073 lb/MMBtu limit is from a 2019 BACT analysis, and is the lowest possible emission rate that could be identified as RACT. SCR is questionably technically feasible and not cost effective. EPA's assumption of a 40% reduction using add on-control technologies is not supported by any technical analysis for a reheat furnace cited in the CoST modeling. The only citation for a reheat furnace in the CoST references for the proposed rule is to the addition of a low NO_X burner, based on CoST references #283, #289, and #308.

- #283 is the EPA Control Cost Manual that only instructs how to perform economic calculations
- #289 is an analysis performed as part of the NO_X SIP Call that first attempted to assess non-EGU impacts, but did not perform any analyses specific to steel units
- #304 is an EPA document about process heaters overall, focusing on chemical and petroleum refining, with no analysis of steel process heaters

EPA also erroneously found that cost-effective emission reductions are available at a reheat furnace by mis-using the EPA CoST model. The only underlying studies that attempted to calculate steel costs for SCR on a reheat furnace is the 2005 MRPO study, which lumped reheat and annealing furnaces together under a single analysis. The 2005 MRPO study values (in 2005$) for SCR range from $7,566-$13,762/ton for reheat furnaces, with numerous caveats about the generic assumptions and how site-specific variations could result in substantial cost or feasibility differences. When adjusted to 2016$ consistent with the proposed rule via a consumer price index ratio of 1.2, the 2005 MRPO cost range is from $9,079-$16,514/ton. Even without considering the various site-specific caveats in the 2005 MRPO document, and without adjusting the $/ton to reflect ozone-season only operation (with all the capital costs but only 5/12 of a year of operating time and emissions reductions), the absolute minimum cost from the 2005 MRPO report is well beyond the listed maximum cost-effectiveness threshold of $7,500 ton in the proposed rule.

In fact, the upper end of the 2005 MRPO range is very consistent with the SCR cost estimate in the 2014 Irvin RACT study ($16,514/ton vs $18,764/ton), and each is far beyond the maximum cost-effectiveness threshold in the proposed rule.

1.2.6 Annealing Furnace

1.2.6.1 Description

There are two types of annealing furnaces: batch and continuous.

Batch annealing is done in a box-type furnace that consists of a stationary base, several stools on which coils of steel are stacked, individual cylindrical covers for each coil stack (to provide for the protective atmosphere), and the furnace, which is lowered by crane over the base with its load, stools, and cylindrical covers. Subsequently, the charge is heated slowly but uniformly to a specified temperature, soaked for a period of time, and then allowed to cool. After a period of cooling, the furnace is removed to begin a cycle on another base. However, the inner covers are left in place to preserve the protective atmosphere. After the charge has cooled to about 300 °F, the charge can be exposed to air without oxidizing. In this cycle, the cooling period takes at least as long as heating and soaking combined.

Continuous annealing is done in large furnaces in which the steel coil is threaded vertically around rollers located at the top and bottom of the furnace. Thus, the residence time of the steel in the furnace is dramatically increased as it passes continuously through the furnace. A typical, continuous annealing furnace will have several zones including a gas-fired heating zone, a heated holding zone, a heated slow cooling zone, and a fast cooling zone. Steel coil will thread through these zones at a rate of about 1,500 ft/min. Threading back and forth, the steel will make multiple passes through the heating zone in about 20 seconds. Subsequently, it will be cooled to about 1000 °F in the slow cooling zone and then to 240 °F in the fast cooling zone. The entire process takes about 2 minutes and is carried out in an atmosphere of nitrogen (95 percent) and hydrogen (5 percent).

1.2.6.2 Potential for NO_X Reduction

Low NO_X burners are potentially feasible on both continuous and batch annealing furnaces, but the emissions reduction potential and the impacts to operations are unclear.

SCR is technically infeasible on a batch furnace due to the substantial temperature fluctuations in the exhaust gases.

SCR is technically feasible on an annealing furnace, but not cost effective. Most annealing furnaces with SCR have been designed to use SCR originally. Very few annealing furnaces have been retrofitted with SCR, and managing temperatures in the proper range with a retrofit unit is difficult and can require combinations of air tempering, water quenching, and natural gas preheating, depending on several factors including the thickness and width of the steel strip passing through the furnace and also dependent on stage of operations.

Trinity completed a control cost effectiveness analysis on the Irvin open coil annealing furnace, which showed that the SCR cost effectiveness would be at best $28,523 (2021$).

1.2.6.3 EPA's Proposed Emission Limit is Not Feasible

The base case 0.0915 lb/MMBtu limit is from a 2021 BACT analysis, and is the lowest possible emission rate that could be identified as RACT even-though this is BACT, not RACT.

SCR is not technically feasible on a batch annealing furnace, and on a continuous annealing furnace the annual cost effectiveness is at best $28,523/ton.

EPA has erroneously found that cost-effective emission reductions are available at an annealing furnace by mis-using the EPA CoST model. The only underlying studies that attempted to calculate steel costs for SCR on an annealing furnace is the 1994 ACT study and the 2005 MRPO study.

In the 1994 ACT study, EPA noted that there may be problems in installing SCR at existing furnaces, but for new installations estimated annual cost effectiveness up to $11,000/ton for SCR (1994$), and up to $5,000/ton for LNB/SCR (1994$), which would equate in 2022$ to approximately, $22,000/ton and $10,000/ton.

The 2005 MRPO study values (in 2005$) for SCR range from $7,566-$13,762/ton for annealing furnaces, with numerous caveats about the generic assumptions and how site-specific variations could result in substantial cost or feasibility differences. When adjusted to 2016$ consistent with the proposed rule via a consumer price index ratio of 1.2, the 2005 MRPO cost range is from $9,079-$16,514/ton. Even without considering the various site-specific caveats in the 2005 MRPO document, and without adjusting the $/ton to reflect ozone-season only operation (with all the capital costs but only 5/12 of a year of operating time and emissions reductions), the absolute minimum cost from the 2005 MRPO report is well beyond the listed maximum cost-effectiveness threshold of $7,500 ton in the proposed rule.

Regardless of the variations between these estimates, all of the estimates are substantially above the maximum cost effectiveness threshold in the proposed rule of $7,500/ton.

1.2.7 Vacuum Degasser

1.2.7.1 Description

Vacuum degassers (VDGs) are used in the steel industry to remove undesirable gases from molten steel prior to casting to produce the desired properties of the finished steel products. Specific gases to be removed can include hydrogen (H_2), oxygen (O_2), and nitrogen (N_2) dissolved in the liquid metal. They are also used to reduce the carbon content of the steel prior to casting to produce an ultra-low carbon product.

The gases are removed by reducing the pressure above the liquid metal surface to a low value typically 0.5 – 1.0 mmHg (torr). This is accomplished by placing the metal ladle in a degas tank and withdrawing air from the tank using a vacuum pump (liquid ring pump), mechanical vacuum pump, or steam ejectors. The process is typically a batch process lasting about 20 minutes in duration depending on heat size. A hard vacuum is held for about 5 minutes during which argon is injected through the ladle bottom. Stirring the metal with argon allows the dissolved gases to be released at the surface of the metal. The vacuum is then released to close to atmospheric pressure and alloy additions added by chute or on wire feeder. During this process, the metal temperature decreases and reheating can be required in a ladle metallurgical furnace (LMF) before casting.

Gas volume exhausted from the degas tank vary over the degas cycle (e.g., 250 ACFM to 3,000 ACFM) depending on specific product specifications required and degasser equipment design.

Particulate matter (PM) generated by alloy additions are typically removed by a fabric filter or cyclone before entering the vacuum pumps or steam ejectors. Steam ejectors are the most common type of degas vacuum pump used.

During degassing, dissolved oxygen in the liquid metal reacts with carbon and forms CO. If the process is to be operated to prevent carbon reaction, additions are made to the metal to consume oxygen to prevent release of dissolved oxygen to prevent CO formation.

A flare is used to combust the CO. In these systems, air is introduced with natural gas or clean desulfurized coke oven gas to supplement ignition of the flare. The higher heating value (HHV) of the process gases must be higher than 250-300 BTU/SCF to support the operation of the flare.

NO_X is not expected to be formed in the degas tank due to the gas conditions (low oxygen) and non-contact of tank gases with the metal. NO_X however can be formed in the flare flame. NO_X is not directly measured but can be estimated using emission factors.

1.2.7.2 Potential for NO_X Reduction

The application of NO_X control technology is not necessary due to low NO_X emissions nor feasible for the vacuum degasser source category due to the cyclic nature of the process and variable gas flow conditions (i.e., gas volume, temperature, and low NO_X concentrations in process gases).

- NO_X is not generated in the process and NO_X control cannot be applied.
- NO_X is generated by the flare when CO abatement is required and is a function of adiabatic flame temperature which is related to excess air, fuel usage, and flare design.
- NO_X emissions are typically estimated using emission factors derived from petrochemical operations and not directly measured.

1.2.7.3 EPA's Proposed Emission Limit Is Not Feasible

The base case 0.05 lb/MMBtu limit is from two permits (neither of which are included in the docket) and believed to be BACT analyses; BACT analyses represent the lowest possible emission rate that could be identified as RACT.

SCR is not technically feasible due to the NO_X formation occurring at a flare, which is not contained.

EPA's assumption of a 40% reduction using add on-control technologies is not supported by any technical analysis for a vacuum degasser – there is no technical analysis in the docket or in references used as the basis for CoST and MCM for vacuum degassers. In addition, EPA has erroneously found that cost-effective emission reductions are available at vacuum degassers by mis-using the EPA CoST model. See the discussion on blast furnace stove references.

1.2.8 Ladle Metallurgy Furnace

1.2.8.1 Description

Ladle metallurgical furnaces (LMF) are used in the steel industry to increase the liquid metal temperature for casting and to produce steel grades by adding alloys. After production in an electric arc furnace (EAF) or basic oxygen furnace (BOF), the ladle is covered by a water-cooled hood, and three-phase electrodes are inserted through the hood into the liquid. Electric energy is applied to achieve the required metal temperature. Alloys are injected through chutes or through wire feeders to adjust the metal chemistry for the product being produced.

Emissions from the heating and chemical reactions are vented through the area surrounding the electrodes and captured by a hood. The volume of air withdrawn for fume capture is much higher than the volume evolved from the vessel and therefore the gas temperature is low in the exhaust gas. The process is batch typically lasting 20 to 40 minutes. Generation of NO_X emissions is very low since there is no combustion source other than consumption of the electrodes by oxidation with oxygen in capture air.

1.2.8.2 Potential for NO_X Reduction

The gas temperatures and low NO_X concentrations are not consistent with application of selective catalytic reduction (SCR). The gas would require reheating using direct combustion of natural gas for SCR to be feasible.

As noted before, there is no fuel combustion taking place at the LMF, therefore there is no use for low NOx burners.

Trinity completed a control cost effectiveness analysis on the Gary Works LMF, which showed that the SCR cost effectiveness would be at best $1,733,478/ton (2021$). The natural gas combustion required for reheating the exhaust gas would result in an additional 23 tpy of NO_X which is more than the total NO_X

emissions from the LMF, as well as 27,612 tpy of additional CO_2. Additionally, the concentration of NO_X in the gas stream would be very low such that it may be below the minimum level for an SCR to achieve reductions.

1.2.8.3 EPA's Emission Limit is Not Feasible

Low NO_X burners are not technically feasible. EPA's reference to low NO_X burners in the non-EGU TSD represents a misunderstanding of LMF process operations by EPA. In addition, SCR is not cost effective.

EPA's assumption of a 40% reduction using add on-control technologies is not supported by any technical analysis for an LMF – there is no technical analysis in the docket or in references used as the basis for CoST and MCM for LMF. EPA has also erroneously found that cost-effective emission reductions are available at LMF by mis-using the EPA CoST model. See the discussion on blast furnace stove references.

In addition, EPA does not cite a basis for the 0.2 lb/ton reference value and cannot use an un-cited value as the basis for an emission limit. Instead, EPA only generically refers in the non-EGU TSD to

> *EPA considered a range of baseline emission data and current permit limits from 0.20 lb/ton to 0.35 lb/ton.*

Because EPA does not cite a basis for the 0.2 lb/ton emissions level, it is not possible to review the validity of that value, nor the operating conditions under which that value was obtained. Without such documentation, EPA cannot use the 0.2 lb/ton value as the basis for an emissions limit.

1.2.9 Coke Ovens

1.2.9.1 Description

The U. S. Steel Clairton Coke ovens are used to produce metallurgical coke from bituminous coal by indirect heating to remove volatile fractions of the coal. The coal is charged to ovens and heated for 18 to 24, hours, or more depending on coke demand, during which the off-gases are vented to a collection main and transported to a state of the art gas cleaning system, after which particulate matter (PM), ammonia, sulfur, and heavy organics are removed producing a "clean" coke oven gas (COG). The cleaned COG is primarily methane with other hydrocarbons and has a heat value of approximately 500 BTU/SCF.

The coke oven designs employed by U.S. Steel are the byproduct recovery type coke ovens. The byproduct recovery process removes ammonia, light oils, benzene, tars, and H2S limits the potential SO_2 formation during COG combustion and removes nitrogen bearing organics which would increase NO_X formation as fuel NO_X. One distinct difference between by-product recovery coke ovens and non-recovery coke oven is the COG at non-recovery coke ovens is processed to remove particulate but hydrocarbons, H_2S and nitrogen bearing components are not removed.

In a non-byproduct recovery coke oven, combustion of the COG can generate significant concentrations of SO_2 and fuel NO_X; removal of the byproducts in a byproduct recovery coke oven as at U. S. Steel results in far lower SO_2 and fuel NO_X from COG combustion.

After coking the coke is pushed into a hot car and transferred to a quench tower where direct contact with water reduces the coke temperature to prevent combustion with ambient air. The exposure of the hot coke during pushing generates PM emissions which are captured and vented to PM control systems consisting of a fabric filter baghouse. The gases are cooled using dilution air before entering the fabric filter. Since the coke oven heating is a batch process, lasting approximately 2 minutes per push and on average 6-8 pushes an hour, the volume and temperature of the push gases are variable.

Pushing emission controls can include Minister Stein type (i.e., moving hoods), fixed hoods, scrubber cars, or sheds. U.S. Steel operates 10 coke batteries with movable hoods and one shed. Volume of capture gases and gas temperatures are specific to each battery and dependent on oven size.

Minimal fugitive NO_X emissions are generated by combustion of coal particles during coal charging. Coal is charged into the ovens through four charging ports per oven. A Larry Car is used to transport coal from the coal hoppers to each oven. When the Larry Car charges an oven, the lids are removed from the charging ports and drop legs are lowered from the Larry Car to the charging port, covering the charging port. The coal is then systematically fed into an empty oven. This process takes approximately 5 minutes. Any emissions from the charging process are fugitive emissions. NO_X emissions from the process are minimal. There are no gas collection systems suitable for any NO_X controls.

1.2.9.2 Potential for NO_X Reduction

Theoretically SCR could be applied to the pushing control gases after the fabric filter, but the gases would require reheating to the activation temperature using natural gas combustion at significant cost. In addition, the NO_X emissions rate for pushing is expected to be low, decreasing control effectiveness.

Trinity calculated cost effectiveness for potential application of SCR at the Clairton C Battery coke pushing, after the baghouse. The minimum annual cost effectiveness would be $3,121,677/ton (2021$), with 72 tons of NO_X formed from combustion of natural gas to reheat the exhaust gas, as well as approximately 87,000 tpy of added CO_2.

U. S. Steel is not aware of SNCR or SCR being applied to coke oven pushing or charging emissions for coke batteries.

1.2.9.3 EPA's Proposed Emissions Limits are Not Feasible

There are no potential NO_X controls for charging. SCR is a potential NO_X control for pushing, but is not cost effective. EPA's assumption of a 50% or 25% reduction using add on-control technologies is not supported by any technical analysis for coke charging or pushing – there is no technical analysis in the docket or in references used as the basis for CoST and MCM for coke charging or pushing. See the discussion on blast furnace stove references. In addition, EPA has erroneously found that cost-effective emission reductions are available at coke oven charging and pushing by mis-using the EPA CoST model. See the discussion on blast furnace stove references.

Trinity was unable to locate a 0.3 lb/ton coke charging emission factor in AP-42, and EPA does not cite a specific reference. Because EPA's basis for the 0.3 lb/ton emissions level cannot be identified, it is not possible to review the validity of that value, nor the operating conditions under which that value was obtained. Without such documentation, EPA cannot use the 0.3 lb/ton value as the basis for an emissions limit. In addition, EPA must recognize that there are substantial differences between by-products coke oven batteries and non-recovery batteries operations.

Finally, EPA's basis for the 0.02 lb/ton factor is a recent BACT limit, and is the lowest possible emissions rate that can be identified as RACT even though this is a BACT limit and not RACT.

1.2.10 Boilers—Coal, blast furnace gas, coke oven gas

1.2.10.1 Description

Boilers operated at integrated iron and steel facilities and coke oven facilities are multi-fuel fired. Due to the age of the facilities the boilers are from different manufacturers and design (fuels used, heat release rate, and burner configuration, etc.). For these reasons, the expected NOx emission rate will vary from unit to unit burning the same fuel or fuel mixture.

In general, these boilers fire a primary fuel such as BFG or COG gas depending on boiler location, availability of fuel and quantity with natural gas as a flame stability fuel to maintain positive ignition. The boilers due to plant operation are defined as swing load with variable steam demand and therefore variable fuel firing input. Excess air is variable for each fuel type to complete combustion and therefore the flue gas volume will not be constant. The F-factor (which relates heat input to exhaust volume) for each of the fuels is significantly different depending on gas composition. BFG contains a high concentration of inert gases (CO2, N2) and a low HHV (less than 1/10th of NG) which requires a higher combustion air volume, and BFG burns with a low adiabatic flame temperature.

1.2.10.2 Potential for NO_X Reduction

Boilers were previously analyzed for NO_X reductions in multiple studies for U. S. Steel.

- RACT
  - Edgar Thompson (BFG and COG-fired) – AMEC Environmental and Infrastructure, April 1, 2014
  - Irvin (COG-fired) – AMEC Environmental and Infrastructure, April 1, 2014
- BART
  - Clairton – Trinity, March 31, 2022

For the boilers, SCR and SNCR were determined to be technically feasible, but not cost-effective. In the 2022 BART, SCR annual cost effectiveness was at minimum $20,873/ton on Boiler 2, and more expensive on others. The Irvin RACT had similar values, with SCR at ranges of $21,562-$21,778/ton (2014$). Edgar Thompson RACT was somewhat less expensive at $9,285/ton (2014$). All of these values are on an annual basis, and if evaluated for ozone season only, would be appreciably higher. However, even when considered on an annual basis, each of these cost effectiveness values is well above the $7,500/ton threshold EPA used in the proposed rule.

1.2.10.3 EPA' Proposed Emission Limits are Not Feasible

As noted, neither SCR nor low-NOx burners are cost effective options for achieving the emission limits proposed by EPA.

Additionally, the low 0.2 lb/MMBtu emission rate EPA proposes for BFG and COG boilers is well below the emission rates established in recent RACT determinations, which were 0.48 lb/MMBtu (No. 1) and 0.37 lb/MMBtu (No. 2) each on a 30-day rolling average.[11]

[11] Table V-A-1, RACT Installation Permit, ACHD # 0052-I020b, Clairton, April 24, 2020.

1.3 Limit applicability to individual units with PTE > 100 tpy

EPA focused the review for the rule on emission units emitting over 100 tpy.[12] However, EPA is unclear between the preamble and proposed rule regarding just which units the rule are subject to. Additionally, EPA inappropriately includes minor emission units for additional control in the BOF Shops.

In the preamble for steel, EPA states the following regarding applicable units.

> *The EPA is proposing to establish regulatory requirements for the Iron and Steel Mills and Ferroalloy Manufacturing source category that apply to emissions units that directly emit or have the potential to emit 100 tpy or more of NO_X and to facilities containing two or more such units that collectively emit or have the potential to emit 100 tpy or more of NO_X.*
> [87FR20145]

The proposed rule limits aggregation of units to compare against the 100 tpy threshold to the BOF Shop only.

> *The requirements of this section apply to each new or existing emissions unit at an iron and steel mill or ferroalloy manufacturing facility that directly emits or has the potential to emit 100 tons per year or more of NO_X, and to each BOF Shop containing two or more such units that collectively emit or have the potential to emit 100 tons per year or more of NO_X…*
> [proposed 40CFR52.43(b)]

Based on a phone conversation between Trinity and EPA, EPA's intent in the proposal is represented by the proposal language, where only units within the BOF Shop are aggregated; the EPA suggested that the conflicting language between the preamble and the proposed regulation may have been a carryover from an earlier draft, as EPA staff had been debating just which iron and steel emission units should be aggregated.[13]

EPA should instead limit the regulation only to individual emission units with PTE over 100 tpy, rather than aggregating additional units within the BOF Shop. EPA's definition of BOF Shop follows:

> *BOF Shop means the place where steel making operations occur, beginning with the transfer of molten iron (hot metal) from the torpedo car and ending just prior to casting the molten steel, including hot metal transfer, desulfurization, slag skimming, refining in a basic oxygen process furnace, and ladle metallurgy.*
> [proposed 40CFR52.43(a)]

Based on review of U. S. Steel operations, units that would be included in a BOF Shop are:

- BOF furnace
- Ladle metallurgy furnace (LMF)
- Vacuum degassers
- Ladle preheaters

---

[12] 87FR20083

[13] Phone conversation and email between Dylan Mataway-Novak (EPA OAQPS) and Russell Bailey (Trinity), May 23, 2022.

As discussed in Section 6.2 regarding individual units, the LMF, vacuum degassers, and ladle preheaters are small emission units and are operationally distinct from the BOF furnace. These three small emission unit types are often present at facilities outside of the BOF Shop also (such as at EAF facilities), and EPA lists no rationale in the proposed regulation for why these three small emission units should be aggregated with the BOF furnace in determining applicability.

EPA should limit the regulation only to individual emission units with PTE over 100 tpy.

1.4 Development of an emissions control plan requires at least 24 months rather than the 180 days as proposed

The proposed rule requires that affected facilities submit an emissions control plan ("work plan") with 180 days of the effective date of the rule.

> *If you are the owner or operator of an affected unit* [other than a taconite kiln]*, you must submit to EPA a work plan for each affected unit within 180 days of the effective date of this rule identifying how each affected unit will comply with the emissions limits set forth in Table 1 to paragraph (c) of this section. Each work plan must include identification of the control device selected and the phased construction timeframe by which you will design, install, and consistently operate the device.* [proposed 40CFR52.43(d)(A)

Here again as frequently throughout this proposed rule, EPA has modeled requirements for highly variable non-EGUs based on prior experience with EGUs. EPA has proposed a time period that may be appropriate had the required control device actually been installed on numerous facilities, and had those emission units actually demonstrated that the limits can be achieved (such as in the EGU sector). For the steel industry, neither is true, and 180 days is unrealistic and inadequate. Significant engineering assessments would be required in the event EPA moves forward with the proposed rule.

As discussed earlier, the only iron and steel emissions unit where the proposed control technology (SCR) has even been demonstrated has been on annealing furnaces, and even in that category there have been very few installations, and even fewer retrofits. For the remaining emission units, EPA has proposed emission limits based on installation of post-combustion control devices on these units, and there have been zero such installations that have occurred.

EPA should revise this condition to allow a minimum of 24 months to develop an emissions control plan.

1.5 Implementation of the proposed control technologies cannot be completed prior to the 2026 ozone season

As with the emissions control plan requirement, EPA made unrealistic time estimates for installation of control technologies in the steel sector, again significantly based on prior experience with EGUs. In the proposed rule, EPA is proposing that the steel sector units can install post-combustion emissions controls as fast as the EGU sector, which is unrealistic and would be devastating to steel production.

As EPA has noted in numerous prior EGU rules, electricity is fungible – should an individual EGU be offline, in nearly all cases other EGUs can provide sufficient electricity to the electrical grid to offset the loss from a single EGU. Iron and steel production facilities, including boilers at these facilities, are not fungible.

In most cases, should an emissions unit proposed to be regulated under this rule be offline, that entire section of the steel mill would also be offline. Very few steel plants have redundant steel shops, and in most cases when a key production unit is offline, that entire section of the plant is offline.

Assuming parts are available (which is not the current case with the supply chain), installing controls would require a minimum of 36 months IF there were other examples of that control be applied to that type of emissions unit (12 months to design, 18 month design end to installation end, 6 month commissioning), and that is per emissions unit. At a site with some redundancy, for example Gary Works, there are eight boilers potentially subject to this rule, which would lengthen the default 36 month period significantly (all eight boilers are not the same design and all eight boilers cannot be shut down at the same time for installation). And the timing for the installation of this equipment must be viewed against the realities of the worldwide supply chain issues, which only will be compounded by the multiple industries to be regulated in the proposed rule and the overlap in demand design services, equipment and construction services.

Because it is unrealistic and infeasible to install all of the proposed controls prior to the 2026 ozone season, EPA must revise the proposed rule to include a much longer timeframe for compliance. Additionally, because EPA's Step 2 finding that states contribute significantly is based on an analysis of 2026, and because the controls could not be installed by 2026, EPA must re-evaluate whether non-EGU emissions contribute significantly at a later time period (such as 2032 as EPA considered in development of the proposed rule).

1.6 The compliance demonstration method should be stack testing (with an implicit 3-hour average)

As written, the proposed steel rule (4 0CFR 52.43) references both a 3-hour average and a 30-day rolling average as the compliance method. Based on discussion with EPA staff, the intent of the proposed rule was to require a 3-hour averaging period using CEMS.[14]

The compliance demonstration method for the steel emission units should be stack testing, which has an implicit 3-hour average.

Installation costs of CEMs on units could cost up to $1M+ each, along with at least $50,000 in annual compliance costs related to each CEMS' maintenance and QA checks.

1.7 If CEMS are required, the averaging period should be on a 30-day rolling average

EPA has learned that for general emissions units, a 3-hour average is so short as to be unstable in demonstrating compliance. In the boiler world, EPA did issue one NSPS that uses CEMS and has a 3-hour average basis for the limit, which was NSPS Subpart D in 1974. Four years later, in 1978, EPA moved away from a 3-hour average to a 30-day rolling average basis with the new boiler NSPS Subpart D, and six years later in 1984 EPA maintained that 30-day rolling average basis with NSPS Subpart Db. Similarly, the relevant boiler NESHAP (Subparts DDDDD and UUUUU) also use a 30-day rolling average basis when a CEMS is the compliance method.

[14] Phone conversation and email between EPA OAQPS and Trinity, May 23, 2022.

For the same reasons as for boilers, a 3-hour average limit for steel emissions unit using CEMS is inappropriate. For any emissions unit where EPA requires CEMS, the averaging period should be analogous to the NSPS Subpart Da/Db approach, where 30 operating days of data are averaged for comparison to the limit.

1.8 A lb/MMBtu emissions limit is complex for a COG or BFG-fired unit using CEMS

EPA has proposed lb/MMBtu emission limits for multiple steel emission units that fire a range of fuels consisting of natural gas, COG and BFG. To calculate a lb/MMBtu limit, the F-factor of the fuel as fired must be determined (where the F-factor relates the volume of combustion exhaust to the heat input of a certain fuel, all at stoichiometric conditions).

Where an emissions unit fires COG and/or BFG as part of the fuel mix, there is not a constant F-factor. In fact, the F-factor for COG and BFG each varies significantly from the F-factor for natural gas. EPA does provide procedures for developing a custom F-factor that involves obtaining a proximate and ultimate analysis of the fuel as-fired.

It is straightforward to compare against a concentration-based NO_X limit (parts per million by volume, or ppmv), as no F-factor is needed. And it may be feasible to obtain a single F-factor during a 3-hour stack test that could be used to convert to lb/MMBtu for that test. However, it is complex to obtain customized F-factors on an hourly basis to be added to the data acquisition and handling system (DAHS) to convert ppmv to lb/MMBtu.

.

EPA 1994E

EPA's 1994 Alternative Control Techniques (ACT) document for steel assessed NO_X emission controls on two types of steel emission units included in the proposed rule: reheat furnaces and annealing furnaces, with the following types of control identified on each.

Reheat furnaces
- ► Low excess air (LEA)
- ► Low NO_X burners (LNB)
- ► Flue gas recirculation (FGR)

Annealing furnaces
- ► LNB
- ► FGR
- ► SCR

[15] From an email to Joshua Lee (Trinity) from Donnalee Jones (EPA), May 24, 2022
I think I found it. I also found a couple of other documents that might be useful also, especially the other one from 2010. I have no other documentation than what's in each document.

Reheat furnaces
EPA noted that major modifications to furnace structure and refractories in some existing reheat furnaces. EPA estimated cost effectiveness of emission these technologies at a range of costs up to approximately $1,000/ton (1994$), which is approximately $2,000/ton in 2022$ based on the difference in CPI.

Annealing furnaces
EPA noted that one unit was operational with SCR, and that three were under construction. EPA noted that there may be problems in installing SCR at existing furnaces. While EPA does not discuss continuous versus batch annealing, Trinity believes that the focus of the document was on only continuous annealing units.

EPA estimated cost effectiveness at up to approximately $2,000/ton for LNB/FGR (1994$), up to $11,000/ton for SCR (1994$), and up to $5,000/ton for LNB/SCR (1994$), which would equate in 2022$ to approximately $4,000/ton, $22,000/ton and $10,000/ton.

EPA 1998E

EPA's 1998 ozone non-EGU analysis appears to be the first time that EPA attempted to consider potential non-EGU controls with respect to development of the NO_X SIP Call.

The 1998 non-EGU document, like the EPA1994e, considered reheat and annealing furnaces. Ozone season cost effectiveness was calculated in 1990$.

Reheat furnace - $700-$900 /ton for LNB and/or FGR
Annealing furnace - $1,350-$9,070/ton for mixes of LNB, FGR and SCR

Adjusting to 2022$ would roughly double the $/ton values listed in the report, to $1,400-1,800 and to $2,700-18,140.

It is unclear how much independent research was completed for the steel industry sources. However, the following quotes from the document are germane.

> *It should be noted that although the control technologies selected for use here are generally technically feasible, certain instances are likely to exist where installation of a control is much more problematic, and hence, expensive than the existing cost data suggest. In some instances, site-specific characteristics may result in lower costs, although it is possible that the bias here is low (e.g., costs will be higher than estimated). In some cases it is also possible that the control technology is not technically feasible.*
> [Page 21]

> *Because there are more NO_X emitting source types than there is documented control technique and cost information, some assignments of control efficiency and cost information were made based on like processes being able to be controlled via like control options. This may overstate the NO_X reductions that might be achieved using today's technology.*
> [Page 61]

2005 MRPO BART

MACTEC developed $/ton NO_X estimates for model sources, while noting that site-specific factors can significantly impact the installed costs of pollution control equipment.

Of particular relevance is the lack of consideration of gas stream requirements required by an SCR system.

> *Potential site-specific costs not included but that may be necessary are additional particulate removal equipment and ductwork for a control equipment bypass. If mechanical cleaners are not present, additional gas cleaning may be needed for SCR. Some gas cleaning typically occurs at iron and steel plants. Fuel fired emission units often have bypasses on SCR systems to protect them during startup, shutdown, and malfunction conditions, which could damage the SCR catalyst. As mentioned in the technical feasibility step of the evaluation, if the temperature range is not met by the fuel fired emission unit, modifications would be required to either reduce (for units with temperatures higher than the required catalysts) or increase the boiler gas temperature. Our costs do not include estimates for reheating or providing make up air at lower temperatures to meet the required temperature levels for the SCR to operate. In the case where more heat was required to reach the catalyst temperatures, an actual design would most likely include a duct burner to re-heat the gas stream and a heat exchanger for heat recovery. In this case gas re-heat is required because the exhaust gas is too cool for SCR operating temperature. In addition to a heat exchanger, this option could incur significant costs for duct work and larger air blowers. The potential for fouling the exchanger from dust should also be evaluated. Each facility will have to determine if this option is feasible on a site-specific basis.*
> [Page 32]

The only steel-specific unit for which NO_X costs were estimated by MACTEC is furnaces. While not defined explicitly, when read in context Trinity believes these cost estimates are intended to be applicable to the same furnaces as evaluated in EPA's 1994 ACT report (EPA 1994e).

Costs for furnaces were estimated as follows (presumed 2005$/ton). The range shown is MACTEC's estimate of a low capital cost versus a high capital cost.

Furnaces
- LNB: $2,813-$5,687
- LNB+FGD: $4,205-$9,186
- SCR: $7,566-$13,762
- ULNB[16]+SCR: $8,581-$13,114

When converted to 2022$, the 2005$ are multiplied by approximately 1.5.

MACTEC concluded its model plant assessment by recommending either LNB or ULNB as BART. As noted in the conclusions:

[16] Ultra low NO_X burners

> *In general we proposed ULNB or LNB for NOx control primarily because the costs for these controls are significantly lower than other methods and the marginal improvements in control efficiency are generally not as cost effective.*
> [Page 48]

EPA 2010B

EPA 2010b is the most recent steel-specific document references by MCM or CoST, and Trinity obtained both this document as well as a May 2010 document that appears to be a peer review of an earlier draft of EPA 2010b. EPA 2010b concludes its narrative with the following statement:

> *To capture NOx emissions from this industry, the most likely opportunity is to retrofit low NOx burners into gas fired equipment.*
> [EPA 2010b, Page 1]

An estimated costs page is provided on Page 2 of EPA 2010b, showing SCR costs by CMDB Control Abbreviation, on a 2006$/ton basis.

SCR - $5,970-$7,679
LNB - $2,889
LNB+SCR - $3,964

There is no accompanying analysis to show how these values were derived. However, they are very close to the lowest cost values listed in the 2005 MRPO BART analysis. Trinity believes that the $/ton values are likely derived from the 2005 MRPO BART analysis, and for unknown reasons the creator of EPA 2010b selected the lowest potential cost for each technology.

The source categories for EPA 2010b are unclear and generic consistent with definitions in CMBD and MCM. As such, it is not clear whether EPA intends the EPA 2010b to be limited to the same types of units as EPA1994e or the 2005 MRPO BART analysis.

In the accompanying May 2010 peer review, the $/ton estimates from CoST are compared to the $/ton estimates from the 2005 MRPO BART analysis and EPA 1994e (1994 ACT). The $/ton values from CoST are appreciably lower than the other two reference sources. There is no discussion of the difference between CoST and the other two references, but there is a quote between the CoST data table and the other reference tables that appears to reference the cost difference.

> *The costs for Iron and Steel are expected to be highly site-specific and variable depending on the size of the combustion or process unit. Consequently, it is uninformative to present a single cost effectiveness number unless it incorporates a scaling factor.*

Hello Dr. Donnalee Jones,

The following is the information I was talking about on the phone regarding the document I am looking for:

- EPA, 2010: "NOX CONTROL STRATEGIES IN THE IRON AND STEEL INDUSTRY (11-11-10).pdf", pdf document provided by Donnalee Jones (jones.donnalee@epamail.epa.gov) via email to Amy Vasu 11/16/10.

This is found on the EPA menu of control measures excel sheet with the key "EPA 2010b" in the references tab. The link to the sheet from online is attached below.
~~~~~~

https://www.epa.gov/sites/default/files/2016-02/menuofcontrolmeasures.xlsx

If you could please send me this document when you get the chance that would be great. Thanks,

Joshua Lee

Control Technology for NO_x Emissions from Iron and Steel Plants

- **Have we properly characterized available NO_x controls?**
  - Low NO_x Burners (LNB)
  - LNB with Flue Gas Recirculation (FGR)
  - LNB with Selective Non-Catalytic Reduction (SNCR)
  - Ultra-Low NO_x Burners (ULNB)
  - ULNB with Selective Catalytic Reduction (SCR)
  - SCR

Response: Yes, for the most part (descriptions of these technologies are included in Appendix A). These technologies are applicable to the various types of reheat, annealing, and other gas-fired furnaces used at steel plants, as well as boilers. A review of Title V permits indicates that the most common NO_x controls used are low-NOx burners (LNB). Few of the other technologies are currently applied.

*Aside from the heating furnaces and boilers, which are primarily combustion units, other sources of NO_x include coke plant underfiring stacks, sinter plants, blast furnaces, and steelmaking furnaces. (A discussion of NO_x control for electric arc furnace (EAF) steelmaking is given in Appendix A.) Based on our study of two steel mills and a coke plant in the Detroit area (*Reference 1 *below), we concluded the following:*

"The BART analysis concluded that low-NO_x burners and ultra-low NO_x burners represented BART for iron and steel sources. As shown in Table 6-2, these controls are cost-effective. Our survey of the three plants indicated that NO_x controls were not widely implemented. The EES Coke battery's underfiring system is equipped with staged heating and flue gas recirculation to reduce NO_x emissions. U.S Steel's continuous galvanizing line is equipped with selective catalytic reduction to reduce NO_x emissions. In addition, Severstal plans to install low-NO_x burners on their blast furnace stoves."

The table below from the Detroit study shows the major contributors to NO_x emissions at integrated iron and steel plants. The reheat and other furnaces are a primary contributor, along with boilers, blast furnace (BF) stoves, basic oxygen furnaces (BOFs) used to make steel, and the coke oven combustion (or underfiring) stack.

No emissions are shown in the table for sinter plants because the Detroit steel mills do not have a sinter plant. However, there are currently five sinter plants at integrated mills, and we know that sinter plants are significant NO_x emitters.

NO_x Emission Sources (Ranked) at Iron and Steel Plants in Detroit Area (Reference 1)

Source	NO_x Emissions (tpy)	Plant
Mill furnace heaters	629	US Steel
No. 2 Boilerhouse	493	US Steel
D blast furnace stove	387	US Steel
B blast furnace stove	342	US Steel
C BF stoves	337	Severstal
Combustion stack	337	EES coke plant
Reheat furnace 1	331	Severstal
Reheat furnace 2	331	Severstal
Reheat furnace 3	331	Severstal
Blast furnace flares	330	US Steel
No. 1 Boilerhouse	322	US Steel
B BF stoves	218	Severstal
BOF	191	Severstal
Coke oven gas flares	136	Coke plant
BOF ESP stack	130	US Steel

- **What are the available documents for information on NO_x controls**
  [*Note: The first three below also have cost and cost effectiveness estimates]*

  1. Branscome, M., and S. Burns. 2006. Evaluation of $PM_{2.5}$ Emissions and Controls at Two Michigan Steel Mills and a Coke Oven Battery. Prepared for the Air Quality Strategies and Standards Division, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Research Triangle Park, NC. Available at http://epa.gov/air/caaac/aqm/detroit_steel_report_final_20060207.pdf

  2. Midwest Regional Planning Organization (RPO). *Boiler Best Available Retrofit Technology (BART) Engineering Analysis.* Prepared for The Lake Michigan Air Directors Consortium (LADCO). March 30, 2005. Available at http://www.ladco.org/reports/control/bart/iron_and_steel_mills.pdf.

  3. Alternative Control Techniques Document (ACT) – NO_x Emissions from Iron and Steel Mills. EPA September 1994. Available at http://www.epa.gov/ttn/catc/dir1/iron_act.pdf.

  4. "Proper Application of Low-NOx Technology to Reheating Furnaces – Environmental and Efficiency Advantages." (April 2005). David G. Schalles and John C. Dormire, Bloom Engineering Col Inc., Pittsburgh, PA. Published in AIST's "Iron and Steel Technology."

  5. "Fuel Savings and Reduced Emissions: Experience from 80 Oxy-fuel Installations in Reheat Furnaces." (May 2005). Per Verterberg, J. von Scheele, G. Moroz. Published in AIST's "Iron and Steel Technology."

- **How do NO_x control costs differ for subparts of the industry**

We have no information on how costs differ for different subparts. However, we expect that the size of the combustion unit is a primary factor affecting cost or cost effectiveness.

- **What Iron and Steel Sector project work is underway that may inform development of NO_x cost curves**

  None at this time.

- **What is the general assessment of workload needed to develop defensible and reliable cost**

  A. Heating furnaces and boilers at Iron and Steel plants – **hours estimated: 8 hours**

  The NO_x controls used for heating furnaces and boilers at iron and steel plants should be the same as those developed for other sources and sectors. Consequently, the research done on other sectors could be applied here. We could develop information on the size distributions of these combustion units for iron and steel plants if that would help to inform the cost analysis.

B. Other NOx Sources - **hours estimated: 40 hours**

- **Degree to which sources in industry likely to have NO_x CEMs**

  We reviewed several title V permits, and a few of the largest plants have CEMS on a few of their larger units. Most do not have CEMS, so we believe CEMS are not very widespread.

- **Reasonableness of the cost effectiveness estimates as compared to EPA estimates**

CoST Analysis Results for 2012*

Iron and Steel**	30300933 steel reheat furnaces	LNB + FGR	$600/ton
	30390004 fuel fired eq: process gas	LNB + FGR	$900/ton
	30390003 fuel fired eq: natl gas	ULNB	$2,400/ton
	30300306 coke oven underfire stack	SNCR	$2,600/ton
	30300934 steel heat treating/annealing	LNB + SNCR	$2,700/ton

* Based on the 2012 EPA inventory and NOx controls less than $5,000/ton (GSG/AQPD).
** 1.5% of overall nonEGU NOx reduction estimates.

The costs for Iron and Steel are expected to be highly site-specific and variable depending on the size of the combustion or process unit. Consequently, it is uninformative to present a single cost effectiveness number unless it incorporates a scaling factor. Estimates are given below from the BART analysis (Reference 2) and from the ACT document (Reference 3).

Summary of Cost Estimates for NO_x Controls for Furnaces at Iron and Steel Plants from the BART analysis (Reference 2) in $2004

Control Technology	Removal Efficiency %	Low Cost Effectiveness ($/ton NOx removed)	High Cost Effectiveness ($/ton NOx removed)
Low-NOx burners (LNB)	40	$2,813	$5,867
Low-NOx burners plus flue gas recirculation (LNB+FGR)	50	$6,055	$9,186
	72	$4,205	$6,379
Low-NOx burners plus selective non-catalytic reduction (LNB+SNCR)	50	$6,704	$10,493
	89	$3,766	$5,895
Ultra-low NOx burners (ULNB)	75	--	$2,018
	85	--	$1,781
Ultra-low NOx burners plus selective catalytic reduction (ULNB+SCR)	85	$9,792	$13,114
	97	$8,581	$11,492
Selective catalytic reduction (SCR)	70	$9,728	$13,762
	90	$7,566	$10,704

Summary of Costs Estimates for Controls for Furnaces at Iron and Steel Plants from EPA's ACT (Reference 3) in $2008

Type of Furnace	Control Technology	Low Cost Effectiveness ($/ton)	High Cost Effectiveness ($/ton)
Reheat Furnaces	Low Excess Air	$641	$3,752
	Low NOx Burner (LNB)	$141	$625
	Low NOx Burner plus Flue Gas Recirculation (LNB+FGR)	$172	$1,079
Annealing Furnaces	Low NOx Burner (LMB)	$313	$2,032
	Low NOx Burner plus Flue Gas Recirculation (LNB+FGR)	$406	$2,501
	Selective Non-Catalytic Reduction (SNCR)	$907	$5,784
	Selective Catalytic Reduction (SCR)	$1,876	$11,255
	Low NOx Burner plus Selective Catalytic Reduction (LNB+SCR)	$2,032	$12,349
	Low NOx Burner plus Selective Non-Catalytic Reduction (LNB+SNCR)	$891	$5,315
Galvanizing Furnaces	Low NOx Burner (LNB)	$172	$1,407
	Low NOx Burner plus flue gas recirculation (LNB+FGR)	$219	$1,876

Appendix A. Summary of NO_x Controls for Electric Arc Furnaces (EAFs)

Nitrogen oxide emissions from EAF can be electric NOx, thermal NOx, or fuel NOx. The following discusses the formation of the NOx and potential controls as taken from the steel industry's "The Making, Shaping, and Treating of Steel."

Electric NOx

Electrical NOx is formed in furnace operations when nitrogen passes through the arc between electrodes. This "electrical" NOx can be reduced by reducing the amount of nitrogen available in the furnace. This can be achieved by closing up furnace gaps and by closing the slag door whenever possible. Many operations lance oxygen through the door and, as a result, a large volume of air enters the furnace. This can be reduced by providing a shield close to the door or by hanging chains close to the opening. Foamy slag practice can be beneficial since the slag foams up partially blocking the opening. Also, since foamy slag helps to bury the arc, it is more difficult for nitrogen to pass through the arc and be ionized.

Thermal NOx

Thermal NOx is generated from burner use in EAFs. Typical levels of NO_x reported are in the range of 36–90 g NO_x per ton of steel. Thermal NOx can be addressed using any of the conventional control methods. Typically, thermal NO_x is reduced by improving the burner design and providing good mixing of the pre-combustion gases. Thermal NO_x is also formed in the water-cooled duct following the combustion air gap as any combustible materials burn with the oxygen which has entered the ductwork in the combustion air. If all of the combustible material burns quickly, the gas temperature will reach a level where thermal NO_x is formed. One option which is now being investigated is to close up the combustion gap somewhat and to supply combustion air at various points in the water-cooled duct downstream of the combustion gap through injectors. Thus the combustion will be staged along the first two-thirds of the water-cooled duct and will avoid the temperatures associated with thermal NO_x generation.

Fuel NOx

As with most fuel-fired NO_x sources, there are two broad categories of NO_x reduction techniques: (1) process controls, including combustion modifications, that rely on reducing or inhibiting the formation of NO_x in the production process and (2) post-combustion (secondary) add-on controls, where flue gases are treated to remove NO_x that has already been formed.

For iron and steel plants, six different control technologies or control technology combinations were identified for NO_x emissions from fuel-fired emission units at iron and steel plants. These technologies, which provide both combustion or post-combustion controls (or a combination of both), are described below.

Flue gas recirculation (FGR) uses flue gas as an inert material to reduce flame temperatures. In a typical FGR system, flue gas is collected from the heater or stack and returned to the burner via a duct and blower. The flue gas is mixed with the combustion air and introduced into the burner. The addition of flue gas reduces the oxygen content of the combustion air, which in turn reduces flame temperatures, resulting in lower NO_x emissions.

Typical NO_x control efficiency for FGR ranges from 30 percent to 50 percent, or 50 to 72 percent when coupled with low-NO_x burners.

Low-NOx burner (LNB) technology uses advanced burner design to reduce NO_x formation through the restriction of oxygen, flame temperature, and/or residence time. LNB is a staged combustion process that is designed to split fuel combustion into two zones: primary combustion and secondary combustion.

Two general types of LNBs exist: staged fuel and staged air. Staged-fuel LNBs separate the combustion zone into two regions. In the first region, combustion takes place in the presence of a large excess of oxygen at substantially lower temperatures than a standard burner. In the second region, the remaining fuel is injected and combusted with any oxygen left over from the primary region. The remaining fuel is introduced in the second stage outside of the primary combustion zone so that the fuel and oxygen are mixed diffusively (rather than turbulently) which maximizes the reducing conditions. LNBs inhibit the formation of thermal NO_x, but have little effect on fuel NO_x. Therefore, staged-fuel LNBs are particularly well suited for coal- and natural gas-fired emissions units that are higher in thermal NO_x. The estimated NO_x control efficiency for LNBs in high-temperature applications is 25 percent. However, when coupled with FGR or selective non-catalytic reduction (SNCR), these efficiencies increase to 50 to 72 and 50 to 89 percent, respectively.

Ultra low-NO_x burners (ULNB) combine the benefits of flue gas recirculation and low-NO_x burner control technologies. Rather than a system of fans and blowers (like FGR), the burner itself is designed to recirculate hot flue gas from the flame or firebox back into the combustion zone. This leads to a reduction in the average oxygen concentration in the flame without reducing the flame temperature below that necessary for optimal combustion efficiency. Because of this reduction in temperature, ULNB would likely only be applicable to processes at iron and steel plants that are not temperature dependent, unless the reduction in flame temperature does not fall below the required threshold temperature for the process. The estimated NO_x control efficiency for ULNBs in high-temperature applications is 50 percent. Newer designs have yielded efficiencies between 75 to 85 percent. When coupled with selective catalytic reduction, efficiencies from 85 to 97 percent can be obtained.

Selective non-catalytic reduction (SNCR) is a control process that injects urea or ammonia-based chemicals into the flue gas stream to convert NO to N2 and water. Without the participation of a catalyst, the reaction requires a high temperature range to obtain activation energy. The reaction with urea is as follows:

$$2NO + CO(NH_2)_2 + 1/2\ O_2 \rightarrow 2N_2 + CO_2 + 2\ H_2O$$

The optimum operating temperature for SNCR is 1,600°F to 2,100°F. Under these temperature conditions, a significant reduction in NO_x occurs. At temperatures above 2,000°F, an alternative reaction occurs and NO_x control efficiency decreases rapidly. The normal NO_x control efficiency range for SNCR is 50 to 70 percent. To date, there are no known installations of SNCR at iron and steel plants, although SNCR potentially could be used for some operations within an iron and steel plant.

Selective catalytic reduction (SCR) is a post-combustion NOx control technology in which ammonia (NH3) is injected into the post-combustion gas stream in the presence of a catalyst. A catalyst bed containing metals in the platinum family is used to lower the activation energy required for NOx decomposition. NOx is removed through the following chemical reaction:

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$

The reaction of NH_3 and NOx is favored by the presence of excess oxygen. However, the primary variable affecting NOx reduction is temperature. Optimum NOx reduction occurs at catalyst bed temperatures of 600–750°F for conventional catalysts (vanadium or titanium based) and 470–510°F for platinum catalysts. A high temperature zeolite catalyst is also available; it can operate in the 600–1000°F temperature range.

A given catalyst typically provides optimal performance within ± 50°F of its design temperature for applications in which flue gas oxygen concentrations are greater than 1 percent. Below this optimum range, the catalyst activity is greatly reduced allowing unreacted NH_3 to slip through (ammonia slip). At temperatures above 850°F, ammonia begins to oxidize to form additional NOx. The NH_3 oxidation to NOx increases with increasing temperature. The normal NOx control efficiency range for SCR is 70 percent to 90 percent. SCR has been extensively and quite successfully used in a very cost effective manner on coal- and gas-fired utility boilers, industrial boilers, gas turbines and internal combustion diesel engines in the United States. There have been few uses of SCR in the iron and steel industry. At the time the EPA's ACT NOx document was published, Japanese iron and steel mills had been experimenting with SCR for sinter plants and coke ovens, however these efforts at that time were experimental.

As indicated above, SCR has been used with annealing furnaces. There are few other references to the use of SCR for NOx control for other emission processes at iron and steel plants. MACTEC did find one example usage of SCR for controlling sintering plant exhaust gases. Of particular interest in that example installation was the use of iron ore as the catalyst. The benefit of using iron ore as the catalyst was that unlike other types of catalyst which have a solid waste disposal component, the iron ore can be used directly as a steel making raw material, thus obviating the solid waste disposal issue. In the SCR process, typically, anhydrous ammonia usually diluted with air or steam is injected into hot flue gases, which then pass through a catalyst bed where NOx is reduced to nitrogen gas and water. As indicated above, the optimum temperature for SCR depends on the catalyst. Thus the exit gas temperatures from some of the processes at iron and steel plants may either be too high or too low, requiring either reheat (if too low) or dilution/quenching (if too high) in order to effectively use SCR. Thus careful consideration should be given on a source-specific basis depending on how raw materials are currently processed.

Burner Technology Options for NOx control include the following:

- Nonsymmetrical air-staged burner for longitudinal or side-fired zones
- Air-staged burner for roof firing
- Air-staged long flame burners for low-pressure fuels
- Ultralow-NOx regenerative burners

NO_X CONTROL STRATEGIES IN THE IRON AND STEEL INDUSTRY (11-11-10)

We reviewed the table of strategies for NOx control in the iron and steel industry and identified CMDB processes: NSNCRCMOU, NDSCRFPGCO, NDSCRUPGCO, NDSCRUNGGN, NLNBUNGGN and NLNBUPGCO, NDSCRUROGN, NDSCRBCGN, NSNCRBCGN, and NLNBFCOBF, as possibilities for use in the iron and steel industry. See attached table.

Our present focus for regulatory review in the integrated iron and steel segment is sinter plants, blast furnaces and basic oxygen process furnaces. The Alternative Control Techniques Document --NO_x Emissions from Iron and Steel Mills, September, 1994 (EPA-453/R-94-065) is 16 years old, but there has not been much new construction in the industry. At the time this study was done, EPA had no recommendations for the processes that we are currently targeting but suggested low NO_x burners and *possibly* SCR for some gas fired equipment at iron and steel plants such as annealing furnaces, preheating furnaces and boilers. (NO_x control options for boilers at iron and steel facilities are about the same as those for boilers anywhere.)

A BART (Best available retrofit technology) study was done in 2005 by MACTEC [Midwest Regional Planning Organization (RPO): Iron and Steel Mills Best Available Retrofit Technology (BART) Engineering Analysis, MACTEC, March 30, 2005. This study looked at two steel mills in the Midwest and found that no low NO_x technologies were in place at these plants. For processes on which we are focusing, the recommended retrofits technologies of ultralow NO_x burners (ULNB) for the sinter plant windbox and low NO_x burners (LNB) or ULNB for coke oven underfire. For other emission points (general gas fired equipment) they recommended retrofit technologies of LNB or ULNB for boilers, slab furnaces, annealing furnaces, hot strip mill furnaces, heat soaking, etc. They also recommended ULNB for the refining cycle (but not for charging, tapping, or slagging) of the basic oxygen furnace.

Bearing in mind that there are many different combustion processes at a steel plant, some NO_x reductions may be achieved at some points in the process. NSNCRCMOU and NSNCRBCGN are selective non-catalytic reduction processes which were considered infeasible in the BART study. NDSCRUROGN and NDSCRBCGN are unlikely because little if any residual fuel oil is combusted (it is possible but unlikely) and little if any bituminous coal is combusted (a fraction of the coke is sometimes replaces with coal, because it is cheaper, but not very much). NDSCRFPGCO, NDSCRUPGCO and NDSCRUNGGN are SCR processes which the Bart study considered feasible (for some emission points). NLNBUNGGN/NLNBUPGCO, and NLNBFCOBF are low NO_x burner processes which were considered feasible in the Bart study (for some emission points).

To capture NO_x emissions from this industry, the most likely opportunity is to retrofit low NO_x burners into gas fired equipment. Also, for boilers at steel plants as with boilers everywhere, other types of “combustion modifications” may be possible.

Control Options for Reducing Nitrogen Oxides Emissions from Point and Area Sources

Iron and Steel?	CMDB Control Abbreviation	Emission Reduction Measure Name (Note)	Source Category	Control Efficiency (%)	Cost Effectiveness (2006$/ton reduced)	References	Description/Notes/Caveats
Yes	NDSCRFPGCO	Selective Catalytic Reduction--(Bart study considered SCR feasible)	In-Process - Process Gas - Coke Oven Gas	90	$7,679	167	This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control applies to process gas fired ICI boilers with NOx emissions greater than 10 tons per year.
Yes	NDSCRUPGCO	Selective Catalytic Reduction-(About same as NDSCRFPGCO)	In-Process - Process Gas - Coke Oven Gas	90	$5,970	167	Application: This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control is applicable to operations with in-process process gas usage from Coke Oven Gas.
Yes	NDSCRUNGGN	Selective Catalytic Reduction-(Very similar to NDSCRFPGCO)	In-Process Fuel Use - Natural Gas	90	$5,970	167	This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control is applicable to operations with in-process natural gas usage and uncontrolled NOx emissions greater than 10 tons per year.
Yes	NLNBUNGGN and NLNBUPGCO	Low NOx Burner--(Bart study considered this feasible)	In-Process Fuel Use - Natural Gas or Coke Oven Process Gas	50	$3,531 for NOx<1 tpd and $2,889 for NOx>1 tpd	72, 175, 179, 186	This control is the use of low NOx burner (LNB) technology to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to operations with in-process coke oven gas usage and natural gas-fired process heaters with uncontrolled NOx emissions greater than 10 tons per year.
Yes	NLNBFCOBF	Low NOx Burner and Flue Gas Recirculation--(Bart study considered this feasible)	In-Process -Process Gas -Coke Oven/ Blast Furnace	55	$5,120 for NOx<1 tpd and $3,964 for NOx>1 tpd	72, 172, 175, 179, 186	This control is the use of low NOx burner (LNB) technology and flue gas recirculation (FGR) to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to in-process coke/blast furnaces and uncontrolled NOx emissions greater than 10 tons per year.
Maybe	NDSCRUROGN	Selective Catalytic Reduction-(Use of residual fuel oil is not usually practiced in Iron and Steel, but could be used for a boiler or process heater on site)	In-Process Fuel Use - Residual Oil	90	$5,374	167	This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control is applicable to operations with in-process residual oil usage and uncontrolled NOx emissions greater than 10 tons per year.
Maybe	NDSCRBCGN	Selective Catalytic Reduction--(Not likely in Iron and Steel except where some coke is replaced with coal due to lower cost)	In-Process Fuel Use - Bituminous Coal	90	$3,649	167	This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control applies to operations with general (in process) bituminous coal use and uncontrolled NOx emissions greater than 10 tons per year.
No	NSNCRCMOU	Selective Non-Catalytic Reduction--(Bart study considered SNCR infeasible)	By-Product Coke Manufacturing - Oven Underfiring	60	$2,632	72, 172, 175, 179, 181	This control is the reduction of NOx emission through selective non-catalytic reduction add-on controls. SNCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). This control applies to all by-product coke manufacturing operations with oven underfiring and uncontrolled NOx emissions greater than 10 tons per year.
No	NSNCRBCGN	Selective Non-Catalytic Reduction--(Bart study considered SNCR infeasible)	In-Process Fuel Use - Bituminous Coal - Gen	40	$2,022 for NOx<1 tpd and $1,509 for NOx>1 tpd	72, 172, 175, 179, 185	This control is the reduction of NOx emission through selective non-catalytic reduction add-on controls. SNCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). This control applies to operations with general (in process) bituminous coal use and uncontrolled NOx emissions greater than 10 tons per year.

Midwest Regional Planning Organization (RPO) Iron and Steel Mills Best Available Retrofit Technology (BART) Engineering Analysis

SECTION 1
OVERVIEW

INTRODUCTION

An appropriate first step in evaluating BART for a group of sources is to categorize emission units within each general source category. For this work, the source categories included (BART numeric category in parentheses):

- Portland cement plants (4),
- Iron and steel mill plants (6),
- Primary aluminum ore reduction plants (7),
- Petroleum refineries (11),
- Primary lead smelters (17),
- Chemical process plants (21), and
- Fossil-fuel boilers of more than 250 million BTUs per hour heat input (22)

In general, these types of emission units were found in several of the LADCO States. In order to effectively characterize the BART controls for these emission sources, MACTEC determined that using an initial “model” emission source for each category would be the most effective means of evaluating the types of emission units and the likely candidate BART controls for each.

For each of these emission sources, MACTEC developed “model sources” to enable the development of representative control cost estimates. The physical characteristics of the model sources are summarized in each section specific to that source category. The model sources were selected to reflect typical emission units found at each emission source type.

SECTION 2
AVAILABLE CONTROL TECHNOLOGIES

INTRODUCTION

This section describes each potentially available control technology evaluated for BART category 6, iron and steel plants. For iron and steel plants, the control technologies can be largely focused by pollutant and emission unit type within the facility. Table 2.1 shows the types of emission sources (summarized by SCC) that were found to be potentially subject to BART for iron and steel plants. From this table it can clearly be seen that the majority of emissions of SO_2 and NO_x are generally associated with fuel firing operations, in this case either boilers or process heaters. There are also emissions of SO_2 from SCC 30300699. The SCC description indicates that emissions are from unclassified open furnace activities. In this case, these emissions are from sinter heating/processing, which is also likely to be fuel based. For NO_x there are also emissions from hot metal transfer. The hot metal transfer emission unit description refers to basic oxygen furnace refining cycle processes. As a consequence, our discussion of BART for iron and steel plants will focus on fuel combustion controls for the SO_2 and NO_x sources, since this will account for controls on 100 percent of the SO_2 and over 96 percent of the NO_x. Fuel firing sources also account for 45 percent of the PM and 68 percent of the VOC emissions. For the remaining sources (which are primarily PM and VOC emitters) the BART analysis will focus only on controls for those pollutants.

For fuel firing equipment, the control devices will be very similar to those identified for boilers (BART category 22). SO_2 controls evaluated include advanced flue gas desulfurization (AFGD), wet FGD and dry FGD. NO_x, controls evaluated include low NO_x burners (LNB), flue gas recirculation (FGR), selective catalytic reduction (SCR), and selective non-catalytic reduction (SNCR). PM controls include fabric filters (both typical baghouse setups and baghouses with traveling hoods), dust cartridges (DC), and wet and dry electrostatic precipitators (ESP). In addition, for PM only sources (especially fugitive ones), best management practices need to be examined to determine if they are sufficient for BART. For this section, the technologies are grouped by the pollutant that they control for fuel fired sources (i.e., NO_x, SO_2, PM, or VOC). That is followed by a section discussing the technologies available for PM only sources.

Determining technical feasibility of a control technology for a new source (e.g., determining best available control technology for a new process heater source at an iron and steel plant) is different than determining technical feasibility for a retrofit at an existing source (e.g., determining best available retrofit technology for an existing process heater at an iron and steel plant). In this section, MACTEC determines the technical feasibility of each of at least three control technologies (if available) for fuel fired and PM only units at a typical iron and steel plant. As part of the BART screening evaluation, a literature/internet/vendor review was conducted to identify potential control equipment options for the emission units identified (see below). The controls identified represent the top three options (based on control efficiency and costs) for these units. The top controls were identified in a spreadsheet provided to LADCO in December 2004 and updated in January 2005 to address comments received on the December spreadsheet.

In the section that follows, MACTEC further evaluates the technical feasibility of each control technology as a retrofit to the existing emission units identified in task 2 of this contract (and provided in a spreadsheet to LADCO participants in October 2004). The emission units identified in that spreadsheet were selected based on three criteria: 1) emission levels for SO_2 and NO_x; 2) commonality of sources (i.e., how many similar sources occurred across the LADCO region and; 3) the potential impact of emissions from these units at Class I areas (as determined by Q/D [emissions/distance] values for several Class I areas in or near the LADCO region). In addition, cost estimates have been modified to the extent possible to reflect actual emission unit operational conditions.

Table 2.2 shows the iron and steel plant emission units identified for LADCO as meeting the three criteria listed above. These emission units were evaluated for BART.

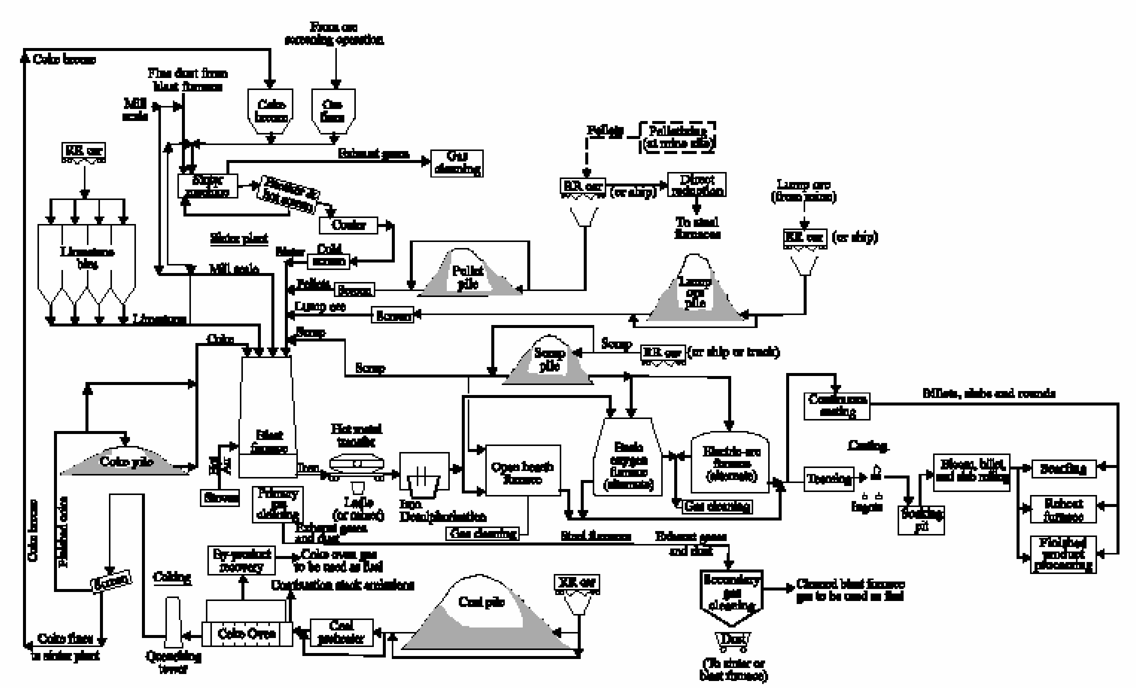
Figure 2.1 shows a process flow diagram of an iron and steel plant. The process flow diagram (taken from AP-42) shows all types of furnaces including electric arc furnaces. None of the sources in the LADCO region appear to be minimills.

FIGURE 2.1. IRON AND STEEL PLANT PROCESS FLOW DIAGRAM.



The major iron and steel plant operations shown in Figure 2-1 are: (1) coke production, (2) sinter production, (3) iron production, (4) iron preparation, (5) steel production, (6) semifinished product preparation, (7) finished product preparation, (8) heat and electricity supply, and (9) handling and transport of raw, intermediate, and waste materials. The relationships between these operations is shown in Figure 2.1.

As Tables 2.1 and 2.2 indicate, the majority of SO_2 and NO_x emissions are associated with the boilers, furnaces and other types of process heaters involved in coke production, sinter production, and iron and steel production.

Coke used for metallurgical processes is produced by destructively distilling coal in coke ovens. The coal is heated in an oxygen-free atmosphere (–coked–) to remove the majority of the volatile components. The residual material is known as coke. Metallurgical coke is used in iron and steel industry processes (primarily in blast furnaces) to reduce iron ore to iron. Over 90 percent of the total coke production in the United States is dedicated to blast furnace operations. The remaining 10 percent is foundry coke which uses a different blend of coking coals, longer coking times, and lower coking temperatures relative to those used for metallurgical coke to produce the final product. Foundry coke is used in foundry furnaces for melting metal and in the preparation of molds. Coke plants are generally collocated with iron and steel production facilities, and the demand for coke generally corresponds with their production levels. There has been a steady decline in the number of coke plants over the past several years for many reasons, including a decline in the demand for iron/steel, increased production of steel by mini-mills (electric arc furnaces that do not use coke), and the lowering of the coke:iron ratio used in the blast furnace (e. g., increased use of pulverized coal injection).

Sintering is a process that converts fine raw materials (iron ore, coke breeze, limestone, mill scale, and flue dust) into an agglomerated product, sinter, in a size that is conducive for charging into the blast furnace. The raw materials are sometimes mixed with water to provide a cohesive matrix, and then placed on a continuous, traveling grate called the sinter strand. A burner hood, at the beginning of the sinter strand ignites the coke in the mixture, after which the combustion is self supporting and it provides sufficient heat, 1300 to 1480°C (2400 to 2700°F), to cause surface melting and agglomeration of the mix. The burner hood and the combustion of the sinter mixture is the predominant source of gaseous emissions from this process. Underneath the sinter strand is a series of windboxes that draw combusted air down through the material bed into a common duct, generally leading to a gas cleaning device. At the end of the sinter strand, the fused product is discharged where it is crushed and screened. Undersize sinter is recycled to the mixing mill and back to the strand. Following the crushing and screening, the sinter product is cooled in open air or in a circular cooler with water sprays or mechanical fans. It is then crushed and screened for a final time and the appropriately sized material is sent to be charged in the blast furnace. About 2.5 tons of raw materials, including water and fuel, are required to produce 1 ton of product sinter.

Iron is produced in blast furnaces by the reduction of iron bearing materials with a hot gas in a large, refractory lined furnace. The furnace is charged through its top with iron as ore, pellets, and/or sinter; flux as limestone, dolomite, and sinter; and coke for fuel. Iron oxides, coke and fluxes react with the blast air to form molten reduced iron, carbon monoxide (CO), and slag. While the molten iron and slag are collected in a hearth at the base of the furnace, the byproduct gas is collected through offtakes located at the top of the furnace and is recovered for use as fuel. The production of 1 ton of iron requires 1.4 tons of ore or other iron bearing material; 0.5 to 0.65 tons of coke; 0.25 tons of limestone or dolomite; and 1.8 to 2.0 tons of air. Byproducts consist of 0.2 to 0.4 tons of slag, and 2.5 to 3.5 tons of blast furnace gas containing up to 100 pounds (lb) of dust.

The molten iron and slag are removed, or cast, from the furnace on a periodic basis. The casting process begins by drilling a hole, called the taphole, into the clay-filled iron notch at the base of the hearth. The molten iron then flows into runners that lead to transport ladles. Separate runners are used to direct flows of slag from the furnace to a slag pit adjacent to the casthouse, or into slag pots for transport to a remote slag pit. At the conclusion of the cast, the taphole is replugged with clay. The area around the base of the furnace, including all iron and slag runners, is enclosed by a casthouse. The byproduct gas collected at the top of the furnace contains CO and particulate. Because of its high CO content, the blast furnace gas has a low heating value, about 75 to 90 BTU/ft^3, and is used as a fuel within the steel plant. Before it can be fired however, the gas must be cleaned of particulate. Initially, the gases pass through a settling chamber or dry cyclone to remove about 60 percent of the particulate. Next, the gases undergo a 1- or 2-stage cleaning operation, typically a wet scrubber (for a single stage cleaner), which removes about 90 percent of the remaining particulate. If a 2-stage cleaner is used, the secondary cleaner is typically a high-energy wet scrubber (usually a venturi) or an electrostatic precipitator, either of which can remove up to 90 percent of the particulate that eludes the primary cleaner. Together these control devices provide a clean fuel of less than 0.02 grains per cubic foot [g/ft^3]. A portion of this gas is fired in the blast furnace stoves to preheat the blast air, and the rest is used in other plant operations.

Sulfur in the molten iron is sometimes reduced before charging into the steelmaking furnace by adding reagents. This is known as hot metal desulfurization. The reagents cause a reaction that results in floating slag which can be skimmed off. Desulfurization may be performed in the hot metal transfer (torpedo) car at a location between the blast furnace and basic oxygen furnace (BOF), or it may be done in the hot metal transfer (torpedo) ladle at a station inside the BOF shop. Typically the reagents used for the reaction are powdered calcium carbide (CaC_2) and calcium carbonate ($CaCO_3$) or salt-coated magnesium granules. Powdered reagents are injected into the metal through a lance with high-pressure nitrogen. The process duration varies with the injection rate, hot metal chemistry, and desired final sulfur content, and is in the range of 5 to 30 minutes.

Steel is typically made using basic oxygen furnaces (BOF) which employee the basic oxygen process (BOP). In the BOP, molten iron from a blast furnace and iron scrap are refined in a furnace by lancing (or injecting) high-purity oxygen. The input material is typically 70 percent molten metal and 30 percent scrap metal. The oxygen reacts with carbon and other impurities to remove them from the metal. Since the reactions are exothermic, no external heat source is required to melt the scrap and to raise the temperature of the metal to the desired range for tapping. The large quantities of CO produced by the reactions in the BOF can be controlled by combustion at the mouth of the furnace and then vented to gas cleaning devices, as with open hoods, or combustion can be suppressed at the furnace mouth, with closed hoods. BOP steelmaking is conducted in large (up to 400 ton capacity) refractory lined pear shaped furnaces. There are 2 major variations of the BOP. In conventional BOFs, oxygen is blown into the top of the furnace through a water-cooled lance. In the newer, Quelle Basic Oxygen process (Q-BOP), oxygen is injected through tuyeres located in the bottom of the furnace. A typical BOF cycle consists of the scrap charge, hot metal charge, oxygen blow (refining) period, testing for temperature and chemical composition of the steel, alloy additions and reblows (if necessary), tapping, and slagging. The full furnace cycle typically ranges from 25 to 45 minutes.

Steel can also be made using electric arc furnaces (EAF). EAFs are normally used to produce carbon and alloy steels. The input material to an EAF is typically 100 percent scrap. Cylindrical, refractory lined EAFs are equipped with carbon electrodes to be raised or lowered through the furnace roof. With electrodes retracted, the furnace roof can be rotated aside to permit the charge of scrap steel by overhead crane. Alloying agents and fluxing materials usually are added through doors on the side of the furnace. The electrodes generate heat by having electric current of opposite polarities pass through each electrode. After melting and refining periods, the slag and steel are poured from the furnace by tilting. The production of steel in an EAF is a batch process. Cycles, or "heats", range from about 1-1/2 to 5 hours to produce carbon steel and from 5 to 10 hours or more to produce alloy steel. Scrap steel is charged to begin a cycle, and alloying agents and slag materials are added for refining. Stages of each cycle normally are charging and melting operations, refining (which usually includes oxygen blowing), and tapping.

Steel may also be made using open hearth furnaces (OHF), which are shallow, refractory-lined basins in which scrap and molten iron are melted and refined into steel. The furnace is charged with scrap through doors in the furnace front. Hot metal from the blast furnace is added by pouring from a ladle through a trough positioned in the door. The mixture of scrap and hot metal can vary from all scrap to all hot metal, but typically a half-and-half mixture is most common. The heat for melting is provided by gas burners above and at the side of the furnace. Refining is accomplished by the oxidation of carbon in the metal and the formation of a limestone slag to remove impurities. Most furnaces are equipped with oxygen lances to speed up melting and refining. The steel product is tapped by opening a hole in the base of the furnace with an explosive charge. The open hearth steelmaking process with oxygen lancing normally requires from 4 to 10 hours for each heat.

Once the steel has been tapped from a furnace, the molten metal is poured (teemed) into ingots which are later heated and formed into other shapes, such as blooms, billets, or slabs. The molten steel may bypass this entire process and go directly to a continuous casting operation. Whatever the production technique, the blooms, billets, or slabs undergo a surface preparation step, scarfing, which removes surface defects before shaping or rolling. Scarfing can be performed by a machine applying jets of oxygen to the surface of hot semifinished steel, or by hand (with torches) on cold or slightly heated semifinished steel.

For fuel fired sources at iron and steel plants, control technology options identified for SO_2 include advanced flue gas desulfurization (AFGD), dry FGD, and wet FGD; control technology options for NO_x

include low NO_x burners (LNB), LNB with flue gas recirculation (FGR), LNB with selective non-catalytic reduction (SNCR), ultra-low-NO_x burners (ULNB), ULNB with selective catalytic reduction (SCR), and SCR by itself, depending upon the source type. For PM emissions, dust collectors (DC), fabric filters (FF), fabric filters with traveling hoods, wet electrostatic precipitators (WESP), and dry electrostatic precipitators (DESP) were considered. In addition for some of the PM only sources that are primarily fugitive in nature, enclosures (EC) were also identified as PM controls. Table 2.3 indicates the pollutant controls identified for each process at iron and steel plants by pollutant for the three primary controls (where available).

Similarly to our treatment of industrial boilers subject to BART, in cases where the emission unit had more than one fuel type (segment) the primary fuel was used to develop cost estimates. Where similar sources (e.g., process heaters) fired different fuels and each fuel was used as a primary fuel for at least one emission unit, MACTEC prepared separate cost estimates for each fuel type.

NO_x Emission Control Options

Integrated iron and steel mills typically produce steel by reducing iron ore to iron in a blast furnace followed by removal of excess carbon and other impurities from the iron in a basic oxygen furnace. Other processes involve pelletizing iron ore, recycling of iron-bearing materials (e.g., sintering), coke-making, and steel finishing processes such as shaping, annealing, and galvanizing. All of these are high temperature processes which usually involve the combustion of fossil fuels, and all are potential sources of NO_x emissions. The following iron and steel processes are all specifically capable of generating NO_x:

- Coke oven underfiring - a high-temperature process with NO_x emissions from coke oven gas (COG), natural gas (NG), and/or blast furnace gas (BFG).
- Sinter plant - iron ore fines, coke fines, other iron-bearing materials, and (often) flux are well-mixed and spread uniformly on a traveling grate and ignited, typically with NG.
- Blast furnace – while the blast furnace itself is a closed system with no atmospheric emissions, each blast furnace typically has three or four associated stoves that preheat the air blast supplied to the blast furnace. Because these stoves are heated primarily with BFG, NO_x emissions from the stoves generally have low concentrations.
- Charging – during charging, combustible off-gases are generated. Generally these are collected by hoods and then burned (frequently in flares). During the combustion of the off-gas, thermal NO_x is generated.
- Electric arc furnace steelmaking - the use of electricity for steel melting transfers the generation of NO_x from the iron and steel mill to a utility generating plant, however, oxygen and NG are sometimes used to preheat the charge. Thus EAF's are potential NO_x emission sources.
- Molten steel processing - slabs, billets, and blooms may be reheated to suitable working temperatures in reheat furnaces prior to being passed through mills for further shaping. Ingots are typically reheated in soaking pits prior to subsequent processing. Reheat furnaces and soaking pits are high-temperature, fossil fuel (typically natural gas) burning furnaces and are sources of NO_x emissions.
- Finishing processes - annealing and galvanizing also involve reheating steel products to suitable temperatures for processing. Consequently, these finishing processes are also sources of NO_x emissions.

There are three fundamentally different mechanisms of NO_x formation. These mechanisms yield (1) thermal NO_x, (2) fuel NO_x, and (3) prompt NO_x. The thermal NO_x mechanism arises from the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules in combustion air. The fuel NO_x mechanism arises from the evolution and reaction of fuel-bound nitrogen compounds with oxygen. The prompt NO_x mechanism involves the intermediate formation of hydrogen cyanide (HCN), followed by the oxidation of HCN to NO_x. Natural gas and most distillate oils have no chemically bound fuel nitrogen and essentially all NO_x formed from the combustion of these fuels is thermal NO_x. Residual oils and coals all have fuel-bound nitrogen and, when these are combusted, NO_x is formed by all three mechanisms. Iron and steel mill processes tend to use gaseous fuels, i.e., NG, COG, BFG, and oxygen, and the NO_x generation tends to be thermal NO_x. Exceptions include sintering where coke fines are burned as a fuel and coke ovens where coal is destructively distilled in the absence of air. Emissions from sintering and fugitive emissions from coke ovens may be sources of fuel NO_x emissions. Prompt NO_x formation is not a major factor. It forms only in fuel-rich flames, which are inherently low NO_x emitters. Thermal NO_x formation is the predominant mechanism of NO_x generation at iron and steel mills.

Very little NO_x emissions data are available in the literature relevant to iron and steel processes. In fact the most current chapter of AP-42 concerning iron and steel processes shows no emission factors for NO_x (or SO_2). The Alternative Control Technology document for NO_x at iron and steel plants (EPA-453/R-94-065) has some limited emissions data. In that report the highest emissions are found for regenerative annealing and galvanizing furnaces. Significant emissions are also found for coke-oven underfiring, sintering, and reheat furnaces. Emission factors that range from 0.021-1.2 lb/MMBtu were found for these sources.

At the time the EPA's ACT NO_x document was published (1994) few emission units found at iron and steel plants had NO_x controls. For many emission unit types, a suitable control technique had not been demonstrated. At that time, this included emission units such as sinter plants, coke ovens, blast furnace stoves, and steelmaking furnaces. Emission processes at iron and steel plants known to have NO_x controls applied at the time of the ACT document publication were reheat furnaces, annealing furnaces, and galvanizing furnaces. Control techniques known to have been applied to these processes are as follows:

Reheat furnaces	Low excess air (LEA)
	LNB
	LNB w/ FGR
Annealing furnaces	LNB
	LNB w/FGR
	SCR
	LNB plus SCR
Galvanizing furnaces	LNB
	LNB w/FGR.

As with most fuel fired NO_x sources, there are two broad categories of NO_x reduction techniques: 1) process controls, including combustion modifications, that rely on reducing or inhibiting the formation of NO_x in the production process (generally through the use of some type of combustion control on the fuel fired emission unit); and 2) post-combustion (secondary) controls, where flue gases are treated to remove NO_x that has already been formed.

For iron and steel plants, six different control technologies or control technology combinations were evaluated for NO_x emissions from fuel fired emission units at iron and steel plants. These technologies are: low NO_x burners, low NO_x burners with FGR, low NO_x burners with SNCR, ultra-low NO_x burners, ultra-low NO_x burners with SCR and SCR. These technologies provide both combustion or post-combustion controls (or a combination of both). Background information on each of these individual technologies (e.g., ULNB) is provided below.

Flue Gas Recirculation

Flue gas recirculation (FGR) uses flue gas as an inert material to reduce flame temperatures. In a typical flue gas recirculation system, flue gas is collected from the heater or stack and returned to the burner via a duct and blower. The flue gas for the FGR system is usually taken from the main flue gas flow downstream of the economizer. A fan (blower) is needed to withdraw the required amount of flue gas. This system is usually called Flue Gas Recirculation (FGR). In some cases, this type system is referred to as "External Flue Gas Recirculation (EFGR)" or "Forced Flue Gas Recirculation". This differentiation is made because sometimes the flue gas for FGR is taken from the flue gas flow upstream of the stack using the forced draft (FD) fan instead of a separate FGR fan. This system is called "Induced Flue Gas Recirculation (IFGR)". In either system, the flue gas is mixed with the combustion air and this mixture is introduced into the burner. The addition of flue gas reduces the oxygen content of the "combustion air" (air + flue gas) in the burner. The lower oxygen level in the combustion zone reduces flame temperatures; which in turn reduces NO_x emissions. When operated without additional controls, the normal NO_x control efficiency range for FGR is 30 percent to 50 percent. When coupled with low-NO_x burners (LNB) the control efficiency increases to 50-72 percent.

Low-NO_x Burners

Low-NO_x burner (LNB) technology utilizes advanced burner design to reduce NO_x formation through the restriction of oxygen, flame temperature, and/or residence time. A LNB is a staged combustion process that is designed to split fuel combustion into two zones, primary combustion and secondary combustion.

Two general types of low NO_x burners exist, staged fuel and staged air. MACTEC utilized the staged fuel design in the cost analysis because lower emission rates can be achieved with a staged fuel burner than with a staged air burner. Staged fuel LNBs separate the combustion zone into two regions. The first region is a lean primary combustion region where the total quantity of combustion air is supplied with a fraction of the fuel. Combustion in the primary region (first stage) takes place in the presence of a large excess of oxygen at substantially lower temperatures than a standard burner. In the second region, the remaining fuel is injected and combusted with any oxygen left over from the primary region. The remaining fuel is introduced in the second stage outside of the primary combustion zone so that the fuel/oxygen are mixed diffusively (rather than turbulently) which maximizes the reducing conditions. This technique inhibits the formation of thermal NO_x, but has little effect on fuel NO_x. Thus staged fuel LNBs are particularly well suited for coal and natural gas fired emissions units which are higher in thermal NO_x than for fuel oils which are higher in fuel NO_x. For fuel oil fired emissions units, the staged air LNBs are generally preferred. By increasing residence times staged air LNBs provide reducing conditions which has a greater impact on fuel NO_x than staged fuel burners. The estimated NO_x control efficiency for LNBs in high temperature applications is 25 percent. However when coupled with FGR or selective non-catalytic reduction (SNCR) these efficiencies increase to 50-72 and 50-89 percent, respectively.

Ultra-low NO_x Burners

These burners may incorporate a variety of techniques including induced flue gas recirculation (IFGR), steam injection, or a combination of techniques. These burners combine the benefits of flue gas recirculation and low-NO_x burner control technologies. Rather than a system of fans and blowers (like FGR), the burner itself is designed to recirculate hot, oxygen depleted flue gas from the flame or firebox back into the combustion zone. This leads to a reduction in the average oxygen concentration in the flame without reducing the flame temperature below temperatures necessary for optimal combustion efficiency. Because of this reduction in temperature, ULNB would likely only be applicable to processes at iron and steel plants that are not temperature dependent, unless the reduction in flame temperature doesn't fall below the required threshold temperature for the process. Reduced oxygen concentrations in the flame have a strong impact on fuel NO_x so ULNBs are an effective NO_x control for fuel firing equipment that fire fuel oil. The estimated NO_x control efficiency for ULNBs in high temperature applications is 50 percent. Newer designs have yielded efficiencies of between 75-85 percent. When coupled with selective catalytic reduction, efficiencies in the range of 85-97 percent can be obtained.

Selective Catalytic Reduction

Selective catalytic reduction (SCR) is a post-combustion NO_x control technology in which ammonia (NH_3) is injected into the post-combustion gas stream in the presence of a catalyst. A catalyst bed containing metals in the platinum family is used to lower the activation energy required for NO_x decomposition. NO_x is removed through the following chemical reaction:

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$

The reaction of NH_3 and NO_x is favored by the presence of excess oxygen. However, the primary variable affecting NO_x reduction is temperature. Optimum NO_x reduction occurs at catalyst bed temperatures of 600–750 °F for conventional (vanadium or titanium based catalysts) and 470–510 °F for platinum catalysts. A high temperature zeolite catalyst is also available; it can operate in the 600–1000 °F temperature range. A given catalyst typically provides optimal performance within ± 50 °F of its design temperature for applications in which flue gas oxygen concentrations are greater than 1 percent. Below this optimum range, the catalyst activity is greatly reduced allowing unreacted NH_3 to slip through (ammonia slip). At temperatures above 850°F ammonia begins to oxidize to form additional NO_x. The

NH_3 oxidation to NO_x increases with increasing temperature. The normal NO_x control efficiency range for SCR is 70 percent to 90 percent.

SCR has been extensively and quite successfully used in a very cost effective manner on coal- and gas-fired utility boilers, industrial boilers, gas turbines and internal combustion diesel engines in the United States. There have been few uses of SCR in the iron and steel industry. At the time the EPA's ACT NO_x document was published, Japanese iron and steel mills had been experimenting with SCR for sinter plants and coke ovens, however these efforts at that time were experimental. As indicated above, SCR has been used with annealing furnaces. There are few other references to the use of SCR for NO_x control for other emission processes at iron and steel plants. MACTEC did find one example usage of SCR for controlling sintering plant exhaust gases. Of particular interest in that example installation was the use of iron ore as the catalyst. The benefit of using iron ore as the catalyst was that unlike other types of catalyst which have a solid waste disposal component, the iron ore can be used directly as a steel making raw material, thus obviating the solid waste disposal issue.

In the SCR process, typically, anhydrous ammonia usually diluted with air or steam is injected into hot flue gases, which then pass through a catalyst bed where NO_x is reduced to N_2 gas and water. As indicated above, the optimum temperature for SCR depends on the catalyst. Thus the exit gas temperatures from some of the processes at iron and steel plants may either be too high or too low, requiring either reheat (if too low) or dilution/quenching (if too high) in order to effectively use SCR. Thus careful consideration should be given on a source-specific basis depending on how raw materials are currently processed.

<u>Selective Non-Catalytic Reduction</u>

In the selective non-catalytic reduction (SNCR) process, urea or ammonia-based chemicals are injected into the flue gas stream to convert NO to N_2 and water. Without the participation of a catalyst, the reaction requires a high temperature range to obtain activation energy. The reaction with urea is as follows:

$$2NO + CO(NH_2)_2 + 1/2\ O_2 \rightarrow 2N_2 + CO_2 + 2\ H_2O$$

The optimum operating temperature for SNCR is 1,600°F to 2,100°F. Under these temperature conditions a significant reduction in NO_x occurs. At temperatures above 2,000°F an alternative reaction occurs and NO_x control efficiency decreases rapidly. The normal NO_x control efficiency range for SNCR is 50 percent to 70 percent. To date there are no known installations of SNCR at iron and steel plants. While there are not any known installations, there should be no reason that SNCR couldn't be used for some operations within an iron and steel plant.

<u>Site-specific Measures</u>

Site-specific measures may also be employed to reduce NO_x emissions. Under this option, facility operators would evaluate the impact of fuels on NO_x emission rates. Generally an evaluation of the impacts of fuels would result in an evaluation of fuel switching. Fuel switching is less likely in the iron and steel industry since much of the fuel used is gaseous, and in several instances is the use of byproduct fuels (e.g., blast furnace gas). Switching to coal or oil may not be an option for iron and steel plants and will likely result in substantial increases in SO_2 emission levels. For this analysis we have not directly considered fuel switching as an alternative to add on controls. However there may be certain processes at specific sites that could see potential cost savings by fuel switching resulting in a single type of control rather than controls for several visibility impairing pollutants. If this option is employed, increases in other pollutant emissions should be compared to the emission reductions achieved for the current fuel in order to identify the best net reduction in visibility impairing pollutants.

SO_2 Emission Control Options

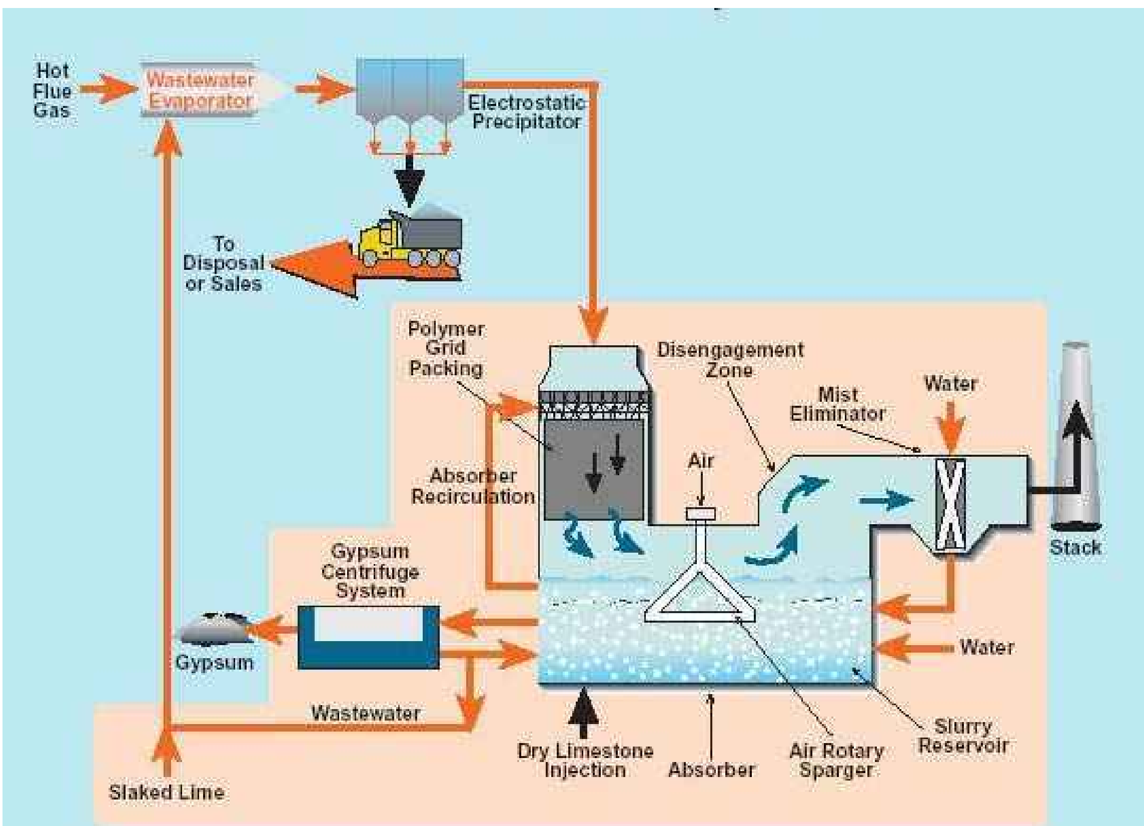
Sulfur dioxide may be generated both from the sulfur compounds in the raw materials and from sulfur in the fuel. The sulfur content of both raw materials and fuels varies from plant to plant and with geographic location. With that said, MACTEC has been unable to find a single instance of installed SO_2 controls at iron and steel plants. Part of the reason for this is because with few exceptions, the fuel fired processes at iron and steel plants generally use a gaseous fuel (natural gas, blast furnace gas, etc.). The main SO_2 emitting processes at the LADCO facilities evaluated in this work were sinter windboxes, coke underfiring, and boilers and process heaters firing either process gas or blast furnace gas. In general (especially for process heaters and boilers), typical SO_2 controls could be utilized for control of SO_2.

The three control technologies evaluated for SO_2 emissions from iron and steel plants were: 1) advanced flue gas desulfurization (AFGD), 2) wet flue gas desulfurization, and 3) dry flue gas desulfurization (spray dryer absorption). A brief description of each of these technologies is provided below.

Advanced Flue Gas Desulfurization

The AFGD process accomplishes SO_2 removal in a single absorber which performs three functions: prequenching the flue gas, absorption of SO_2, and oxidation of the resulting calcium sulfite to wallboard-grade gypsum. Figure 2.2 shows the process flow for an AFGD system.

FIGURE 2.2 ADVANCED FLUE GAS DESULFURIZATION PROCESS FLOW



Incoming flue gas is cooled and humidified with process water sprays before passing to the absorber. In the absorber, two tiers of fountain-like sprays distribute reagent slurry over polymer grid packing that provides a large surface area for gas/liquid contact. The gas then enters a large gas/liquid disengagement zone above the slurry reservoir in the bottom of the absorber and exits through a horizontal mist eliminator.

As the flue gas contacts the slurry, the sulfur dioxide is absorbed, neutralized, and partially oxidized to calcium sulfite and calcium sulfate. The overall reactions are shown in the following equations:

$CaCO_3 + SO_2 \rightarrow CaSO_3 \bullet 1/2\ H_2O + CO_2$
$CaSO_3 \bullet 1/2\ H_2O + 3H_2O + O_2 \rightarrow 2\ CaSO_4 \bullet 2\ H_2O$

After contacting the flue gas, slurry falls into the slurry reservoir where any unreacted acids are neutralized by limestone injected in dry powder form into the reservoir. The primary reaction product, calcium sulfite, is oxidized to gypsum by the air rotary spargers, which both mix the slurry in the reservoir and inject air into it. Fixed air spargers assist in completing the oxidation. Slurry from the reservoir is circulated to the absorber grid.

A slurry stream is drawn from the tank, dewatered, and washed to remove chlorides and produce wallboard quality gypsum. The resultant gypsum cake contains less than 10 percent water and 20 ppm chlorides. The clarified liquid is returned to the reservoir, with a slipstream being withdrawn and sent to the wastewater evaporation system for injection into the hot flue gas ahead of the electrostatic precipitator. Water evaporates and dissolved solids are collected along with the flyash for disposal or sale.

Wet Scrubbing / Flue-Gas Desulfurization

Wet scrubbing techniques are used to control both particulate and SO_2 emissions. Wet scrubbing processes used to control SO_2 are generally termed flue-gas desulfurization (FGD) processes. FGD utilizes gas absorption technology, the selective transfer of materials from a gas to a contacting liquid, to remove SO_2 in the waste gas. Caustic, crushed limestone, or lime are used as scrubbing agents. Our BART screening evaluation assumes that lime is the scrubbing agent. The SO_2 removal reactions for lime are as follows:

$Ca(OH)_2 + SO_2 \rightarrow CaSO_3 \bullet 1/2\ H_2O + 1/2\ H_2O$
$Ca(OH)_2 + SO_2 + 1/2\ O_2 + H_2O \rightarrow CaSO_4 \bullet 2\ H_2O$

The reactions when caustic are used are as follows:

$Na^+ + OH^- + SO_2 \rightarrow NaHSO_3$
$2Na^+ + 2OH^- + SO_2 \rightarrow Na_2SO_3 + H_2O$

The reactions for limestone are presented in the AFGR section.

Caustic scrubbing produces a liquid waste, and minimal equipment is needed. When lime or limestone is used as the reagent for SO_2 removal, additional equipment is needed for preparing the lime/limestone slurry and collecting and concentrating the resultant sludge. Calcium sulfite sludge is watery and it is typically stabilized with fly ash for land filling. The calcium sulfate sludge is stable and easy to dewater. To produce calcium sulfate, an air injection blower is needed to supply the oxygen for the second reaction to occur. The normal SO_2 control efficiency range for SO_2 scrubbers is 80 percent to 90 percent for low efficiency scrubbers and 90 percent to 99 percent for high efficiency scrubbers.

While wet scrubbers have been used successfully in the utility industry for control of SO_2 from boilers, they may require more care when used for an iron and steel plant, since the likelihood of additional contaminants in the fuel source is higher. Calcium sulfate scaling and cementitious buildup when a wet scrubber is used for acid gas control are potential problems when high particulate loadings are found in the gas stream. Many of these problems can be avoided however, if these systems are installed downstream of a high efficiency particulate control device (e.g., fabric filter). Failure of the particulate control device can pose difficult problems for a downstream wet scrubber.

Dry Flue Gas Desulfurization (Spray Dryer Absorption)

Spray dryer absorption (SDA) systems spray lime slurry into an absorption tower where SO_2 is absorbed by the slurry, forming $CaSO_3$/$CaSO_4$. The liquid-to-gas ratio is such that the water evaporates before the droplets reach the bottom of the tower. The dry solids are carried out with the gas and collected with a fabric filter or ESP. When used to specifically control SO_2, the term dry flue-gas desulfurization (dry FGD) may also be used. As with other types of dry scrubbing systems (such as lime/limestone injection) exhaust gases that exit at or near the adiabatic saturation temperature can create problems with this control technology by causing the baghouse filter cake to become saturated with moisture and plug both the filters and the dust removal system. In addition, the lime slurry would not dry properly and it would plug up the dust collection system. However there is some argument in the control community that indicates that some of the SO_2 removal actually occurs on the filter cake. Therefore, dry FGD (spray dryer absorption) may not be technically feasible if exit gas temperatures are not substantially above the adiabatic saturation temperature. For iron and steel plants, these temperatures are likely to be above the adiabatic saturation temperature. If not, a reheater can be applied to the stream to raise the temperature above the adiabatic saturation level.

PM Emission Control Options

Sources of PM at iron and steel plants include (1) sintering, (2) raw material storage, (3) blast furnace, (4) boilers and process heaters, (5) casting and finishing operations, (6) milling, (7) pickling and cleaning operations, and (8) coke production. Some of these sources are PM only sources while others also emit SO_2 and NO_x.

For the LADCO iron and steel sources identified as being BART eligible, the largest emission units are blast furnaces, sintering windboxes, coke underfiring, and scarfing. Particulate control devices for iron and steel plants must be able to clean gases with fairly high dust loadings.

Four general types of control technologies were evaluated for PM emissions from emission units at iron and steel plants: fabric filter (either fixed or attached to traveling hoods), dust collector (cartridge), wet electrostatic precipitator, and dry electrostatic precipitator. All of these control technologies are deemed technically feasible for retrofitting at iron and steel plants, specifically for non-fugitive emission sources.

In addition to the devices identified for non-fugitive emission sources, enclosures were identified as a means of controlling emissions from sintering raw materials handling and from the discharge end of the sintering process. We also look at best management practices as a means of controlling emissions from these two types of sources. Descriptions of each of these controls (fugitive and non-fugitive) are provided below.

Fabric Filter

A fabric filter, or baghouse, is a potential control method for particulate emissions from non-fugitive emission units at iron and steel plants. Many of these facilities are already using fabric filters. The only potential drawback to a fabric filter would be when used in conjunction with a high moisture flue gas stream or with extremely high temperatures. If moisture levels in the flue gas stream are too high then filter caking can occur. A fabric filter, or baghouse, consists of a number of fabric bags placed in parallel inside of an enclosure. Particulate matter is collected on the surface of the bags as the gas stream passes through them. The particulate is periodically removed from the bags and collected in hoppers located beneath the bags. A number of methods are employed to facilitate the removal of particulate from the bags, including shaking, reverse air flow, and pulse air flow. The normal PM control efficiency range for a fabric filter is 95 percent to 99+ percent. A number of emission units at the iron and steel plant emission units identified as potentially subject to BART in the LADCO region already have fabric filters to control particulate emissions.

Dust Collector

Dust collectors are similar to fabric filters in that the air stream is cleaned by passing the stream through a material that acts as a filter. In the case of dust collectors, the filter material is typically a pleated fabric or filter type material. As with fabric filters, the dust is periodically removed, typically by pulsed air jets. The removed particulate is collected in hoppers located beneath the collector. Several factors determine cartridge filter collection efficiency including gas filtration velocity, particle characteristics, filter media characteristics, and cleaning mechanism. The normal PM control efficiency range for a dust collector is in the 99+ percent range.

Cartridge dust collectors do have some limitations however. For example, cartridges are limited in temperature range due to filter media and sealant to approximately 200 ºF. Synthetic non-woven media can be used to a temperature of approximately 400 º F. Higher temperature streams must be cooled to temperatures below these levels using spray coolers or dilution air in order not to damage the cartridges. Minimum temperatures must be kept above the adiabatic saturation temperature in order not to condense materials out. Corrosive streams can also cause problems for the cartridges.

Cartridge filtration systems are generally limited to low flow rate applications. The cartridges also need to operate with a medium pressure drop typically in the range of 100 – 250 mm of water.

Cartridge filtration does have two significant advantages. First the space requirements are significantly lower than those for a baghouse. Second for particles that have low resistivity that would not be handled well by an ESP, cartridges may be an ideal solution.

For iron and steel plants, dust cartridges are likely to only be technically feasible for lower temperature operations or low flow operations.

Dry Electrostatic Precipitator

An electrostatic precipitator (ESP) is a potential control method for particulates from iron and steel plants, especially those from fuel fired equipment. An electrostatic precipitator applies electrical forces to separate suspended particles from the flue gas stream. The suspended particles are given an electrical charge by passing through a high voltage DC corona region in which gaseous ions flow. There are two general types of ESP: wire/plate and wire/pipe types. Further, ESPs come in both wet (see below) and dry configurations. The charged particles are attracted to and collected on oppositely charged collector surfaces. In a dry electrostatic precipitator (DESP) particles on the collector surfaces are released by rapping and fall into hoppers for collection and removal. The normal PM control efficiency range for an ESP is between 90 and 99+ percent with typical values reaching the 98 percent to 99+ percent range.

One of the major advantages of an ESP is that it operates with essentially little pressure drop in the gas stream. As a consequence, energy and operational costs tend to be low (other than electricity to operate the ESP itself). They are also capable of handling high temperature conditions. The major disadvantages of ESPs are their high capital costs and the fact that wire discharge electrodes are a high maintenance item. They are also not well suited for operations that are highly variable due to their sensitivity to gas flow, temperature and particle/gas composition. They also do not handle “sticky” particles well or those that have high resistivities. There may also be the danger of explosion if the gas stream composition is flammable. Relatively sophisticated maintenance personnel are required. Finally, ESPs can take up substantial space in order to achieve the low gas velocities required for efficient particle removal. This may be of concern for retrofit options where space is at a premium.

Wet Electrostatic Precipitator

A wet electrostatic precipitator (WESP) is a potential control method for particulates in boiler flue gas. A WESP operates on the same collection principles as a DESP, and uses a water spray to remove particulate matter from the collection plates. The normal PM control efficiency range for a WESP is 98 percent to 99+ percent. The same advantages and disadvantages that apply to a DESP apply to a WESP with the exception that WESPs can effectively be used to collect "sticky" particles and highly resistive dust. In addition, the wash used in WESPs can also have some control effect on other pollutant gases via absorption and can help condense other emissions due to the cooling of the stream by the wash.

Enclosures

An enclosure is a potential control method for particulate emissions from material handling sources such as mills, grinders, conveyors, etc.. Enclosures, either partial or complete, surround the source as much as possible without interfering with the process operations. Enclosures prevent particulate matter from becoming airborne as a result of disturbance created by ambient winds or by mechanical entrainment resulting from the operation of the source causing the emissions. The normal PM control efficiency range for an enclosure is 50 percent to 100 percent.

Partial enclosures are sometimes combined with wet suppression techniques to provide slightly higher control efficiencies. In general partial enclosures with wet suppression PM control efficiencies are generally towards the top end of the wet suppression alone.

Wet Suppression

Although wet suppression wasn't specifically identified as a potential control method for particulate matter emitted from material handling and other fugitive PM sources at iron and steel plants, certain emission units at LADCO plants already use wet suppression for PM control. In general, wet suppression systems apply either water or water containing a chemical surfactant or foaming agent to the surface of the particulate generating material. The chemical surfactant or foaming agent agglomerates and binds the particulates to the aggregate surface thus eliminating or reducing its emission potential. Care must be taken when using surfactant or foaming agents to insure that their use doesn't compromise the product requirements. In addition, wet suppression can only be used where the final usage of the product does not require a dried product, unless drying occurs as part of the process. The normal PM control efficiency range for wet suppression is 50 percent to 75 percent.

Best Management Practices

Although not specifically identified by MACTEC as a control, PM emissions can also be controlled via "best management practices" (BMP). Best management practices are preventative measures that minimize the release of particulate matter into the environment. Best management practices may include the proper design and maintenance of equipment, good housekeeping, and good operating practices such as using telescopic chutes (basically a form of enclosure) for loading and unloading procedures, limiting drop heights, covering truck beds, and orienting storage piles perpendicularly to prevailing winds to reduce the exposed surface (and thus the emissions). The PM control efficiency range for best management practices varies depending upon the application.

Close scrutiny should be given to these type processes at iron and steel plants to determine if BMP can be used to help control PM emissions at iron and steel facilities.

Effect of the NESHAP on PM Controls

PM controls are specified in the NESHAP for iron and steel plants. Thus if the facility is considered "major" for HAPS, then PM controls will be required for certain sources within iron and steel plants.

The PM emission limits for a sinter windbox exhaust stream are 0.4 pounds per ton (lb/ton) of product sinter for an existing sinter plant and 0.3 lb/ton for a new sinter plant. The final rule limits PM emissions from a discharge end to 0.02 grains per dry standard cubic foot (gr/dscf) for an existing plant and 0.01 gr/dscf for a new plant. The discharge end PM limits are a flow-weighted average when multiple control devices are operated in parallel. A 20 percent opacity limit applies to fugitive emissions from a discharge end at an existing sinter plant; a 10 percent opacity limit applies to a new sinter plant (both are 6-minute averages). The PM emission limits for sinter cooler stacks are 0.03 gr/dscf for an existing plant and 0.01 gr/dscf for a new plant. If the sinter cooler is vented to the same control device as the discharge end, the PM limit is 0.02 gr/dscf for an existing plant and 0.01 gr/dscf for a new plant.

For blast furnaces the PM emission limits for a control device applied to emissions from a casthouse are 0.01 gr/dscf for an existing blast furnace and 0.003 gr/dscf for a new blast furnace. The opacity limits for fugitive emissions from a casthouse are 20 percent for an existing blast furnace and 15 percent for a new blast furnace (both are 6-minute averages).

For primary emissions from a basic oxygen process furnace (BOPF), different PM emission limits apply based on the type of hood system (closed or open). For BOPF with closed hood systems at a new or existing BOPF shop, the PM emission limit is 0.03 gr/dscf, and it only applies during periods of primary oxygen blow. The primary oxygen blow is the period in which oxygen is initially blown into the furnace and does not include any subsequent reblows. For BOPF with open hood systems, the PM emission limits are 0.02 gr/dscf for an existing BOPF shop and 0.01 gr/dscf for a new BOPF shop. These emission limits apply during all periods of the steel production cycle. The steel production cycle begins when the furnace is first charged with scrap and ends 3 minutes after slag is removed. The BOPF limits are a flow-weighted average when multiple control devices are operated in parallel. The PM emission limits for a control device applied solely to secondary emissions from a BOPF are 0.01 gr/dscf for an existing BOPF shop and 0.0052 gr/dscf for a new BOPF shop. Secondary emissions are those not controlled by the primary emission control system, including emissions that escape from open and closed hoods and openings in the ductwork to the primary control system. For the BOPF shop, the PM emission limit for a control device applied to emissions from ancillary operations (hot metal transfer, skimming, and desulfurization) is 0.01 gr/dscf for an existing BOPF shop and 0.003 for a new BOPF shop. The PM emission limits for ladle metallurgy operations are 0.01 gr/dscf for an existing BOPF shop and 0.004 gr/dscf for a new BOPF shop. For the BOPF roof monitor, a 20 percent opacity limit applies to fugitive emissions from the BOPF or BOPF shop operations in an existing BOPF shop. This opacity limit is based on 3-minute averages. For a new BOPF shop housing a bottom-blown furnace, a 10 percent opacity limit applies (6-minute average) except that one 6-minute period not to exceed 20 percent may occur once during each steel production cycle. For a new BOPF shop housing a top-blown furnace, a 10 percent opacity limit applies (3-minute average) except that one 3-minute period greater than 10 percent but less than 20 percent may occur once during each steel production cycle.

VOC Emission Control Options

No controls which specifically targeted VOCs were identified for iron and steel plants. Since there is a NESHAP for iron and steel plants, controls for HAPs (which would also control many VOC emissions) should be sufficient to control VOC emissions from iron and steel plants. Four emission units at ISG-Burns Harbor in Indiana are already controlled for VOC. Two of these units are controlled with simple process enclosures, one with a venturi scrubber and one with a direct flame afterburner. The direct flame afterburner controls stack emissions from the BOF refining cycle, while the venturi scrubber controls emissions from the BOF charging, tapping and slagoff processes. The process enclosures control emissions from the sheet temper mill and the rolling process. Since the VOC emissions should be largely controlled under the NESHAP standards, MACTEC did not develop cost analyses for VOC controls. Total VOC emissions from all LADCO iron and steel plant emission units evaluated for BART are approximately 1000 tons. One third of these emissions are from sinter windbox operations.

The final NESHAP rule requires sinter plants to maintain the oil content of the feedstock at or below 0.02 percent. This limit is based on a 30-day rolling average. There is also an alternative VOC limit of 0.2 pound of VOC per ton (lb/ton) of sinter produced. This limit is also based on a 30-day rolling average. Thus VOC emissions from sintering operations (the largest sources of VOC emissions for LADCO BART facilities) should be controlled as long as the plant is considered “major” for HAPS.

SECTION 3
IRON AND STEEL PLANT BART ENGINEERING SCREENING ANALYSIS

Application of BART Screening to Model Iron and Steel Plant Sources

The first four of the five BART evaluation steps are completed in this section on a model iron and steel plant screening level. The fifth step, selecting BART for the iron and steel plant emission units identified above, takes into account as much source-specific data as possible with respect to control options, costs and any non-air environmental impacts identified for those sources. The analysis of potential BART control technologies must take into account:

- The available retrofit control options,
- Any pollution control equipment in use at the source,
- The costs of compliance with control options,
- The remaining useful life of the facility, and
- The energy and non-air quality environmental impacts of control options.

The BART screening study uses a model iron and steel facility approach, which attempts to represent average operational conditions for an iron and steel plant across the various sources identified in the list of emission units for LADCO. Each iron and steel plant is different, and site-specific issues must be considered in the BART analysis. Site-specific conditions are discussed at the end of this section.

Information Sources

The screening BART analysis used the following primary information sources. Cost information was developed from the following sources:

- Emission control costs are estimated using the capital costs identified in the MACTEC spreadsheet identifying the top three control technologies for each pollutant. A list of references/sources reviewed to develop that list was provided with the spreadsheet. Operating costs were based on the EPA Air Pollution Control Cost Manual.
- Control equipment costs were also obtained from readily available vendor information.
- All control costs were adjusted for inflation using the Consumer Price Index to provide constant dollar estimates.
- Information gaps were addressed by collecting additional cost data from control equipment manufacturers or trade organization (e.g. ICAC).
- Gas and electric costs are based on the U.S. Department of Energy's data for industrial sources (http://www.eia.doe.gov).
- Wastewater treatment costs are obtained from the EPA Air Pollution Control Cost Manual.

In addition to these control cost information sources, MACTEC also used information from vendors, trade associations and the EPA documents "Alternative Control Techniques Document – NO_x Emissions From Iron And Steel Mills," EPA Report # EPA-453/R-94-065, 1994 and "National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Plants - Background Information for Proposed Standards", EPA Report # EPA-453/R-01-005, January 2001 to assist in developing the parameters for the model iron and steel plant. The NESHAP report was particularly useful because one of the primary plants considered in that report was the former Bethlehem Steel plant at Burns Harbor, IN (now ISG-Burns Harbor).

General Control Technology Review Issues

This section outlines important issues that must be taken into account when performing a case-by-case BART evaluation.

Emission Controls vs. Impact on Visibility

In accordance with 40 CFR 51.308(e)(1)(ii)(A) and (B), a BART determination must be based on the following two analyses:

> "*(A) An analysis of the best system of continuous emission control technology available and associated emission reductions achievable for each BART-eligible source …; and*
> *(B) An analysis of the degree of visibility improvement that would be achieved in each mandatory Class I Federal area as a result of the emission reductions achievable from all sources subject to BART located within the region that contributes to visibility impairment in the Class I area, based on the analysis conducted under paragraph (e)(1)(ii)(A) of this section."*

This work is focused strictly on item A, the best system of continuous emission control technology and the associated emission reductions (i.e., the BART engineering analysis). For this analysis, a series of spreadsheets were developed to calculate the costs associated with the various control options evaluated for each model source. The spreadsheets were made flexible enough to handle some source-specific input, enabling the user to recalculate costs using these more source-specific inputs. For this analysis, the emission control costs reported in this section for the model sources include estimates of capital costs, operating costs and cost effectiveness (in units of dollars per ton of pollutant removed). It is important to remember that each pollutant has a different impact on visibility.

As indicated earlier, the majority of SO_2 and NO_x emissions from iron and steel plants are associated with fuel fired operations such as process heaters and boilers along with coke underfiring and sinter (windbox) production. In addition, these sources were substantial contributors to PM emissions. According to the information provided by LADCO, the primary fuels used for process heaters and boilers are natural gas, coke oven gas or blast furnace gas. The spreadsheets prepared were developed assuming that coke oven gas and blast furnace gas were the primary fuels. While coke oven gas and blast furnace gas are similar to natural gas, the SO_2 emissions from these types of emission units required that the SO_2 emission factor for natural gas be raised to account for the higher sulfur levels found in coke oven and blast furnace gases relative to natural gas. The emission factor was raised enough to roughly approximate the mean SO_2 emissions found for all coke oven or blast furnace gas operations at the LADCO iron and steel facilities. Because the average emissions of SO_2 from natural gas fired boilers and process heaters was approximately 10 tons per year, we did not develop cost estimates for natural gas fired units for SO_2. For NO_x, we used a single emission factor (natural gas) to approximate all three gases since natural gas process heaters and boilers generally have higher NO_x emissions than either blast furnace or coke oven gas. We did not perform cost analyses for any secondary fuel types since their emissions were very small.

We also evaluated PM only sources and more simplified cost estimation procedures (e.g., for enclosures) were developed to assess the control costs and emission reductions for these sources.

Site-specific Factors that Affect Control Costs

Although the model sources have been developed to provide a general indication of the technical and economic feasibility of each control technology, a unit-specific BART evaluation must still be performed. A case-by-case evaluation should consider these steps.

- Determine the technical feasibility of listed control equipment for each source subject to BART. Check the technical feasibility analysis to see if analysis is consistent with site-specific conditions. Eliminate all technologies that are infeasible.
- Conduct a control cost analysis on the remaining technologies per the listed control technology rankings. At some point it is likely that site-specific vendor quotes will be required to get accurate cost analysis results. However, one of the reasons we decided to use the model source approach was that if there are a significant number of similar sources, selection of a typical-sized source helps minimize the amount of work needed to perform the cost analysis. Use of the appropriate model source cost analysis in this report as guidance for the cost analysis should provide a relatively good approximation of the potential costs. In addition, most of the cost analyses tools that are available (such as the EPA Control Cost Manual) are generally only good to within about 30 percent. While we have tried to include some specific items that are site-specific, a further review of the list of factors that affect site-specific retrofit costs is advised. From that review, one should identify those factors for which costs will affect control equipment installation at the specific site and include them in the cost analysis. For example, the utility costs used in the spreadsheets should be checked and any appropriate adjustments in the cost calculations made.
- Compare the calculated control costs to the results of the economic affordability analysis to determine which controls are economically feasible and select the appropriate controls as BART. Conduct a site-specific economic analysis of control cost affordability. Site-specific factors can significantly impact the installed costs of pollution control equipment. This is especially true at retrofits of existing equipment, which is the case with BART-eligible sources. Site-specific factors that can impact control costs include:
    - Site preparation work due to removal of existing equipment or modification of existing buildings and structures.
    - Site access for equipment delivery and erection. Existing buildings and structures may limit access to the construction site by cranes and other construction equipment.
    - Additional engineering costs to address piping and duct work tie-ins to existing equipment and structural issues caused by installing new equipment that was not planned for in the original equipment design. Process Safety Management Hazardous Operation (Haz-Op) review requirements and resultant safety system designs could also add to engineering costs.
    - Additional piping and insulation costs to fit new piping and ductwork within existing pipe racks and equipment support structures.
    - Auxiliary equipment that may be needed to accommodate the new control system e.g. blowers, heat exchangers, duct burners, or bypass stacks.
    - Lost production due to process equipment down time while the new equipment is being installed. This generally occurs when piping and duct work are tied in to existing equipment.
- If the facility is located in a relatively remote location, freight costs may be higher than standard estimating factors.
- For larger facilities, installation of control equipment will likely require on-site fabrication, which can increase construction costs.

- Site-specific wastewater treatment costs should be carefully evaluated. The raw materials used in production affect the type of constituents that may be found in wastewater streams. When certain materials are captured by wet scrubbing systems, they will likely affect wastewater quality, and the impact of scrubber blowdown on wastewater management systems should be considered. Compliance with water quality standards also needs to be considered.

Model Source Parameters

The BART screening evaluation uses a model iron and steel plant source to develop cost estimates for pollution control equipment. The model iron and steel plant parameters are listed in Table 3.1. The model source parameters were selected by using information collected as part of the following documents:

1. "Assessment of Control Options For Bart-Eligible Sources: Steam Electric Boilers, Industrial Boilers, Cement Plants, And Paper and Pulp Facilities," Draft Document prepared for NESCAUM, December 2004.
2. "Alternative Control Techniques Document – NO_x Emissions From Iron And Steel Mills," EPA Report # EPA-453/R-94-065, 1994
3. "National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Plants - Background Information for Proposed Standards", EPA Report # EPA-453/R-01-005, January 2001

In addition, information from internet websites related to iron and steel production and actual plant specific data provided by IN for the ISG-Burns Harbor facility were utilized for supplemental information.

Although three fuel types are used for fuel fired equipment at the LADCO iron and steel plants (natural gas, coke oven gas and blast furnace gas), MACTEC used only one gas to produce the cost estimates (and emission reductions). We used a "process gas" that roughly reflected the composite composition of coke oven gas and blast furnace gas, since they were the two predominant gases used as fuel at the LADCO iron and steel plants. The parameters used to estimate costs for typical operations at iron and steel plants are provided in Table 3.1 below.

TABLE 3.1 SUMMARY OF MODEL IRON AND STEEL PLANT OPERATING CHARACTERISTICS.

Emission Unit Type	Flow	Exit Temperature (ºF)
Boilers	264,000	450
Coke underfire	115,000	490
Furnaces	109,000	1200
Sinter windbox	623,100	114

Model Iron and Steel Plant NO_x Control Technology Review

Thermal NO_x from fuel combustion in boilers, furnaces, process heaters, coke underfiring, and sinter production are the primary source of emissions from iron and steel plants. The five steps used to determine BART for the model iron and steel plant are examined below.

1. Identify Available Retrofit Control Technologies
2. Eliminate Technically Infeasible Options
3. Rank Remaining Control Technologies

4. Evaluate Impacts and Document the Results
5. Recommend BART for model source

BART Step 1: Identify All Available Retrofit Control Technologies

The control technologies identified for NO_x are as follows:

- Low-NO_x Burners (LNB)
- Low NO_x burners with FGR (LNB/FGR)
- Low NO_x burners with Selective Non-catalytic Reduction (SNCR)
- Ultra-low NO_x burners (ULNB)
- Ultra-low NO_x burners (ULNB) with Selective Catalytic Reduction (SCR)
- Selective Catalytic Reduction (SCR)

The previous section provided background information on these control technologies.

BART Step 2: Eliminate Technically Infeasible Options

A summary of the technical feasibility analysis is listed in Table 3.2. Details of the analysis for each control technology follow the summary table.

TABLE 3.2 SUMMARY OF TECHNICAL FEASIBILITY FOR IRON AND STEEL PLANT NO_X EMISSIONS

Control Technology Feasibility Determination - Issues That Affect Control Technology Feasibility	
Control Type	**Issues**
Flue Gas Recirculation (FGR)	Minimum temperature requirements Minimum oxygen levels Fan capacity Furnace pressure Burner pressure drop Turndown stability
Low-NO_x Burners	Minimum temperature requirements Minimum oxygen levels Flame length
Ultra-Low-NO_x Burners (ULNB)	Minimum temperature requirements Minimum oxygen levels Flame length
Selective Non-Catalytic Reduction (SNCR)	High temperature requirements Ammonium sulfate formation Ammonia water/waste issues Ammonia slip potential
Selective Catalytic Reduction (SCR)	Limited temperature range for operations Ammonium sulfate formation/fouling Ammonia slip potential

FGR – Infeasible when used by itself

From a strictly technical standpoint, FGR is feasible as long as there is no minimum operational temperature/oxygen requirement for the fuel fired emission unit. FGR may also affect fan capacity, furnace pressure, burner pressure drop, and turndown stability. If these are critical parameters for processes associated with iron and steel production, then FGR may be infeasible. However for this study, we consider FGR by itself to be infeasible because of its generally low control efficiency when used alone. It is considered feasible when used in conjunction with LNB.

Low-NO_x Burners and Low NO_x Burners with FGR – Feasible

LNB are currently in use at some iron and steel facilities so LNB is considered feasible for use at most fuel fired processes within an iron and steel plant. It is even more efficient when coupled with FGR for processes that can tolerate the reduce pressures and other slight operational changes that LNB/FGR cause for fuel fired emission units.

Low-NO_x Burners with SNCR – Potentially infeasible depending upon temperature and sulfur content

There are currently no LNB/SNCR controls active or planned for iron an steel plants. Since LNB is in current use there should be no reason that LNB couldn't be used for iron and steel fuel fired emission units coupled with SNCR. However, the SNCR reagents must be injected into the furnace at 1,600 °F to 2100 °F. Thus if combustion zone temperatures within the fuel fired emission unit do not fall into this range, then adding SNCR to LNB would be infeasible. Many of the fuel fired processes at iron and steel plants have firing temperatures in this range. Additionally, SNCR tends to be less efficient at low NO_x concentrations. Typical values are 200–400 ppm and SNCR operates more efficiently at the middle to upper end of this range. A second issue with SNCR is the potential for formation of ammonium sulfate salts. If sulfur oxides are present in the gas stream they can react with excess ammonia from the SNCR process to form ammonium salts. These materials are very sticky and cause plugging problems if the gas drops below the adiabatic saturation temperature of 350° F. Thus downstream cleaning may be required. Since coke oven gas and blast furnace gas are higher in sulfur than natural gas (but still likely lower than oil or coal), there may not be an issue with SNCR and ammonium sulfate salts. However since there are no active installations of SNCR either alone or in combination with LNB at iron and steel plants, it cannot be completely ruled out. Ammonia also poses potential water quality issues. Ammonia slip released to the atmosphere could contaminate surface waters by deposition. Ammonia may also absorb onto fly ash in some boilers leading to potential issues related to disposal or reuse of the ash. While we have assumed for costing purposes that the model iron and steel fuel fired combustion units have temperatures sufficient for use of this technology, the temperature characteristics of each specific boiler need to be verified in order to definitively say that this technology will work for industrial boilers. We have also assumed (for costing purposes) that sulfate salts won't be a problem but further information would be needed to provide a complete assessment.

Ultra-low NO_x Burners – Feasible

ULNB have similar constraints to FGR. Low-NO_x and ULNB reduce NO_x formation by restricting flame temperature under low oxygen levels. As long as there are no constraints within the facility for flame temperature and/or oxygen levels for the fuel fired emission unit, ULNB should be feasible. In addition, ULNB typically has a longer flame pattern than a standard burner. The impact of longer flames should be evaluated when considering installation of these burners.

Ultra-low NO_x Burners/SCR – Feasible with the correct temperature

The SCR catalysts generally work only in an operating temperature range of 480 °F to 800 °F but will tolerate fairly large swings within that range. Above 850 °F, NH_3 is oxidized. In general, the SCR catalysts may be fouled or deactivated by particulates present in the flue gas. In addition, for iron and steel plants, the presence of alkalies and lime (limestone is used in the sintering process) as well as sulfur dioxide in the exhaust gases is also of concern. These potential fouling problems generally require that the SCR system be installed after the particulate collection device. Recent developments have led to sulfur tolerant SCR catalysts which limit SO_2 oxidation to less than 1 percent. Soot blowers are commonly used to prevent dust accumulation on SCR catalysts.

Since there are current SCR-only removal systems for some types of iron and steel fuel fired emission units, the use of SCR in conjunction with ULNB should be feasible.

SCR – Feasible with the correct temperature

All of the same conditions related to the coupled ULNB/SCR control apply to SCR but since there are current SCR only removal systems for some types of iron and steel fuel fired emission units, the use of SCR is considered technically feasible.

BART Step 3: Rank Remaining Control Technologies

The control technologies evaluated and their control efficiencies are presented in Table 3.3. Control efficiencies for the six controls/control pairs identified as feasible are presented.

TABLE 3.3 CONTROL TECHNOLOGY RANKINGS FOR IRON AND STEEL PLANT FUEL FIRED EMISSION UNITS GENERATING NO_X - CONTROL EFFICIENCY (TYPICAL CONFIGURATIONS LISTED)

Control Technology	Control Efficiency (%)
LNB	40
LNB + FGR	50-72
LNB + SNCR	50-89
ULNB	75-85
SCR	70-90
ULNB + SCR	85-97

BART Step 4: Evaluate Impacts and Document the Results

A discussion of relevant impacts, including (A) economic, (B) environmental, and (C) energy, for each of the technically feasible control technologies is detailed below. The control cost calculation sheets for NO_x are located in Attachment A.

Economic impacts.

This section provides the costs for implementing each of the control technologies that were found to be feasible that are listed in Table 3.3 above. Costs estimated are based on the model iron and steel plant parameters listed above.

The cost for installation of FGR is assumed to be relatively low compared to technologies such as SCR and SNCR. The majority of costs are associated with the ducting and piping, fans and blowers that may be necessary for recirculation of the flue gas. However, FGR is not normally instituted by itself, but in conjunction with LNBs. The cost for installation of new burners is also assumed to be relatively low compared to SNCR and SCR. Thus LNB, LNB with FGR and ULNB options (without additional controls like SCR or SNCR) are likely to be relatively low. Low-NO_x and ULNB burners typically have longer flame patterns than standard burners. The impact of longer flames should be evaluated when considering the cost of installation for these burners.

Like FGR, LNBs are not usually installed by themselves (at least not to achieve BACT or BART levels of controls – they may be installed by themselves to meet other emission limit standards). Our cost estimates were prepared for LNB with FGR and SNCR. Those costs assume a minor amount of work on the fuel fired emission unit and piping revisions will be needed.

The hardware for a SNCR system includes the urea handling system including a vaporizer, storage tank, blower or compressor, and various valves, indicators, and controls; the injectors; transition ductwork; and a continuous emissions monitoring system. Potential site-specific costs not included but that may be necessary are additional particulate removal equipment and ductwork for a control equipment bypass. As mentioned in the technical feasibility step of the evaluation, if the temperature range is not met by the fuel fired emission unit, modifications would be required to increase the gas temperature so that the required reaction temperatures were met. In general waste gas stream reheating is not performed with SNCR since the combustion chamber acts as the reaction chamber. Thus, our costs do not include estimates for reheating the waste gas stream to meet the required temperature levels for the SNCR to operate. This technology is only applicable where the temperatures of the fossil fuel fired emission unit are already adequate for use of this control technology. Additional costs may be necessary for cleaning due to fouling of duct lines if sulfates are available. Each facility will have to determine if this option is feasible on a site-specific basis.

The hardware for a SCR system includes catalyst materials; the ammonia system including a vaporizer, storage tank, blower or compressor, and various valves, indicators, and controls; the ammonia injection grid; the SCR reactor housing (containing layers of catalyst); transition ductwork; and a continuous emissions monitoring system. Costs may vary nominally if aqua ammonia or urea is used instead of anhydrous ammonia. Potential site-specific costs not included but that may be necessary are additional particulate removal equipment and ductwork for a control equipment bypass. If mechanical cleaners are not present, additional gas cleaning may be needed for SCR. Some gas cleaning typically occurs at iron and steel plants. Fuel fired emission units often have bypasses on SCR systems to protect them during startup, shutdown, and malfunction conditions, which could damage the SCR catalyst. As mentioned in the technical feasibility step of the evaluation, if the temperature range is not met by the fuel fired emission unit, modifications would be required to either reduce (for units with temperatures higher than the required catalysts) or increase the boiler gas temperature. Our costs do not include estimates for reheating or providing make up air at lower temperatures to meet the required temperature levels for the SCR to operate. In the case where more heat was required to reach the catalyst temperatures, an actual design would most likely include a duct burner to re-heat the gas stream and a heat exchanger for heat recovery. In this case gas re-heat is required because the exhaust gas is too cool for SCR operating temperature. In addition to a heat exchanger, this option could incur significant costs for duct work and larger air blowers. The potential for fouling the exchanger from dust should also be evaluated. Each facility will have to determine if this option is feasible on a site-specific basis.

The costs presented below are based on the high and low ranges of costs that we found in our literature/vendor review. Wherever possible a high and low cost estimate is presented. In addition, the calculated emission reductions are estimated for each control type/pair based on the high and low ranges found in the literature for these technologies (and the coupled technologies that they are frequently used with, e.g., FGR, SNCR, SCR).

Boilers

The low NO_x burner cost and emission reduction calculations show a reduction of 281 tons from an uncontrolled level of 703. Capital costs range from $543K to $6.94 million, with annual costs between $221K to $1.1 million. Cost per ton of pollutant are between $786 to $3,841. For LNB plus FGR, capital costs are between $891K to $7.8 million, with annual costs between $496K to $1.4 million. Between 352 and 506 tons of pollutant are removed from an uncontrolled level of 703 tons. Cost per ton ranges from $981 to $3,994.

When LNB is coupled with SNCR, the capital cost estimates are between $1.8 to $11.7 million with annual operating costs estimated to be between $976K to $2.3 million. Emission reductions are between 352-626 tons from an uncontrolled level of 703 tons. Cost effectiveness values are between $1,560-6,565 per ton.

ULNB capital costs were estimated to be $2.1 million with annual operating costs of $448K. Pollutant removal was estimated between 528 and 598 tons from an uncontrolled rate of 703 tons. Cost effectiveness estimates were between $750 and $850 per ton.

SCR capital costs ranged from $2-16.8 million. Annual operating costs were estimated between $1.5-3.5 million. Pollutant removal rates were between 492 and 633 tons from an uncontrolled level of 703 tons. Cost effectiveness estimates ranged from $2,444-7,176 per ton. When SCR was coupled with ULNB, the capital costs were between $4-19 million with annual costs of approximately $2-4 million. Removal rates were 598-682 tons per year from uncontrolled levels. Cost effectiveness values ranged from $2,925-6,660.

A summary of all costs for NO_x controls on boilers at iron and steel plants is provided in Table 3.4.

TABLE 3.4 – SUMMARY OF COST ESTIMATES FOR NO_X CONTROLS FOR BOILERS AT IRON AND STEEL PLANTS.

Gas Fired Boiler	**LNB**

Furnaces

In general, costs for furnaces are slightly lower than for boilers due to differences in the heat input and flow rates for boilers and furnaces at iron and steel plants. For LNB, the capital costs for furnaces range from $112K to $1.4 million with annual operating costs of $163-$340K. Emission reductions for furnaces are lower than for boilers due to lower uncontrolled emissions of 145 tons. Emission reductions for LNB for furnaces were 58 tons per year with cost effectiveness values between $2,813-5,867 per ton. When LNB is coupled with FGR, the capital costs range from $446K to $2 million with annual operating costs between $438-666K. Emission reductions are between 73-104 tons from uncontrolled levels. Coste effectiveness is between $4,205-9,186 per ton.

LNB coupled with SCR has capital costs between $382K and $2.4 million. Operating costs range from $486-760K. Emission reductions are 73-129 tons against uncontrolled levels of 145 tons. Cost effectiveness values are $3,766-10,493 per ton.

ULNB capital costs are estimated at $442K with operating cost of $219K. Emission reductions are between 109-123 tons per year resulting in cost effectiveness values of $1,782-2,018 per ton.

SCR capital costs were between $415K-$3.4 million. Annual cost estimates were $987K-$1.4 million. Emission of NOx were reduced between 102-131 tons resulting in cost effectiveness values of $7,566-$13,762 per ton.

Finally ULNB coupled with SCR resulted in capital costs of $857K-$4 million and annual costs between $1.2-1.6 million. Emissions were reduced between 123-141 tons. Cost effectiveness values were between $8,581-13,114 per ton.

A summary of all costs for each control evaluated for furnaces at iron and steel plants is provided in Table 3.5.

TABLE 3.5 – SUMMARY OF COST ESTIMATES FOR NO_X CONTROLS FOR FURNACES AT IRON AND STEEL PLANTS.

Environmental impacts

Because LNB, LNB and FGR and ULNB are simply a change in the combustion character of the burner, there are no known adverse environmental impacts associated with this technology.

Undesirable reactions can occur in either an SCR or SNCR process, including the oxidation of NH_3 and SO_2 to form sulfate salts. These compounds are corrosive and can be deposited on the exhaust duct walls. In addition, ammonium sulfate and ammonium bisulfate condense at temperatures below 400 °F, forming white solids, which will increase particulate emissions if exit temperatures reach this point after passing any particulate devices. Ammonia slip, or un-reacted ammonia, is also a problem with these technologies. Ammonia concentrations in the exhaust gas are typically in the 5-ppm to 10-ppm range. Ammonia can react with sulfur and nitrogen oxides to form fine particulate matter that contributes to haze (exactly what BART is trying to reduce). In addition, storage of anhydrous ammonia can pose some environmental and safety risks associated with the potential for an accidental release. Aqua ammonia and urea may be substituted for ammonia; but these systems have higher capital and operating costs than anhydrous ammonia. Ammonia also poses potential water quality issues. Ammonia slip released to the atmosphere could contaminate surface waters by deposition.

Energy impacts

In FGR systems, since the flame efficiency is affected, the boiler may be less energy efficient than standard burners which could result in a nominal increase in fuel consumption. Some information in the literature suggests that since ULNB are generally a form of FGR, they also may be less efficient than standard burners. However, vendors claim that the new ULNB (and LNB) designs do not lower the boilers fuel efficiency. Thus, a nominal increase in fuel consumption for ULNB may occur.

With respect to SNCR, there may be some minor costs for extra energy for downstream cleaning processes which may be required. Otherwise, energy impacts for SNCR are considered minor.

For SCR, additional natural gas may be required if a duct burner is needed to maintain proper catalyst bed temperatures or additional electrical power to run fans and blowers (either for the added temperatures needed or in the case of cooling of the waste stream).

SO_2 Control Technology Review

The majority of SO_2 emissions at the LADCO BART emission units identified for this study at iron and steel plants come from sintering, coke oven underfiring, furnaces and boilers. This section discusses each step in the BART engineering analysis process for SO_2 controls for these sources.

BART Step 1: Identify Available Retrofit Control Technologies

The top control technologies identified earlier for SO_2 are as follows:

- Advanced flue gas desulfurization
- Wet flue gas desulfurization
- Dry absorption (dry FGD)

Additional information on each of these control technologies was found in Section 2.

BART Step 2: Eliminate Technically Infeasible Options

All of the control technologies identified in step 1 are deemed technically feasible. With that said, MACTEC was not able to identify any current SO_2 controls at iron and steel plants. Thus for the cost analyses, MACTEC considered all controls as feasible.

Fuel switching as an SO_2 control is generally not an option for iron and steel plant sources since they typically are already firing gaseous fuels (e.g., blast furnace gas, coke oven gas, or natural gas). A change to a different fuel could potentially increase the sulfur content of the fuel, even though blast furnace gas and coke oven gas are relatively high in sulfur compared to natural gas.

BART Step 3: Rank Remaining Control Technologies

The technically feasible control technologies and their control efficiencies are presented in Table 3.6.

TABLE 3.6 CONTROL TECHNOLOGY RANKINGS FOR IRON AND STEEL PLANT SO_2 CONTROL.

Control Technology	Control Efficiency (%)
AFGD	95-99.5
Wet FGD	90-99
Dry FGD (Spray Dryer Absorption)	90-95

BART Step 4: Evaluate Impacts and Document the Results

A discussion of relevant impacts, including (A) economic, (B) environmental, and (C) energy, for the technically feasible control technologies is detailed below. A summary of the impacts and the control cost calculation sheets are located in Attachment A.

Economic impacts

For the wet scrubber, the control cost calculations were prepared using lime as the base in the scrubbing liquor. Caustic (NaOH) and limestone are potential alternatives for a scrubber. While lime and limestone require additional equipment for slurry preparation and for solids separation from the sludge generated in the scrubber, lime scrubbers are the most commonly used since lime is plentiful and relatively cheap.

Materials of construction must also be made suitable for caustic, lime, or limestone if existing equipment is modified for wet scrubbing of SO_2. Although not calculated here, wet FGD systems offer some level of particulate control in addition to controlling SO_2.

AFGD systems require additional capital costs for the spargers and blowers necessary to oxidize the waste product to gypsum and for equipment to dewater the product (e.g., centrifuge). However if the commercial grade gypsum can be sold, some of these costs can be offset.

Dry FGD costs were calculated based on the low and high control efficiencies. For dry scrubbers, the flue gas must be cooled to a temperature 10 to 20 degrees above adiabatic saturation. This is typically accomplished using a heat recovery boiler, an evaporative cooler or a heat exchanger. In addition, if the facility does not have one, a particulate removal device is required for removal of the dry materials used to absorb SO_2.

For all scrubbers, costs for an additional or upgraded induced air draft fan to make up for pressure drops within the system may be required. In addition, for wet systems, flue gas reheating may be required, thus a reheater may be necessary.

In preparing the cost estimates, no emission factors were identified for either blast furnace gas or coke oven gas. We used the SO_2 emissions from the LADCO sources to develop a multiplier for the natural gas emission factor from boilers to use in estimating the costs (based on flow, heat input, etc.). The emission factor developed represents a composite gas that is a mix of blast furnace and coke oven gas since these are the two primary fuels used for the four sources evaluated.

Tables 3.7 through 3.10 provide a summary of the estimated costs for each of the SO_2 control systems evaluated for sinter windbox, coke underfiring, boilers, and furnaces, respectively.

Capital costs for sinter windboxes range from $19.8 to 64 million for AFGD, $6.8 – 102 million for wet FGD and $6.4 – 149 million for dry FGD depending upon the control efficiency and whether low or high capital cost assumptions were used.

Annual operating costs for sinter windbox operations range from $7.3 – 15.5 million for AFGD, $7.4-25 million for wet FGD, and $8.2 – 32 million for dry FGD systems.

Cost effectiveness values for AFGD range from about $4,500-10,000 per ton, $4,500-17,000 per ton for wet FGD, and $5,300-$22,000 per ton for dry FGD depending upon the control efficiency.

Similar capital costs are found for coke underfire batteries with the exception of dry FGD. Dry FGD capital costs for coke underfire batteries are slightly lower than those for sinter operations. Annual operating costs for coke underfire battery SO_2 controls were slightly less than those for sinter operations with the range between $4-23 million, depending upon the technology. Cost effectiveness values ranged from $3,000-$17,000 per ton, depending upon the technology.

Capital costs for gas fired boilers and furnaces ranged between $4-122 and $1.2-29 million, respectively depending upon the technology evaluated. Annual costs for SO_2 controls for boilers were between $5-25 million depending upon the control method. For furnaces, these costs were between $2-19 million, depending upon control method. Cost effectiveness values for boilers ranged from $7,600-45,000 and for furnaces between $19,000-206,000.

The costs for SO_2 controls at emission sources at iron and steel plants are high largely due to the fact that these emission sources fire gaseous fuels rather than oil or coal. While the SO_2 emissions are not inconsequential, they typically are not at the same level as for boilers that fire oil or coal. In addition, the MMBtu/hour values used for these sources were significantly higher than those for coal or oil fired boilers.

TABLE 3.7 – SUMMARY OF COST ESTIMATES FOR SINTER WINDBOXES FOR ALL SO_2 CONTROLS.

Environmental impacts

The primary environmental impact from AFGD is byproduct of gypsum. While gypsum is generated as a byproduct, the intent of the AFGD system is to produce gypsum that is commercial grade that can be sold. The primary environmental impact of wet scrubbers is the generation of wastewater and sludge. Waste from wet scrubbers will increase the sulfate and solids loading in the facility's wastewater. This places additional burdens on a facility's wastewater treatment and solid waste management capabilities. These impacts will need to be analyzed on a site-specific basis. If lime or limestone scrubbing is used to produce calcium sulfite sludge, the sludge is water-laden, and it must be stabilized for landfilling. If lime or limestone scrubbing is used to produce calcium sulfate sludge, it is stable and easy to dewater. However, control costs will be higher because additional equipment is required. Scrubber exhaust gases are saturated with water, thus creating a visible plume. Plume visibility may be a local/community concern. Once the exhaust mixes with sufficient air, the moisture droplets evaporate, and the plume is no longer visible.

Disposal of removed material from dry FGD systems is also required and will result in landfill impacts.

Energy impacts

A scrubber operates with a high pressure drop, resulting in a significant amount of electricity required to operate the blower and pump. In addition for some technologies, a flue gas reheater may be required resulting in slightly increased fuel usage.

Iron and Steel Plant Emission Units PM Control Technology Review

The majority of particulate matter emissions from iron and steel plants in the LADCO region emanate from three types of emission units: coke oven underfiring, and furnaces and boilers firing process gases (e.g., coke oven gas or blast furnace gas). Some additional emissions may emanate from other processes such as casting, raw materials handling, etc. however these emissions are typically small. The BART steps for PM control of these types of emission units at iron and steel plants are outlined below.

BART Step 1: Identify Available Retrofit Control Technologies

Identified control technologies available for PM are as follows:

- Dust Cartridge (DC)
- Fabric Filter (Baghouse)
- Dry Electrostatic Precipitator (DESP)
- Wet Electrostatic Precipitator (WESP)

For additional information on these control technologies see Section 2. Each of the steps used in the BART engineering analysis for PM controls on iron and steel plant emission units are discussed below.

BART Step 2: Eliminate Technically Infeasible Options

All PM control technologies identified in step 1 are deemed technically feasible except for dust cartridges. Dust cartridges are not feasible for high temperature (above about 200 F) conditions without using synthetic filter materials. Use of synthetic filter materials in dust cartridges for higher temperature applications is prohibitively expensive given that there are other technologies that are available with similar control efficiencies and lower costs. Thus dust cartridges are likely to be infeasible for PM control for coke underfiring, boilers and furnaces at iron and steel plants.

BART Step 3: Rank Remaining Control Technologies

The third of the five steps in the top-down BART analysis is to rank the remaining control technologies by control effectiveness. The remaining control technologies and their control efficiencies are presented in Table 3.11.

TABLE 3.11 CONTROL TECHNOLOGY RANKINGS FOR IRON AND STEEL PLANT PM CONTROL

Control Technology	Control Efficiency (%)
FF	95-100
DESP	90-100
WESP	90-100

BART Step 4: Evaluate Impacts and Document the Results

A discussion of relevant impacts, including (A) economic, (B) environmental, and (C) energy, for each of the technically feasible control technologies is detailed below. The detailed control cost calculation sheets are located in Appendix A.

Economic impacts

Model source control costs for iron and steel plant PM controls for coke underfiring units are shown in Table 3.12, with costs for gas fired boilers and furnaces shown in Tables 3.13 and 3.14. In general, fabric filters are less expensive in capital costs than DESPs or WESPs, but more expensive for annual operating costs than DESPs.

Capital costs range from $690K-$23 million for coke underfiring, $1.5-53 million for boilers and $654K-22 million for furnaces depending upon the control technology. Annual operating costs are between $336K-5 million for coke underfiring, $687K-12 million for boilers, and $374-6 million for furnaces. Cost effectiveness values range from $2,000-36,000 for coke underfiring, $7,000-150,000 for boilers, and $20,000-200,000 for furnaces. The high cost effectiveness values are largely the result of extremely low particulate emissions from gas fired equipment.

MACTEC did not prepare separate cost estimates for PM controls for other sources at iron and steel plants that can be ducted to existing PM controls, since the majority of emissions for PM are from the three sources that were evaluated. The control cost ranges for PM controls for these sources are sufficiently broad that the likely costs for ducting and extra capacity to handle these emissions would only add minimally to the costs.

PM Fugitive Emission Costs

There are a number of smaller fugitive dust sources or sources that can be controlled using either enclosures or partial enclosures with wet suppression. However, the emissions from these sources for the LADCO facilities were exceptionally small so MACTEC did not develop cost estimates for these sources.

Environmental impacts

For fabric filters, and dry ESPs the main environmental impact is related to disposal of the dry materials collected. The primary environmental impact of wet ESPs is the generation of wastewater and sludge from the washing of the collector. Waste from the scrubber will increase the sulfate and solids loading in the facility's wastewater. This places additional burdens on a facility's wastewater treatment and solid waste management capabilities.

No known environmental impacts are known for the fugitive dust sources.

Energy impacts

Energy requirements (other than the electricity used to power the collector portion of the device) are relatively low. A wet ESP will also require pumps and piping to run the wash water to the ESP.

Iron and Steel Plant VOC Control Technology Review

No specific controls targeting VOC emissions from iron and steel plants were identified. There are currently VOC controls on four emission units at ISG-Burns Harbor in Indiana. Two of these units are controlled with simple process enclosures, one with a venturi scrubber and one with a direct flame afterburner. The direct flame afterburner controls stack emissions from the BOF refining cycle, while the venturi scrubber controls emissions from the BOF charging, tapping and slagoff processes. The process enclosures control emissions from the sheet temper mill and the rolling process. These controls were likely put in place due to the iron and steel NESHAP standards. Since compliance with NESHAP standards basically satisfies the BART requirements, MACTEC did not perform costing for any other VOC controls. Total VOC emissions from all LADCO iron and steel plant emission units evaluated for BART are approximately 1000 tons. One third of these emissions are from sinter windbox operations.

SECTION 4
SOURCE SPECIFIC DATA AND BART RECOMMENDATIONS

This section provides source specific data relative to remaining useful life and existing controls. In addition we provide recommendations for the BART controls on the iron and steel plant emission units identified in the LADCO region.

Remaining Useful Life

MACTEC requested information on remaining useful life of each of the iron and steel plant emission units identified for this BART engineering analysis. We received no information concerning remaining useful life on these units. For the purposes of this analysis, we assumed that the remaining useful life of each emission units was a minimum of at least 10 years and that it was likely that some units would continue to operate for at least 20-30 more years with proper maintenance and upkeep. Thus we found nothing to suggest that the amortization of capital costs or calculation of annual operating costs would be affected by the remaining useful life.

Existing Controls

MACTEC also requested information on any existing controls for the iron and steel plant emission units identified. Table 4.1 shows the information related to current controls. Several of the iron and steel plant emission units already have particulate controls in place, primarily ESPs or fabric filters. No existing controls were identified for either SO_2 or NO_x. No information was provided on the efficiency of these devices.

Fuel Issues

Unlike some other sources, the fuel firing operations at iron and steel plants primarily fire a single fuel, typically some type of gas (e.g., natural, blast furnace or coke oven). Since these fuels are generally low in sulfur (compared to coal or oil), and since NO_x control costs are fairly low for most of these sources, little would be gained from fuel switching. Fuel switching is generally not an option for iron and steel plants.

Table 4.2 shows our preliminary estimates of BART controls for iron and steel plant emission units that may be subject to BART. Our determination of the BART controls selected were based on 1) existing controls, 2) control efficiency levels, 3) costs, and 4) marginal improvements in efficiency. In general we proposed ULNB or LNB for NO_x control primarily because the costs for these controls are significantly lower than other methods and the marginal improvements in control efficiency are generally not as cost effective. Selection of SO_2 controls was significantly more difficult. Estimated costs were high due largely to the MMBtu estimates we developed for the gas fuels. In general we have proposed AFGD or wet FGD for the largest sources. We believe that AFGD is potentially workable for iron and steel plants but there are few AFGD installations on any emission unit other than utility boilers so an alternative may be necessary. However in several cases we have recommended that a source be ducted to a common SO_2 control unit in order to keep costs as low as possible. Determination of the feasibility of this approach requires more source specific information than was available for this study. It may not be practical in all cases.

Finally for most sources we proposed use of existing PM controls (or use of modified existing controls). For those cases where there were no controls we typically recommended either fabric filters or dry ESP since those were most cost effective. That said, there is the very real possibility that existing controls will be all that is required for iron and steel plants if they are subject to the NESHAP requirements. If the final

BART guidelines remain substantially the same as the draft guidelines, NESHAP levels of controls would be considered as satisfying BART. Finally for the sources not easily ducted we recommended partial enclosures, wet suppression or best management practices. PM emissions from these sources are very low and these types of controls represent the most cost effective approach for controlling emissions from these sources. We have not recommended any VOC controls above those already in place for the iron and steel NESHAP.

APPENDIX D. EPA CoST MODEL FROM PROPOSAL FOR STEEL SOURCE CATEGORY

To create the following table, Trinity extracted the following data from the CoST software program which was downloaded from the Community Modeling and Analysis System (CMAS) on May 23, 2022. https://www.cmascenter.org/cost/

The downloaded CoST software program contained data tables showing all available control measures applicable to various pollutants. Trinity first filtered the data tables filtered to only show ones applicable to NOx reduction. The remaining measures were filtered again to those with titles containing the word "Steel". CoST presented the control efficiencies and a summary of the applicable NOx reduction control measures as tables, which were exported to a .csv file. There was no data editing to the CoST export tables, only combining data tables from CoST into the single table here.

Additionally, Trinity obtained the CoST model used for the proposed rule via OneDrive link from Charlie Fulcher (EPA) as described in an email from Robin Langdon (EPA) dated 5/27/2022.
Trinity verified that the CoST model for the proposed rule used the same references as those from the Cost program downloaded on 5/23/2022.

Low Excess Air; Iron & Steel Mills - Reheating	NLEAISRH	NOX	Low Excess Air	Iron & Steel Mills - Reheating	13	1990	1320	2109.54	ptnonipm	Known	10		2006	299|289|281|308	Application: The reduction in NOx emissions is achieved through the use of low excess air techniques, such that there is less available oxygen convert fuel nitrogen to NOx. This control applies to iron & steel reheating furnaces classified under SCC 30300933. Discussion: Low excess air works by reducing levels of excess air to the combustor, usually by adjustments to air registers and/or fuel injection positions, or through control of overfire air dampers. The lower oxygen concentration in the burner zone reduces conversion of the fuel nitrogen to NOx. Also, under excess air conditions in the flame zone, a greater portion of fuel-bound nitrogen is converted to N2 therefore reducing the formation of fuel NOx (ERG, 2000).
Low NOx Burner and Flue Gas Recirculation; Iron & Steel Mills - Galvanizing	NLNBFISGV	NOX	Low NOx Burner and Flue Gas Recirculation	Iron & Steel Mills - Galvanizing	60	1990	580	926.92	ptnonipm	Known	9		2006	289|308|283	Application: This control is the use of low NOx burner (LNB) technology and flue gas recirculation (FGR) to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to iron and steel galvanizing operations with uncontrolled NOx emissions greater than 10 tons per year. Discussion: LNBs are designed to ""stage"" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNBs create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNBs create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002).
Low NOx Burner and Flue Gas Recirculation; Iron & Steel - In-Process Combustion - Process Gas -Coke Oven/ Blast Furnace	NLNBFISIPCG	NOX	Low NOx Burner and Flue Gas Recirculation	Iron & Steel - In-Process Combustion - Process Gas -Coke Oven/ Blast Furnace	55	1990	3190	5098.06	ptnonipm	Known	15			289|283	Application: This control is the use of low NOx burner (LNB) technology and flue gas recirculation (FGR) to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to operations with in-process combustion (Process Gas - Coke Oven/ Blast Furnace) in the Iron & Steel industry with uncontrolled NOx emissions greater than 10 tons per year.
					55	1990	2470	3947.4							
Low NOx Burner and Flue Gas Recirculation; Iron and Steel Production - Annealing or Soaking Pits	NLNBFISPASP	NOX	Low NOx Burner and Flue Gas Recirculation	Iron and Steel Production - Annealing or Soaking Pits	60	1990	750	1198.6	ptnonipm	Known	10		2006	289|283	Application: This control is the use of low NOx burner (LNB) technology and flue gas recirculation (FGR) to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to iron and steel annealing operations with uncontrolled NOx emissions greater than 10 tons per year. Discussion: Soaking pits are a combustion source which can fire natural gas, oil or coal. Emissions of NOx are similar to boilers emissions. LNBs are designed to ""stage"" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNBs create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNBs create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002).
Low NOx Burner and Flue Gas Recirculation; Iron and Steel Production; Blast Heating or Reheating	NLNBFISPBR	NOX	Low NOx Burner and Flue Gas Recirculation	Iron and Steel Production; Blast Heating or Reheating	77	1990	380	607.29	ptnonipm	Known	5		2006	289|308|283	Application: This control is the use of low NOx burner (LNB) technology and flue gas recirculation (FGR) to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to reheating processes in iron production operations with blast heating stoves ant uncontrolled NOx emissions greater than 10 tons per year. Discussion: LNBs are designed to ""stage"" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNBs create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNBs create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002).
Low NOx Burner; Iron & Steel - In-Process Combustion - Natural Gas or Coke Oven Process Gas	NLNBISIPCG	NOX	Low NOx Burner	Iron & Steel - In-Process Combustion - Natural Gas or Coke Oven Process Gas	50	1990	2200	3515.9	ptnonipm	Known	15	204|205		289|283	Application: This control is the use of low NOx burner (LNB) technology to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. This control is applicable to operations with in-process combustion (Natural Gas or Coke Oven Process Gas) in the Iron & Steel industry with uncontrolled NOx emissions greater than 10 tons per year.
					50	1990	1800	2876.65							
Low NOx Burner and Selective Non-catalytic Reduction; Iron & Steel Mills - Annealing	NLNBNISAN	NOX	Low NOx Burner and Selective Noncatalytic Reduction	Iron & Steel Mills - Annealing	80	1990	1720	2748.8	ptnonipm	Known	15		2017	289|308|283	Application: This control is the use of low NOx burner (LNB) technology and selective catalytic reduction (SCR) to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control is applicable to iron and steel annealing operations with uncontrolled NOx emissions greater than 10 tons per year. Discussion: LNBs are designed to ""stage"" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNB's create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNB's create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002). Selective Catalytic Reduction (SCR) has been widely applied to stationary source, fossil fuel-fired, combustion units for emission control since the early 1970s. SCR is typically implemented on units requiring a higher level of NOx control than achievable by SNCR or other combustion controls (EPA, 2002). Like SNCR, SCR is based on the chemical reduction of the NOx molecule. The primary difference between SNCR and SCR is that SCR uses a metal-based catalyst to increase the rate of reaction (EPA, 2002). A nitrogen based reducing reagent, such as ammonia or urea, is injected into the flue gas. The reagent reacts selectively with the flue gas NOx within a specific temperature range and in the presence of the catalyst and oxygen to reduce the NOx. The use of a catalyst results in two advantages of the SCR process over SNCR, the higher NOx reduction efficiency and the lower and broader temperature ranges. However, the decrease in reaction temperature and increase in efficiency is accompanied by a significant increase in capital and operating costs (EPA, 2002). The cost increase is due to the large amount of catalyst required. The SCR system can utilize either aqueous or anhydrous ammonia as the reagent. Anhydrous ammonia is a gas at atmospheric pressure and normal temperatures. There are safety issues with the use of anhydrous ammonia, as it must be transported and stored under pressure (EPA, 2002). Aqueous ammonia is generally transported and stored at a concentration of 29.4% ammonia in water. Today, catalyst formulations include single component, multi-component, or active phase with a support structure. Most catalyst formulations contain additional compounds or sup-ports, providing thermal and structural stability or to increase surface area (EPA, 2002). The rate of reaction determines the amount of NOx removed from the flue gas. The important design and operational factors that affect the rate of reduction include: reaction temperature range; residence time available in the optimum temperature range; degree of mixing between the injected reagent and the combustion gases; uncontrolled NOx concentration level; molar ratio of injected reagent to uncontrolled NOx; ammonia slip; catalyst activity; catalyst selectivity; pressure drop across the catalyst; catalyst pitch; catalyst deactivation; and catalyst management (EPA, 2001).

Low NOx Burner and Selective Catalytic Reduction; Iron & Steel Mills - Annealing	NLNBSISAN	NOX	Low NOx Burner and Selective Catalytic Reduction	Iron & Steel Mills - Annealing	90	1990	4080	6520.4	ptnonipm	Known	15		2017	289|308|283	Application: This control is the use of low NOx burner (LNB) technology and selective catalytic reduction (SCR) to reduce NOx emissions. LNBs reduce the amount of NOx created from reaction between fuel nitrogen and oxygen by lowering the temperature of one combustion zone and reducing the amount of oxygen available in another. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control is applicable to small (<1 ton NOx per OSD) iron and steel annealing operations with uncontrolled NOx emissions greater than 10 tons per year. Discussion: LNBs are designed to ""stage"" combustion so that two combustion zones are created, one fuel-rich combustion and one at a lower temperature. Staging techniques are usually used by LNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNB's create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNB's create a lean combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures (EPA, 2002). Selective Catalytic Reduction (SCR) has been widely applied to stationary source, fossil fuel-fired, combustion units for emission control since the early 1970s. SCR is typically implemented on units requiring a higher level of NOx control than achievable by SNCR or other combustion controls (EPA, 2002). Like SNCR, SCR is based on the chemical reduction of the NOx molecule. The primary difference between SNCR and SCR is that SCR uses a metal-based catalyst to increase the rate of reaction (EPA, 2002). A nitrogen based reducing reagent, such as ammonia or urea, is injected into the flue gas. The reagent reacts selectively with the flue gas NOx within a specific temperature range and in the presence of the catalyst and oxygen to reduce the NOx. The use of a catalyst results in two advantages of the SCR process over SNCR, the higher NOx reduction efficiency and the lower and broader temperature ranges. The rate of reaction determines the amount of NOx removed from the flue gas. The important design and operational factors that affect the rate of reduction include: reaction temperature range; residence time available in the optimum temperature range; degree of mixing between the injected reagent and the combustion gases; uncontrolled NOx concentration level; molar ratio of injected reagent to uncontrolled NOx; ammonia slip; catalyst activity; catalyst selectivity; pressure drop across the catalyst; catalyst pitch; catalyst deactivation; and catalyst management (EPA, 2001).

Selective Catalytic Reduction; Iron & Steel - In-Process Combustion - Bituminous Coal	NSCRISIPCC	NOX	Selective Catalytic Reduction	Iron & Steel - In-Process Combustion - Bituminous Coal	90	1999	3027	4033.16	ptnonipm	Known	20	139		277|205	Application: This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control is applicable to operations with in-process combustion (Bituminous Coal) in the Iron & Steel industry with uncontrolled NOx emissions greater than 10 tons per year.
Selective Catalytic Reduction; Iron & Steel - In-Process Combustion - Natural Gas and Process Gas - Coke Oven Gas	NSCRISIPCG	NOX	Selective Catalytic Reduction	Iron & Steel - In-Process Combustion - Natural Gas and Process Gas - Coke Oven Gas	90	1999	4953	6599.35	ptnonipm	Known	20	139	2017	277|205	Application: This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control is applicable to operations with in-process combustion (Natural Gas and Process Gas - Coke Oven Gas) in the Iron & Steel industry.
Selective Catalytic Reduction; Iron & Steel - In-Process Combustion - Residual Oil	NSCRISIPCO	NOX	Selective Catalytic Reduction	Iron & Steel - In-Process Combustion - Residual Oil	90	1999	4458	5939.82	ptnonipm	Known	20	139	2017	277|205	Application: This control is the selective catalytic reduction of NOx through add-on controls. SCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). The SCR utilizes a catalyst to increase the NOx removal efficiency, which allows the process to occur at lower temperatures. This control is applicable to operations with in-process combustion (Residual Oil) in the Iron & Steel industry with uncontrolled NOx emissions greater than 10 tons per year.
Selective Non-Catalytic Reduction; Iron & Steel Mills - Annealing	NSNCRISAN	NOX	Selective Non-Catalytic Reduction	Iron & Steel Mills - Annealing	60	1990	1640	2620.95	ptnonipm	Known	15	107	2017	289|304|308|283	Application: This control is the reduction of NOx emission through selective non-catalytic reduction add-on controls. SNCR controls are post-combustion control technologies based on the chemical reduction of nitrogen oxides (NOx) into molecular nitrogen (N2) and water vapor (H2O). This control applies to iron and steel mill annealing operations with uncontrolled NOx emissions greater than 10 tons per year, classified under SCC 30300934. Discussion: SNCR is the reduction of NOx in flue gas to N2 and water vapor. This reduction is done with a nitrogen based reducing reagent, such as ammonia or urea. The reagent can react with a number of flue gas components. However, the NOx reduction reaction is favored for a specific temperature range and in the presence of oxygen (EPA, 2002). Both ammonia and urea are used as reagents. The cost of the reagent represents a large part of the annual costs of an SNCR system. Ammonia is generally less expensive than urea. However, the choice of reagent is also based on physical properties and operational considerations (EPA, 2002). Ammonia can be utilized in either aqueous or anhydrous form. Anhydrous ammonia is a gas at atmospheric pressure and normal temperatures. There are safety issues with the use of anhydrous ammonia, as it must be transported and stored under pressure (EPA, 2002). Aqueous ammonia is generally transported and stored at a concentration of 29.4% ammonia in water. Urea based systems have several advantages, including several safety aspects. Urea is a nontoxic, less volatile liquid that can be stored and handled more safely than ammonia. Urea solution droplets can penetrate farther into the flue gas when injected into the boiler, enhancing mixing (EPA, 2002). Because of these advantages, urea is more commonly used than ammonia in large boiler applications.

APPENDIX E. REPRESENTATIVE SCR COST EFFECTIVENESS CALCULATIONS

Summary of U.S. Steel representative unit SCR cost analyses

Unit Type	CSAPR NO_X Limit[1]		Exhaust Temperature °F	Exhaust Flowrate acfm	NO_X Emissions from Reheat tpy	CO_2 Emissions from Reheat tpy	Total Capital Investment 2021$	Total Annual Costs 2021$	NO_X Removed[2] tons/year	Cost Effectiveness 2021$
Annealing Furnace	0.06	lb/MMBtu	500	65,574	2	2,637	4,272,741	1,144,126	40	28,523

1. CSAPR Proposed Rule Table I.B-4 Summary of Proposed NOX Emissions Limits for Iron and Steel and Ferroalloy Emissions Units
2. Assumes a NO_X removal efficiency of 70%.

In order to determine the economic feasibility to retrofit Selective Catalytic Reduction (SCR) technology on existing NOx-emitting sources, Trinity utilized the EPA Air Pollution Control Cost Manual (CCM), Section 4, Chapter 2, Selective Catalytic Reduction, NOx Controls, EPA/452/B-02-001 (https://www.epa.gov/sites/default/files/2017-12/documents/scrcostmanualchapter7thedition_2016revisions2017.pdf). The approach incorporates methodologies from the 6/12/2019 version of the CCM for SCR design parameters and annual costs while utilizing the approach from the 1/2002 CCM for direct and indirect costs. The 2002 manual reflects a more robust determination for direct and indirect costs for SCR as equations incorporate several sensitivity cases, while the 2019 approach is based on the Clean Air Markets Division (CAMD) Integrated Planning Model (IPM) for utility and industrial boilers. The CCM presents cost estimation for industrial boilers via modified IPM equations to replace electricity production ratings with "typical" boiler heat input capacities using boiler net plant heat rate (NPHR). Neither version of the CCM presents cost estimation methodology specific to non-boiler

Critical inputs to the CCM model include heat input rate represented by the total maximum burner heat input to the unit, observed actual exhaust gas temperature and flow rate, actual annual NOx emissions and operating hours for the unit (potential-to-emit has not been utilized for the cost model for a retrofit system), and several market cost data for ammonia, natural gas, and electricity. To employ the CCM methodology for units which do not combust fuel via a burner, such as electric arc furnaces and ladle metallurgy furnaces, the heat input has been calculated utilizing the 40 CFR 75 Table 1 natural gas F-factor and the known exhaust gas flow associated with unit to determine a simulated heat input. Also, SCR operate at optimum control efficiency at approximately 700F, therefore, the approach incorporates reheating the exhaust gas stream via a natural gas-fired duct burner to elevate the current exhaust gas temperature to the target temperature. The combined gas volume from the existing system and natural gas reheat process is utilized for SCR design parameters such as the catalyst area. NOx emissions generated by the reheat process have been quantified via an AP-42 Chapter 1.4 natural gas combustion NOx emission factor, but are not incorporated into the cost effectiveness determination. Further, the cost model includes direct and operating cost associated with a NOx analyzer as determined by EPA's Emission Measurement Center (EMC): Continuous Emission Monitoring Systems

Key output parameters of the cost model include Total Capital Investment (TCI) and cost effectiveness, calculated as the total NOx removed from the exhaust gas at 70% SCR control efficiency divided by the annualized SCR system cost.

SCR Cost Analysis

Detailed SCR Cost Analysis ***(note this is a sample calculation for one process unit - the same steps were used for all U.S. Steel process units to calculate $/ton)***

Parameter	Variable	Calculation	Cost	Units	Reference
Unit Type	Annealing Furnace				
Unit Operating Parameters					
Heat Input Rate	Q_B		121.1	MMBtu/hr	Maximum Heat Input Rate
Exhaust Gas Temperature	T		500	deg F	Average of exhaust gas temperature from *baseline period* at stack outlet (Stack test, DAS data, or conservative estimate)
Exhaust Gas Flow	$q_{fluegas(NoReheat)}$	scfm*(14.7 psi/14.7 psi)*(T+460)/ (68°F+460)	65,574	acfm	Maximum exhaust flowrate from *baseline period* (Stack test, DAS data, or conservative estimate); Assumed dry exhaust gas; Conversion from scfm to acfm based on temperature only (68°F standard temperature; 460 = conversion from °F to Rankine); No significant pressure change assumed (14.7 psi = standard pressure)
Exhaust Gas Flow With Natural Gas Reheat	$q_{fluegas}$	[$q_{fluegas(NoReheat)}$ + $NG_{required}$ / F-factor$_{Natural\ Gas}$ (wscf/Mcf) /t_{SCR}]* (T_{SCR}+460)/ (T+460)	66,789	acfm	Flow volume into SCR catalyst following required reheat of flue gas stream to target SCR operating temperature; Natural Gas wet F-factor (10,610 wscf/MMBtu) per EPA Method 19 (8/3/17); Natural Gas HHV (1,020 MMBtu/10^6 scf) per AP-42 Chapter 1.4 (July 1998); Natural Gas F-factor = 10,610 scf/MMBtu*1,020 MMBtu/10^6 scf* 10^3 Mcf/cf = 10,822 wscf flue gas/Mcf natural gas; Conversion from acfm at process exhaust temperature to acfm at SCR operating temperature based on temperature only (460 = conversion from °F to Rankine) and no significant pressure change assumed (14.7 psi = standard pressure)
Actual Annual NOx Emission Rate	NOx_{annual}		57	tpy	Maximum annual NOx emissions from *baseline period*
Annual Unit Operating Hours	AOH		7,884	hr/yr	Annual operating hours associated with maximum annual NOx emissions from *baseline period*
SCR Control Efficiency	*e*	Maximum efficiency	70	%	EPA/452/F-03-032 SCR Control Technology Fact Sheet
SCR Operating Hours	t_{SCR}	Maximum operation	7,884	hr/yr	Assuming 100% uptime; Operated 100% of time during unit operation
SCR Operating Temperature	T_{SCR}		700	deg F	Optimum SCR operation at 700°F per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Part 2.2.2
Inlet Concentration	NOx_{in}	(NOx_{annual}*2,000 lb/ton) / (Q_B*AOH)	0.12	lb/MMBtu	Calculation at maximum heat input rate.
Outlet Concentration	NOx_{out}	NOx_{in}*(1-*e*)	0.04	lb/MMBtu	Based on SCR control efficiency; Assumes operation at maximum heat input rate.
Available Cost Data					
Capital Cost of Ammonia Catalyst	$CC_{initial}$	(\$8,000/m^3)/(35.3147 ft^3/m^3)	248	\$/ft^3	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, footnote 4; Adjusted from 2010 dollar.
Cost of 19% Ammonia	$C_{NH3solution}$	\$/gal/Den_{NH3}	0.5631	\$/lb	Based on \$0.5631/gallon from Tanner Industries, Inc. budgetary pricing (10/1/2020)
Industrial Natural Gas Price	$Cost_{NG}$		5.5	\$/Mscf	EIA Natural Gas Prices for 2021 - U.S. Total Industrial Price
Industrial Electricity Rate	$Cost_{elect}$		0.1059	\$/kWh	EIA Electricity Data for 2020 - U.S. Total
Chemical Properties and Constants					
Ammonia Solution Density	Den_{NH3}		7.51	lbs/gal	Density of 19% Ammonia Solution
Ammonia Molecular Weight (MW)	$M_{reagent}$		17.03	g/mol	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR
NO_2 MW	M_{NOx}		46.01	g/mol	
Ratio of Equivalent Moles of NH_3 per Mole of Reagent Injected	$SR_{theoretical}$		1	mol NH_3 : mol reagent	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR
Ratio of Equivalent Moles of NH_3 per mole of NOx	SRF		1.05	mol NH_3:mol NOx	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Part 2.3.7
Constant 1	c_1		7	ft	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Part 2.3.12
Constant 2	c_2		9	ft	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Part 2.3.12
SCR Design Data					
Empty Catalyst Layers	n_{empty}		0	layers	Conservatively assumed for lowest capital cost
Nominal Height of Each Catalyst Layer	h'_{layer}		3.1	ft	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Part 2.3.12
Number SCR Chambers	n_{scr}		1	chamber	Conservatively assumed for lowest capital cost
Allowable Slip	Slip		2	ppm	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Part 2.2.2. Minimum range of allowable slip.
Pressure Drop due to Duct	ΔP_{duct}		3	in	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Part 2.5
Pressure Drop due to Catalyst	$\Delta P_{catalyst}$		1	in	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Part 2.5

Detailed SCR Cost Analysis ***(note this is a sample calculation for one process unit - the same steps were used for all U.S. Steel process units to calculate $/ton)***

Parameter	Variable	Calculation	Cost	Units	Reference
Operating Life of Catalyst in Hours	$h_{catalyst}$		20,000	hours	Per 2019 EPA Cost Manual, Sec 4, Chp 2, Part 2.4.2; Assumed average of high-dust SCR as a catalyst layer is typically guaranteed for 16,000 - 24,000 operating hours.
NOx Removal Efficiency	η_{NOx}	$(NOx_{in}-NOx_{out})/NOx_{in}*100\%$	70	%	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.10. Assumes constant removal efficiency without variation of catalyst activity, which decreases over time (2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Part 2.3.10).
Cross Sectional Area of Catalyst	$A_{catalyst}$	$q_{fluegas}$/(16ft/sec x 60 sec/min)	70	ft^2	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.28.
Cross Sectional area of SCR reactor	A_{SCR}	$A_{catalyst}$*1.15 (15% greater than $A_{catalyst}$)	80	ft^2	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.29.
Temp Adjustment	T_{adj}	$15.16-(0.03937*T)+(0.0000274*(T^2))$	2.33	deg F	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.27
Slip Adjustment	$Slip_{adj}$	(1.2835-(0.0567*Slip))	1.17		Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.24
Inlet NOx Adjustment	NOx_{adj}	$(0.8524+(0.3208*NOX_{in}))$	0.89		Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.25
NOx Efficiency Adjustment	η_{adj}	$(0.2869+(1.058*\eta_{NOx}))$	1.03		Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.23
Volume of Catalyst	$Vol_{catalyst}$	$2.81*Q_B*\eta_{adj}*NOX_{adj}*Slip_{adj}*T_{adj}/n_{scr}$	848	ft^3	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.22
Height of catalyst layer	h_{layer}	$Vol_{catalyst}/(N_{layer}*A_{catalyst})+1$	4	ft	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.32
Number of catalyst layers	n_{layer}	$Vol_{catalyst}/(h'_{layer}*A_{catalyst})$	4	layers	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.31
Total Number of catalyst layers	n_{total}	$n_{layer} + n_{empty}$	4	layers	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.33
Height of SCR	h_{scr}	$n_{total}*(C1+h_{layer})+C2$	53	ft	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.34
Mass flow of reagent	$m_{reagent}$	$(NOx_{in}*Q_B*\eta_{NOx}*SRF*M_{reagent})/(M_{NOx})$	4	lb/hr	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.35
Mass flow of solution	m_{sol}	$m_{reagent}/C_{sol}$	21	lb/hr	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.36
Direct Costs					
Catalyst Cost	$f(Vol_{catalyst})$	$Vol_{catalyst}*CC_{initial}$	210,271	$	Calculated
Ammonia Flow Adjustment	$f(NH_3rate)$	$\$411/(lb/hr)*m_{reagent}/Q_B-\$47.3/MMBtu/hr$	-62	$/(MMBtu/hr)	Per 2002 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.38; Adjusted from 1998 dollar
SCR height Adjustment	$f(h_{scr})$	$\$6.12/(ft-MMBtu/hr)*h_{scr}-\$187.9/MMBtu/hr$	250	$/(MMBtu/hr)	Per 2002 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.37; Adjusted from 1998 dollar
Retrofit "Boiler" Adjustment	f(new)	$0/MMBtu/hr	0	$/(MMBtu/hr)	Per 2002 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.40
Bypass Adjustment	f(bypass)	$127/MMBtu/hr	0	$/(MMBtu/hr)	Per 2002 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.42; No Bypass Installed
Ammonia Slip Monitoring	NH_3MON_{cost}	70,000	94,961	$	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Section 2.2.2; Adjusted from 2009 dollar
NOx, O_2, and Flow Monitoring	$NOxMON_{cost}$		221,191	$	NOx analyzer, O_2 analyzer, flow monitor; Cost per EMC: Continuous Emission Monitoring Systems CEMS Cost Model Version 3.0 (3/7/2007); Adjusted from 2007 dollar
Total Direct Cost	DC	$Q_B[3,380/MMBtu/hr+f(h_{scr})+f(NH_3rate)+f(new)+f(bypass)](3,500/Q_B)^{0.35}+f(Vol)+NH_3MON_{cost}+NOxMON_{cost}$	3,016,015	$	Adapted from 2002 EPA Cost Manual, Sec 4, Chp 2 SCR, Equation 2.36; Adjusted from 1998 dollar
Indirect Costs					
Performance Test	PT_{cost}	Budgetary Cost	20,000	$	Testing of Catalyst Core (Engineering Estimate)
General Facilities	GF_{cost}	0.05*DC	150,801	$	Per 2002 EPA Cost Manual, Sec 4, Chp 2 SCR, Table 2.5
Engineering and Home Office Fees	EO_{cost}	0.10*DC	301,602	$	Per 2002 EPA Cost Manual, Sec 4, Chp 2 SCR, Table 2.5
Process Contingency	PC_{cost}	0.05*DC	150,801	$	Per 2002 EPA Cost Manual, Sec 4, Chp 2 SCR, Table 2.5
Total Indirect Installation Costs	B	$PT_{cost}+GF_{cost}+EO_{cost}+PC_{cost}$	623,203	$	Calculated
Project Contingency	C	0.15*(DC+B)	545,883	$	Per 2019 EPA Cost Manual, Sec 4, Chp 2 SCR, Part 2.4.1

Dear Olivia Davidson:

Re: ***Air Plan Disapproval; Illinois, Indiana, Michigan, Minnesota, Ohio, Wisconsin; Air Plan Disapproval; Region V Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, Proposed Rule, Docket ID No. EPA–R05–OAR–2022–0006***

United States Steel Corporation ("U. S. Steel") is submitting these comments pertaining to the above-referenced proposed rule. U. S. Steel has worked diligently with the Illinois Environmental Protection Agency (IEPA), Indiana Department of Environmental Management (IDEM), Michigan Environment, Great Lakes and Energy (EGLE), Minnesota Pollution Control Agency (MPCA), and Ohio Environmental Protection Agency (OEPA) on reducing emissions of nitrogen oxides from our facilities in these states and is committed to doing our fair share by employing practical, technologically feasible and cost-effective means to ensure the areas in which we operate attain and maintain the ozone National Ambient Air Quality Standard (NAAQS); and ensuring that emissions from our sources do not interfere with downwind states' ability to attain and/or maintain the ozone NAAQS. The above-referenced state agencies submitted State Implementation Plans (SIPs) that meet the "interstate transport" provision of Clean Air Act section 110(a)(2)(D)(i)(I), and therefore the SIPs should be approved.

U. S. Steel respectfully notes that in its proposed disapproval, U.S. EPA made some critical errors and, therefore, we believe that in the spirit of cooperative federalism, that U.S. EPA reconsider the State submittals and approve the SIP submittals; or if U.S. EPA still finds deficiencies with the SIPs, that the states be given the opportunity to correct any asserted deficiencies before U.S. EPA proceeds with promulgating a final rule disapproving the SIPs and issuing a Federal Implementation Plan (FIP). It is significant to note that Congress contemplated States be given an opportunity to correct deficiencies with SIPs (before U. S. EPA proceeds with a FIP) when enacting the Clean Air Act. The actions in disapproving the SIP and proceeding with issuing a FIP (even before the SIP is disapproved) runs afoul of the process afforded to States and federal cooperative federalism.

U. S. Steel has several comments regarding the proposed disapproval of the above-referenced SIPs, including:

- The Proposed Disapproval is Not Based upon Accurate Projected Emission Estimates; and the Model Over-Predicts Impacts
- The One Percent Contribution Criterion is Not Appropriate as it is Lower than What U.S. EPA Advised States and it is Lower Than What Can be Supported Based on the Precision of the Modeling
- Even if the SIPs Did Not Satisfy EPA Approval Criteria, States Should be Given the Opportunity to Supplement the SIP Submittal or Otherwise Correct the Asserted Deficiencies Before U.S. EPA finalizes Disapproval of the SIP and Proceeds with a Federal Implementation Plan
- By Simultaneously Proceeding with a FIP, EPA's Proposed Actions Supplant States' Rights and Authority Under the Clean Air Act as Congress Contemplated
- Judicial Review of Any Disapproved SIP Belongs in the Appropriate Circuit Court for the State

The Proposed Disapproval Is Not Based Upon Accurate Projected Emission Estimates and the Model Over-Predicts Impacts

The emission estimates from sources that would be affected by the rule are incorrect; and do not reflect the actual projected emissions. These emission estimates do not include reductions that have been and will be implemented under other actions.

For example, it does not appear that U.S. EPA has considered current and projected emission reductions that have resulted from years of effort by both U.S. EPA and the taconite industry in revising the Federal Implementation Plan (FIP) for regional haze in Minnesota. In addition, undoing or redoing the evaluations and productive efforts that have occurred for over 10 years that have resulted in significant NOx reductions that have been shown to be technologically and economically feasible is inefficient and inappropriate. In sum, these efforts, and most importantly, these reductions must be considered in U. S. EPA's evaluation.

While U. S. Steel disagrees with EPA's proposed threshold of 1 percent, if the data are corrected and incorporated into modeling for Minnesota, it would show that Minnesota's contribution impact is less than EPA's 1 percent proposed "interference" threshold as previously demonstrated by LADCO and U. S. EPA. Second, to the extent that U. S. EPA somehow still finds that emissions from these sources "contribute" or "interfere" with down wind states' ability to attain and maintain the ozone NAAQS, which does not seem plausible, U. S. EPA will need to re-evaluate its costs determinations in the separate ozone transport FIP rulemaking.

The emission estimates from other sources, including those in Illinois, Indiana, Ohio and Michigan – and in particular, emissions from the iron and steel sources in those states, are overstated and are inconsistent with prior state submittals. Finally, separate from the emission estimates, the modeling used in the disapproval over-predicts impacts from the upwind states and sources.

The One Percent Contribution Criterion is Not Appropriate as it is Lower Than EPA Advised States and it is Lower Than What Can be Supported Based on the Precision of the Modeling

U. S. Steel notes that while U.S. EPA may believe the modeling used to support its disapproval of the SIPs is accurate and precise, the accuracy and precision of the modeling does not support an impact threshold of 0.70 ppb. U.S. EPA needs to consider the accuracy and the precision of the modeling when determining an appropriate "interference" threshold. U. S. Steel acknowledges that a model cannot necessarily be "perfect" as U. S. EPA points out, but the U.S. EPA's decisions and impacts to the regulated need to reflect the model's accuracy and precision. U. S. Steel further notes that affected states and the regulated community reasonably relied on 1 ppb threshold that U.S. EPA found to be appropriate; and it is inappropriate for U. S. EPA now to unilaterally disapprove any SIP because in its SIP submittal, the state used a 1 ppb threshold.

Even if the SIPs Did Not Satisfy EPA Approval Criteria, States Should be Given the Opportunity to Supplement the SIP Submittal or Otherwise Correct the Asserted Deficiencies Before U.S. EPA finalizes Disapproval of the SIP and Proceeds with a Federal Implementation Plan

U. S. Steel notes that U.S. EPA's action in disapproving SIPs that were submitted to U.S. EPA years ago and now years later is proposing to disapprove the SIPs and not giving the State an opportunity to supplement the SIP submittal or otherwise correct the asserted deficiencies is inconsistent with Congress' intent for the Federal government and States to work collaboratively on ensuring the NAAQS are maintained.

By simultaneously proceeding with a FIP, EPA's actions supplant states' rights and authority under the clean air act as Congress contemplated

U. S. EPA Cannot Replace Sound State Decisions that Comply with the Clean Air Act with Federal "Judgment" or "Policy". It is well established that States have much latitude in developing and implementing State Implementation Plans (SIPs.) While U.S. EPA may prefer a different approach or alternative, a SIP can only be disapproved when is irrefutably shown to be inconsistent with the Clean Air Act. In the proposed disapproval, U.S. EPA has not shown that the state submittals did not comply with the Clean Air Act. The proposed disapproval of the SIPs is tied closely to EPA's proposed FIP that would have a "one-size fits all" approach that would inappropriately supplant the States' individual authority under the Clean Air Act. Procedurally, U.S. EPA should have afforded the States the opportunity to correct any asserted deficiencies before U.S. EPA proceeded with a FIP. The states were not given such an opportunity.

Judicial Review of Any Disapproved SIP Belongs in the Appropriate Circuit Court for the State

The disapproval of the individual SIPs does not have nationwide effect regardless how U.S. EPA attempts to characterize its proposed action. If finalized as proposed, the rule would result in the disapproval of SIPs for Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin. Each SIP has individual, unique sources, and unique air quality aspects. The SIP submittals are unique to each State. Each state has different types of sources. The issues are unique to each State. The impacts of disapproving these State SIPs are local and regional to the affected states and industries in those states. While U.S. EPA may prefer to have a “one size fits all” approach in developing a FIP to replace these SIPs; this does not change the fact that Congress gave States primary responsibility to adopt State Implementation Plans. The individual State submittals are unique to the individual State and sources; and disapproval of any SIP is presumably unique to the individual State.

For the reasons stated herein, U. S. Steel requests that U.S. EPA approve the SIPs for Illinois, Indiana, Michigan, Minnesota and Ohio; or, in the alternative, provide each State adequate time to review and respond to any deficiencies. We appreciate the U.S. EPA’s careful consideration of these comments.

Sincerely,

David W. Hacker

RE: Comments to EPA's *Air Plan Disapproval; Arkansas, Louisiana, Oklahoma, and Texas; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards*, 87 Fed. Reg. 9798 (February 22, 2022)

Dear Administrator Regan,

United States Steel Corporation ("U. S. Steel") appreciates the opportunity to submit the following comments on behalf of our corporation and all subsidiaries to the United States Environmental Protection Agency ("EPA"). U. S. Steel Corporation started in 1901 and has evolved and grown with America over the years. Our most recent growth can be seen in Arkansas with our mini-mill construction announcement in February of this year. As a corporation operating in Arkansas, U. S. Steel is a party impacted by this rule and as such, U. S. Steel provides comments on EPA's *Air Plan Disapproval; Arkansas, Louisiana, Oklahoma, and Texas; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards* (Proposal). U. S. Steel also supports the Arkansas Environmental Federation ("AEF") comments submitted regarding the Proposal and incorporates those comments by reference.

The Arkansas Department of Energy and Environment, Division of Environmental Quality ("DEQ") is best situated to review, evaluate and address the impacts of the NAAQS on Arkansas businesses and industries and developed the SIP complying with the NAAQS requirements. DEQ developed an appropriate and approvable SIP for the State of Arkansas and thus incorporates by reference the comments submitted on April 22, 2022, by the DEQ ("DEQ Comments") in Docket ID No. EPA-RO6-OAR-2021-0801. U. S. Steel requests that EPA reevaluate the Arkansas SIP based upon all information submitted, including DEQ Comments, and approve the Arkansas SIP.

DEQ has expended an enormous amount of time and worked diligently to meet the NAAQS for ozone. DEQ worked to develop the information necessary to formulate the SIP, developed a proposed plan, and undertook the required state-rulemaking and legislative action. DEQ also worked collaboratively with EPA Region 6. Numerous discussions were held by DEQ and EPA Region 6 to inform DEQ's development of an appropriate SIP. DEQ responded to questions and comments from EPA Region 6 to develop the SIP. Additionally, DEQ developed additional information in response to EPA Region 6's comments as a part of a collaborative process that EPA has now abandoned.

EPA has a role in the SIP process. However, that role should be a narrow one that gives deference to the state pursuant to the cooperative federalism system established under the Clean Air Act ("CAA"). EPA's proposal to disapprove Arkansas's interstate transport SIP for the 2015 ozone NAAQS[1] goes beyond the authority given to EPA by the CAA. State's, such as Arkansas, are given discretion under the CAA to address NAAQS through appropriate plans.[2] EPA's proposal oversteps the agency authority under the CAA. The Arkansas SIP should be re-evaluated by EPA solely on the basis of whether Arkansas has met the applicable CAA requirements. EPA should not use the SIP disapproval process to try to create a "national ozone transport policy".

EPA's Proposal to disapprove Arkansas's SIP while also promulgating a FIP is not the proper timing of rulemaking on this issue. EPA not allowing DEQ to submit revisions to the SIP, this action impairs the state's ability to make state specific analyses regarding over-reach on controls by EPA. DEQ should be permitted time to analyze, address and/or correct any deficiencies identified by EPA before finalizing a FIP. Although EPA might generally have the authority under Section 7410(c)(1)(B) to issue a FIP at any time prior to the 2-year deadline after disapproval (EME Homer S.Ct., 134 S.Ct. 1584 (2014)), nevertheless, CAA Section 7410(c)(1) contemplates that a state would be provided time to correct any deficiency and that EPA has the discretion to allow up to two years for correction of any deficiency. EPA's determination about whether a FIP should be promulgated immediately as to a specific state should be based on a state-specific analysis since a State may bring a particularized, as-applied challenge to a nationwide or regional transport rule (EME Homer on remand, 795 F.3d 118 (D.C. Cir. 2015). EPA should not move to finalize the proposed FIP with respect to Arkansas until DEQ has been provided adequate time to review and respond.

[1] *See* 42 U.S.C. § 7410(a) (requiring States to submit plans to implement, maintain, and enforce NAAQS); *see also Com. of Va. v. EPA*, 108 F.3d 1397, 1407 (D.C. Cir.), decision modified on reh'g, 116 F.3d 499 (D.C. Cir. 1997) (stating that the CAA "expressly gave the states initial responsibility for determining the manner in which air quality standards were to be achieved.").

[2] *See Union Elec. Co. v. EPA*, 427 U.S. 246, 250 (1976) ("Each State is given wide discretion in formulating its plan."); *Train v. NRDC*, 412 U.S. 60, 79 (1975) ("[EPA] is relegated by the [Clean Air] Act to a secondary role in the process of determining and enforcing the specific, source-by-source emission limitations which are necessary if the national standards it has set are to be met."); *Fla. Power & Light Co. v. Costle*, 650 F.2d 579, 587 (5th Cir. 1981) ("The great flexibility accorded the states under the Clean Air Act is further illustrated by the sharply contrasting, narrow role to be played by EPA.").

EPA claims that the appropriate venue for challenges to EPA's final action on the interstate transport SIPs for Louisiana, Arkansas, Texas, and Oklahoma is the U.S. Court of Appeals for the District of Columbia Circuit ("D.C. Circuit").[3] Unser Section 307(b)(1) of the CAA, to determine venue for challenges to EPA actions, the relevant questions are whether the action is: (1) a nationally applicable action; (2) a locally or regionally applicable action; or (3) a locally or regionally applicable action based on a determination that has nationwide scope or effect.[4]

EPA attempts to claim that the SIP, if finalized, would be "nationally applicable" because it would address four states and "would apply uniform, nationwide analytical methods, policy, judgments and interpretation with respect to the same CAA obligations." [5] EPA's statements and stated reasoning are not adequate to make this a "nationally applicable" decision and would not be consistent with other SIP decisions. Specifically, this approach is inconsistent with EPA's SIP decisions regarding Florida, Georgia, North Carolina, and South Carolina [6] which involved four states and two Federal judicial circuits and relied on the same EPA analysis. EPA did not determine it was "nationally applicable" and determined that judicial review must be filed in the United States Court of Appeal for the appropriate circuit. [7]

EPA attempts to claim that the SIP rulemaking for ozone transport for Arkansas, Louisiana, Texas and Oklahoma will be nationally applicable and have a nationwide scope. However, EPA's proposed action is one that will be locally or regionally applicable with all the states in the same region and only impacts the four states. Petitions for review of EPA's final action regarding the interstate ozone transport SIPs may be brought only in the court of appeals for the appropriate circuit. Any Petition for Review of EPA's final action with respect to Arkansas's SIP, should be brought the U.S. Court of Appeals for the Eighth Circuit.

For the reasons set forth above and those provided in the comments filed by DEQ and AEF, U. S. Steel requests EPA approve the Arkansas SIP, or in the alternative, provide DEQ adequate time to review and respond to any deficiencies identified by EPA through a SIP Call.

U. S. Steel appreciates the opportunity to provide comments on the Proposal to disapprove the SIP. If you have any questions or should you need additional information, please do not hesitate to contact me at 479-200-9743 or kjones@uss.com.

Sincerely,

KAJ

Administrator Michael Regan
C/O EPA Docket Center (EPA/DC)
Docket ID No. EPA-HQ-OAR-2021-0668
U.S. Environmental Protection Agency

Submitted via Federal eRulemaking Portal (Regulations.gov)

RE: Request for Extension of Comment Period, "Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Primary Ozone National Ambient Air Quality Standard" Docket No. EPA-HQ-OAR-2021-0668. *Federal Register* 87 Fed. Reg. 20,036 (April 6, 2022).

Dear Administrator Regan,

United States Steel Corporation ("U. S. Steel") respectfully requests at least an additional 60-day extension for the comment period on the proposed "Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Primary Ozone National Ambient Air Quality Standard" Docket No. EPA-HQ-OAR-2021-0668. *Federal Register* 87 Fed. Reg. 20,036 (April 6, 2022) ("Proposed FIP"). U. S. Steel appreciates the slight extension of the comment period, but more time is needed. The original comment deadline of June 6, 2022 was extended briefly by EPA however the new EPA comment deadline of June 21, 2022 still does not provide adequate time for the complexity and breadth of the proposed rule. Commenters should have until at least August 8, 2022, to provide meaningful and substantive technical and legal comments on this Proposed FIP.

The Proposed FIP is unparalleled in terms of geography, scope, industry, and impacted emissions units, the breadth of impact and all the supporting information requires an in-depth review of EPA's work. A thorough and proper review would include at minimum working through the photochemical modeling analyses and its underlying data inputs. The data needed to even conduct such a review was not provided by EPA at the time of publication of the Proposed FIP and must be requested from EPA. Many requests for the data have been made by various interested parties and the role out of information is taking days and even weeks – which further reduces the time available for any meaningful review during the comment period. Even if the data is provided timely there is not sufficient time to review and do independent analyses and modeling – for multiple state and dozens of facilities - prior to the June 21, 2022, comment deadline.

To allow appropriate time for interested parties to provide meaningful review and comment on such a complex rule requires extensive time and manpower. The proposed FIP is 180 pages the online docket contains 191 groups of records including dozens of documents and spreadsheets. This review and work necessary is even more challenging for corporations who have multiple states and emission impacts to review. Not to mention the simultaneous running of comment periods for the various SIP Disapproval dockets, like for instance Docket No. EPA-R06-OAR-2021-0801which U.S. Steel also commented on during this time.

Throughout the Proposed FIP it seems as if EPA intends to provide critical data only upon request. The data is essential to fully evaluate all of EPA's assessments related to Non-EGU emissions, control costs, and air quality impacts. The EPA Screening Assessment of Potential Emissions Reductions, Air Quality Impacts and Costs from Non-EGU Emissions Units for 2026 (Non-EGU Screening Assessment) refers and cites extensively to model inputs, codes and Control Strategy Tool ("CoST") run data that no one has unless they specifically request the data from EPA. The Proposed FIP relies heavily on this information, and it should be available for review and scrutiny by any interested stakeholder.

Since the data required to consider this vast rule is not already provided U. S. Steel requests the following be provided:

1. The air quality contribution data that EPA used to identify potentially impactful industries in 2023 and the R code that processed these data; [1]
2. The CoST run results and the R code that generated the curves EPA used for identifying a cost threshold to evaluate emissions reductions in potentially impactful industries in 2023; [2]
3. The maximum emission reduction CoST run results that EPA used to assess Non-EGU emission reduction potential and estimated air quality impact in potentially impactful industries in 2023;[3]
4. The 2023 state-receptor specific Revised CSAPR Update ("RCU") ppb/ton values, the RCU calibration factors used in the air quality assessment tool ("AQAT") for control analyses in 2023, the R code that processed the CoST run results using the maximum emission reduction algorithm, and the summaries of the air quality improvements; [4]
5. The 2023 state-receptor specific RCU ppb/ton values, the RCU calibration factors used in the AQAT for ozone for control analyses in 2023, and the R code that processed the CoST run results that EPA used for its impactful boiler assessment;[5]

[1] Non-EGU Screening Assessment at 3, FN9.
[2] *Id* at 4, FN12.
[3] *Id* at 5, FN14.
[4] *Id* at 5, FN16.
[5] *Id* at 6, FN20.

6. The R code that processed the CoST run results, the sector-specific (non-EGU specific) ppb/ton values, and the 2026 AQAT calibration factors used to prepare the Non-EGU Screening Assessment tables on estimated emissions reductions, maximum PPB improvement, and costs. [6]

The expectation of EPA is that stakeholders to review volumes data, wait for data requests to be fulfilled, evaluate 53 distinct elements of the Proposed FIP and then look at "all aspects of the proposal." Expecting stakeholders to complete all of this within the currently allotted 75-days is not feasible or realistic. Simply, a proper level of review, analyses and response cannot be accomplished in this limited timeframe.

The timeframe for comments as currently proposed by EPA does not allow for or promote public engagement in the rule making process. Stakeholders must be afforded more time to develop and submit data and analyses that should be essential considerations for the EPA promulgation of well-supported and lawful rule. This is especially true in this instance, as a preliminary review of some of the data that time has afforded so far reveals critical errors in EPA's analyses which warrants a more thorough review of all aspects of the rule to ensure EPA's decision-making process is based upon sound science and reasoning.

U. S. Steel requests EPA provided an additional extension of the comment period for the Proposed FIP by at least an additional 60 days. Any shorter comment period simply does not provide stakeholders a meaningful opportunity to review, evaluate and comment.

U. S. Steel appreciates the consideration of this request. If you have any questions or wish to discuss, please do not hesitate to contact me at 479-200-9743 or kjones@uss.com.

Sincerely,

Kendra A. Jones, Esq.

Motion to Stay, *United States Steel Corporation v. EPA*, *et al.*, Case No. 23-1207 (D.C. Cir.)

Exhibit E

Screening Assessment of Potential Emissions Reductions, Air Quality Impacts, and Costs from Non-EGU Emissions Units for 2026 (Feb. 28, 2022)

TECHNICAL MEMORANDUM

TO: Docket for Rulemaking, "Proposed Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standards" (EPA-HQ-OAR-2021-0668)
DATE: February 28, 2022
SUBJECT: Screening Assessment of Potential Emissions Reductions, Air Quality Impacts, and Costs from Non-EGU Emissions Units for 2026

Note: EPA originally posted this document on March 11, 2022. This document, posted on March 29, 2022, corrects inadvertent errors referencing a filename on page 9 and in Table 5 on page 16.

I. Introduction

The EPA developed an analytical framework to facilitate decisions about industries, emissions unit types, and cost thresholds for including emissions units in the non-electric generating unit "sector" (non-EGUs) in a federal implementation plan (FIP) proposal for the 2015 ozone national ambient air quality standards (NAAQS) transport obligations. Using this analytical framework, we prepared a screening assessment for the year 2026.

This memorandum presents the analytical framework and summarizes the screening assessment the EPA prepared to identify industries and emissions unit types to include in proposed rules to obtain NOx emissions reductions from non-EGUs. Sections VII.A.2. and VII.C. of the proposal preamble include discussions of the non-EGU NOx emissions limits, compliance timing, and other related-rule requirements for the industries and emissions unit types identified through the screening assessment.

The remainder of this memorandum includes the following sections:

- II. Background on Analytical Framework
- III. The Analytical Framework
  - Step 1 -- Identifying Potentially Impactful Industries in 2023
  - Step 2a -- Identifying a Cost Threshold to Evaluate Emissions Reductions in Potentially Impactful Industries for 2023
  - Step 2b -- Assessing Non-EGU Emission Reduction Potential and Estimated Air Quality Impacts in Potentially Impactful Industries in 2023
  - Step 2c – Refining Tier 2 by Identifying Potentially Impactful Boilers in 2023
- IV. Modifying the Analytical Framework for the Screening Assessment for 2026
- V. Screening Assessment Results for 2026 -- Estimated Total Emissions Reductions, Air Quality Improvements, and Annual Total Costs for Emissions Units in Tier 1 Industries and Impactful Boilers in Tier 2 Industries
- VI. Request for Comment and Additional Information

II. Background on Analytical Framework

The number of different industries and emissions unit categories and types, as well as the total number of emissions units that comprise the non-EGU "sector"[1] makes it challenging to define a single method to identify impactful emissions reductions. We incorporated air quality information as a first step in the analytical framework to help determine potentially impactful industries to focus on for further assessing emission reduction potential, air quality improvements, and costs. Given the lengthy decision-making and analysis schedules for the FIP

[1] The non-EGU "sector" includes non-electric generating emissions units in various manufacturing industries and does not include municipal waste combustors (MWC), cogeneration units, or <25 MW EGUs. For a discussion of MWCs, cogeneration units, and EGUs <25 MW, see Section VI.B.3. of the proposed rule preamble.

proposal, we developed the analytical framework using inputs from the air quality modeling for the Revised CSAPR Update (RCU) for 2023[2], as well as the projected 2023 annual emissions inventory from the 2016v2 emissions platform that was used for the air quality modeling for the proposed rule.

Using the RCU modeling for 2023, we identified upwind states linked to downwind nonattainment or maintenance receptors using the 1% of the NAAQS threshold criterion, which is 0.7 ppb (1% of a 70 ppb NAAQS). In 2023 there were 27 linked states for the 2015 NAAQS: AL, AR, CA, DE, IA, IL, IN, KY, LA, MD, MI, MN, MO, MS, NJ, NY, NV, OH, OK, PA, TN, TX, UT, VA, WI, WV, and WY.

To analyze non-EGU emissions units, we aggregated the underlying projected 2023 emissions inventory data into industries defined by 4-digit NAICS.[3] Then for the linked states, we followed the 2-step process below:

1. **Step 1** -- We identified industries whose potentially controllable emissions are estimated, by applying the analytical framework, to have the greatest ppb impact on downwind air quality, [4] and
2. **Step 2** – We determined which of the most impactful industries and emissions units had the most emissions reductions that would make meaningful air quality improvements at the downwind receptors at a marginal cost threshold we determined using underlying control device efficiency and cost information.

Additional details on these steps are presented in the Section III below.

Finally, the EPA concluded, based on the most recent information available from the CSAPR Update Non-EGU TSD,[5] that controls on all of the non-EGU emissions units cannot be installed by the 2023 ozone season.[6] As such, we modified the analytical framework slightly and applied it for a screening assessment estimating potential emissions reductions, air quality improvements, and costs for the year 2026.

III. The Analytical Framework

Step 1 - Identifying Potentially Impactful Industries in 2023

The analytical framework starts with identifying industries whose potentially controllable emissions may contribute to downwind receptors. To identify industries that have large, meaningful air quality impacts from potentially controllable emissions, we estimated air quality contribution by 4-digit NAICS-based industry for 2023. To estimate the contributions by 4-digit NAICS at each downwind receptor, we used the 2023 state-receptor specific RCU ppb/ton values and the RCU calibration factors used in the air quality assessment tool (AQAT) for control analyses in 2023.[7]

[2] We used the RCU air quality modeling for this screening assessment because the air quality modeling for the proposed rule was not completed in time to support this assessment.
[3] North American Industry Classification System (https://www.census.gov/naics/).
[4] To identify industries, we reviewed emissions units with >= 100tpy emissions units in the 2023 inventory in those industries in the upwind states.
[5] Final Technical Support Document (TSD) for the Final Cross-State Air Pollution Rule for the 2008 Ozone NAAQS, Assessment of Non-EGU NO_X Emissions Controls, Cost of Controls, and Time for Compliance Final TSD ("CSAPR Update Non-EGU TSD"), August 2016, available at *https://www.epa.gov/csapr/assessment-non-egu-NOx-emission-controls-cost-controls-and-time-compliance-final-tsd*.
[6] Note that information on control installation timing as detailed in the 2016 CSAPR Update Non-EGU TSD is not complete or sufficient to serve as a foundation for timing estimates for this proposed FIP.
[7] The calibration factors are receptor-specific factors. For the RCU, the calibration factors were generated using 2016 base case and 2023 base case air quality model runs. These receptor-level ppb/ton factors are discussed in the Ozone Transport

We focused on assessing emissions units that emit >100 tpy of NOx.[8] By limiting the focus to potentially controllable emissions, well-controlled sources that still emit > 100 tpy are excluded from consideration. Instead, the focus is on uncontrolled sources or sources that could be better controlled at a reasonable cost. As a result, reductions from any industry identified by this process are more likely to be achievable and to lead to air quality improvements.

Based on the industry contribution data, we prepared a summary of the estimated total, maximum, and average contributions from each industry and the number of receptors with contributions >= 0.01 ppb from each industry. We evaluated this information to identify breakpoints in the data, as described in detail in Appendix A. These breakpoints were then used to identify the most impactful industries to focus on for the next steps in the analysis.[9]

A review of the contribution data indicated that we should focus the assessment of NOx reduction potential and cost primarily on four industries. These industries each (1) have a maximum contribution to any one receptor of >0.10 ppb and (2) contribute >= 0.01 ppb to at least 10 receptors. We refer to these four industries identified below as comprising **"Tier 1"**.

- Pipeline Transportation of Natural Gas
- Cement and Concrete Product Manufacturing
- Iron and Steel Mills and Ferroalloy Manufacturing
- Glass and Glass Product Manufacturing

In addition, the contribution data suggests that we should include five additional industries as a second tier in the assessment. These industries each either have (1) a maximum contribution to any one receptor >=0.10 ppb but contribute >=0.01 ppb to fewer than 10 receptors, or (2) a maximum contribution <0.10 ppb but contribute >=0.01 ppb to at least 10 receptors. We refer to these five industries identified below as comprising **"Tier 2"**.

- Basic Chemical Manufacturing
- Petroleum and Coal Products Manufacturing
- Metal Ore Mining
- Lime and Gypsum Product Manufacturing
- Pulp, Paper, and Paperboard Mills

Policy Analysis Final Rule TSD found here: https://www.epa.gov/sites/default/files/2021-03/documents/ozone_transport_policy_analysis_final_rule_tsd_0.pdf.

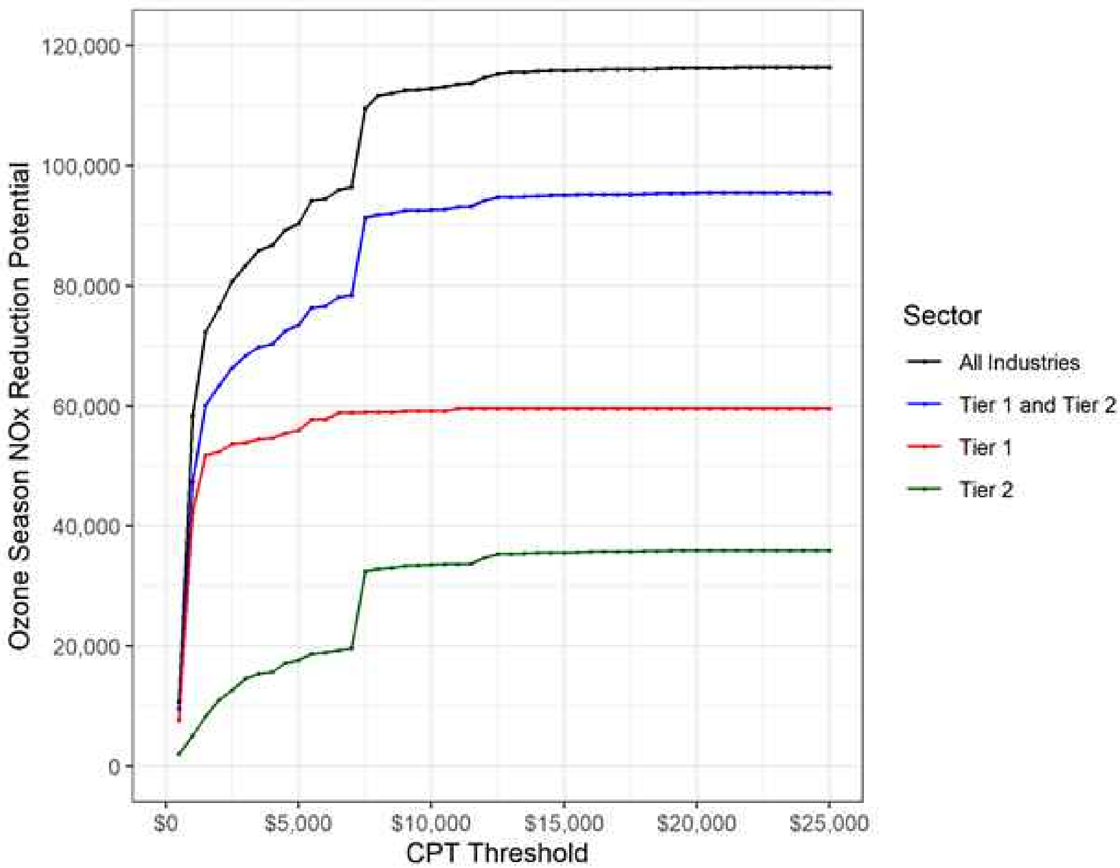
[8] In the non-EGU emission reduction assessment prepared for the Revised Cross State Air Pollution Rule Update (https://www.regulations.gov/document/EPA-HQ-OAR-2020-0272-0014), we reviewed emissions units with >150 tpy of NOx emissions. In this screening assessment, we broadened the scope to include emissions units with >=100 tpy of NOx emissions. We believe that emissions units that are smaller may already be controlled and reductions from these smaller units are likely to be more costly.

[9] The air quality contribution data and the R code that processed these data are available upon request.

Step 2a - Identifying a Cost Threshold to Evaluate Emissions Reductions in Potentially Impactful Industries for 2023

To identify an annual cost threshold for evaluating potential emissions reductions in the Tier 1 and Tier 2 industries, the EPA used the Control Strategy Tool (CoST)[10], the Control Measures Database (CMDB)[11], and the projected 2023 emissions inventory to prepare a listing of potential control measures, and costs, applied to non-EGU emissions units in the projected 2023 emissions inventory. Using this data, we plotted curves for Tier 1 industries, Tier 2 industries, Tier 1 and 2 industries, and all industries at $500 per ton increments. Figure 1 indicates there is a "knee in the curve" at approximately $7,500 per ton.[12] We used this marginal cost threshold to further assess estimated emissions reductions, air quality improvements, and costs from the potentially impactful industries. Note that controls and related emissions reductions are available at several estimated cost levels up to the $7,500 per ton threshold. The costs do not include monitoring, recordkeeping, reporting, or testing costs.

Figure 1. Ozone Season NOx Reductions and Costs per Ton (CPT) for Tier 1, Tier 2 Industries, and Other Industries



[10] Further information on CoST can be found at the following link: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-analysis-modelstools-air-pollution.

[11] The CMDB is available at the following link: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-analysis-modelstools-air-pollution.

[12] The CoST run results, the CMDB, and the R code that generated the curves are available upon request.

Step 2b - Assessing Non-EGU Emission Reduction Potential and Estimated Air Quality Impacts in Potentially Impactful Industries in 2023

Next, using the marginal cost threshold of $7,500 per ton, to estimate emissions reductions and costs the EPA processed the CoST run using the maximum emission reduction algorithm[13,14] with known controls.[15] We identified controls for non-EGU emissions units in the Tier 1 and Tier 2 industries that cost up to $7,500 per ton. Note that $7,500 per ton represents a marginal cost, and controls and related emissions reductions are available at several estimated costs up to the $7,500 per ton threshold. The costs do not include monitoring, recordkeeping, reporting, or testing costs.

We then calculated air quality impacts associated with the estimated reductions for the 27 linked states in 2023 following the steps below.

1. We binned the estimated reductions by 4-digit NAICS code into the Tier 1 and Tier 2 industries.
2. We used the 2023 state-receptor specific RCU ppb/ton values and the RCU calibration factors used in the AQAT for control analyses in 2023. We multiplied the estimated non-EGU reductions by the ppb/ton values and by the receptor-specific calibration factor to estimate the ppb impacts from these emissions reductions.[16]

Note that we did not include the impact of reductions in the "home state" even if the "home state" was linked to receptor(s) in another state. That is, we only looked at the impact of NOx emissions reductions from upwind states. Furthermore, for each receptor we included impacts from states that are upwind to any receptor, not just those states that are upwind to that particular receptor.

Step 2c – Refining Tier 2 by Identifying Potentially Impactful Boilers in 2023

In 2023 because boilers represent the majority emissions unit in the Tier 2 industries for which there were controls that cost up to $7,500 per ton (see Table 1 below), we targeted emissions reductions and air quality improvements in Tier 2 industries by identifying potentially impactful industrial, commercial, and institutional (ICI) boilers.

[13] The maximum emission reduction algorithm assigns to each source the single measure (if a measure is available for the source) that provides the maximum reduction to the target pollutant. For more information, see the CoST User's Guide available at the following link: https://www.cmascenter.org/cost/documentation/3.7/CoST%20User's%20Guide/.
[14] The maximum emission reduction CoST run results and CMDB are available upon request.
[15] *Known controls* are well-demonstrated control devices and methods that are currently used in practice in many industries. *Known controls* do not include cutting edge or emerging pollution control technologies.
[16] The 2023 state-receptor specific RCU ppb/ton values, the RCU calibration factors used in AQAT for control analyses in 2023, the R code that processed the CoST run results using the maximum emission reduction algorithm, and the summaries of the air quality improvements are available upon request.

Table 1. Number of Emissions Unit Types in Tier 2 Industries

	Number of Emissions Units by Type		
Tier 2 Industries	**Boiler**	**Internal Combustion Engine**	**Industrial Processes**
Metal Ore Mining	--	1	15
Pulp, Paper, and Paperboard Mills	49	1	--
Petroleum and Coal Products Manufacturing	37	4	48
Basic Chemical Manufacturing	46	8	13
Lime and Gypsum Product Manufacturing	--	--	1
Totals	**132**	**14**	**77**

To identify potentially impactful boilers, using the projected 2023 emissions inventory in the linked upwind states we identified a universe of boilers with >100 tpy NOx emissions that had any contributions at downwind receptors.[17,18] We refined the universe of boilers to a subset of impactful boilers by sequentially applying the three criteria below to each boiler. This approach is similar to the overall analytical framework and was tailored for application to individual boilers.[19,20]

- Criterion 1 -- Estimated maximum air quality contribution at an individual receptor of >=0.0025 ppb ***or*** estimated total contribution across downwind receptors of >=0.01 ppb***.***
- Criterion 2 -- Controls that cost up to $7,500 per ton.
- Criterion 3 -- Estimated maximum air quality improvement at an individual receptor of >=0.001 ppb.

IV. Modifying the Analytical Framework for the Screening Assessment for 2026

EPA concluded, based on the most recent information available from the CSAPR Update Non-EGU TSD, that controls on all of the non-EGU emissions units cannot be installed by the 2023 ozone season. As such, we prepared a screening assessment for the year 2026 by generally applying the analytical framework detailed above. Specifically, we

- Retained the impactful industries identified in Tier 1 and Tier 2, the $7,500 cost per ton threshold, and the methodology for identifying impactful boilers,
- Modified the framework to address challenges associated with using the projected 2023 emissions inventory by using the 2019 emissions inventory, and
- Updated the air quality modeling data by using data for 2026.

Using the projected 2023 emissions inventory introduced challenges associated with the application of new source performance standards (NSPS).[21] Some of the projected emissions inventory records reflected percent

[17] We used the 2023fj non-EGU point source inventory files from the 2016v2 emissions platform.
[18] MD, MO, NV, and WY did not have boilers with >100 tpy NOx emissions.
[19] For the impactful boiler assessment, the estimated air quality contributions and improvements were not based on modeling of individual emissions units or emissions source sectors. The air quality estimates were derived by using the 2023 state/receptor specific RCU ppb/ton values and the RCU calibration factors used in AQAT. The results are intended to provide a general indication of the relative impact across sources.
[20] For the impactful boiler assessment, the 2023 state-receptor specific RCU ppb/ton values, the RCU calibration factors used in the AQAT for ozone for control analyses in 2023, and the R code that processed the CoST run results are available upon request.
[21] Using the projected inventory also introduced challenges associated with the growth of emissions at sources over time. EPA determined that the 2019 inventory was appropriate because it provided a more accurate prediction of potential near-

reductions associated with the application of current NSPS (e.g., Reciprocating Internal Combustion Engine, Natural Gas Turbines, Process Heaters NSPS). Applying NSPSs during the emissions projections process includes estimating the number of modifications/replacements that would trigger NSPS requirements. None of the existing sources, as they currently exist, would install a control because of a NSPS. But some of those sources might modify and become subject to the NSPS. Because we do not know which sources might become subject to an NSPS by modifying, across-the-board percent reductions from unknown control measures are applied to all of the sources.[22] As a result, CoST replaced some of the unknown control measures with a control measure that it concluded was more efficient. However, we do not know if a control would be applied to a particular source in response to the NSPS rules and if so, what that control would be. Therefore, we do not know if CoST is correctly replacing those unknown control measures. To address this challenge, we used a current, not projected, emissions inventory along with the latest air quality modeling information for 2026. Specifically, we used the 2019 inventory for information on emissions, emissions units, and estimated emissions reductions in concert with the emissions sector-specific (non-EGU-specific) ppb/ton factors for 2026 and 2026 AQAT calibration factors to estimate the impacts on future air quality from reductions at emissions units as those units currently exist.[23]

V. Screening Assessment Results for 2026 -- Estimated Total Emissions Reductions, Air Quality Improvements, and Annual Total Costs for Emissions Units in Tier 1 Industries and Impactful Boilers in Tier 2 Industries

This screening assessment is not intended to be, nor take the place of, a unit-specific detailed engineering analysis that fully evaluates the feasibility of retrofits for the emissions units, potential controls, and related costs. We used CoST to identify emissions units, emissions reductions, and costs to include in a proposed FIP; however, CoST was designed to be used for illustrative control strategy analyses (e.g., NAAQS regulatory impact analyses) and not for unit-specific, detailed engineering analyses. The estimates from CoST identify proxies for (1) non-EGU emissions units that have emission reduction potential, (2) potential controls for and emissions reductions from these emissions units, and (3) control costs from the potential controls on these emissions units.

See Sections VII.A.2. and VII.C. of the proposal preamble for discussions of the NOx emissions limits, compliance timing, and other related rule requirements for the industries and emissions unit types identified through this screening assessment.

To prepare the screening assessment for 2026, we applied the analytical framework detailed in the sections above with the modifications discussed in the previous section. The assessment includes emissions units from the Tier 1 industries and impactful boilers from the Tier 2 industries. Using the latest air quality modeling for 2026, we identified upwind states linked to downwind nonattainment or maintenance receptors using the 1% of the NAAQS threshold criterion, or 0.7 ppb. In 2026 there are 23 linked states for the 2015 NAAQS: AR, CA, IL, IN, KY, LA, MD, MI, MN, MO, MS, NJ, NY, NV, OH, OK, PA, TX, UT, VA, WI, WV, and WY.
We re-ran CoST with known controls, the CMDB, and the 2019 emissions inventory. We specified CoST to allow replacing an existing control if a replacement control is estimated to be >10 percent more effective than the

term emissions reductions. For additional discussion of the 2019 inventory, please see the *2019 National Emissions Inventory Technical Support Document: Point Data Category* available in the docket. In switching to the 2019 inventory, however, we did not account for any growth or decrease in emissions that might occur at individual units. Because the controls applied by CoST have efficiencies, or percent reductions, this means we could be over- or under-estimating the emission reductions and their ppb impacts.

[22] For additional information on the 2016v2 inventory and the projected 2023 emissions inventory, please see the September 2021 *Technical Support Document Preparation of Emissions Inventories for 2016v2 North American Emissions Modeling Platform* in the docket or available at the following link: https://www.epa.gov/system/files/documents/2021-09/2016v2_emismod_tsd_september2021.pdf.

[23] For this proposed FIP, the EPA used the ozone AQAT, which is described in detail in *Ozone Policy Analysis Proposed Rule TSD* in the docket. The receptor-state specific calibration factors for 2026 were derived using the following air quality modeling runs: 2026 base case and 2026 control case with 30 percent across-the-board NOx emissions cuts.

existing control. We did not replace an existing control if the 2019 emissions inventory indicated the presence of that control, even if the CMDB reflects a greater control efficiency for that control. Also, we removed six facilities from consideration because they are subject to an existing consent decree, are shut down, or will shut down by 2026. See Appendix B for a summary of the facilities removed.

For the emissions units in the Tier 1 industries and the impactful boilers in the Tier 2 industries, the estimated emissions reductions, air quality improvements, and costs are summarized below and in Tables 2 through 5 that follow. The cost estimates do not include monitoring, recordkeeping, reporting, or testing costs.[24] As shown in Table 2, the total estimated ozone season emissions reductions are 47,186 tons, the estimated total ppb improvement across all downwind receptors is 5.16 ppb, and the estimated total cost is $410.8 million annually. The estimated ozone season reductions, total ppb improvements, and total cost are representative of single year impacts and not cumulative impacts.

Table 3 presents estimated ppb improvements at receptors grouped by region. For the coastal Connecticut/New York City nonattainment area receptors, total ppb improvements from Tier 1 and Tier 2 range from 0.247 to 0.356 ppb; for the receptors near Chicago, total ppb improvements range from 0.261 to 0.375 ppb; for the receptors along the western shoreline of Lake Michigan in Wisconsin, total ppb improvements range from 0.360 to 0.443 ppb; for the Houston receptors, total ppb improvements range from 0.284 to 0.472 ppb; and for the western receptors, ppb improvements range from <0.001 to 0.056 ppb. There are far fewer emissions reductions from western states because there are far fewer states and impacted emissions units in the west, and the resulting air quality improvements are noticeably lower.

For Tier 1 industries and the impactful boilers in the Tier 2 industries, Table 4 provides by state and by industry estimated emissions reductions and costs; Table 4a provides by state, estimated emissions reductions and costs. New Jersey and Nevada are not included in these tables because they did not have any estimated non-EGU reductions from the Tier 1 industries and boilers in Tier 2 industries that cost up to $7,500 per ton. In addition, Figure 2 shows the geographical distribution of ozone season reductions.

Table 5 provides by industry and east/west, the number and type of emissions units, total estimated emissions reductions, total ppb improvements, and costs. There are 489 emissions units contributing to the total estimated reductions of 47,186 ozone season tons and total estimated ppb improvements of 5.16 ppb.[25]

Table 6 includes by industry, the emissions source group, control technology, number of emissions units, ozone season emissions reductions, and annual total cost for the emissions units in the screening assessment. Lastly, Tables 7, 8, and 9 provide summaries of estimated ozone season emissions reductions, annual total cost, and average cost per ton by the control technologies CoST applied (i) across all non-EGU emissions units, (ii) across non-EGU emissions units grouped by the Tier 1 industries and impactful boilers in Tier 2 industries, and (iii) across non-EGU emissions units grouped by the seven individual Tier 1 and 2 industries.

[24] EPA submitted an information collection request (ICR) to OMB associated with the proposed monitoring, calibrating, recordkeeping, reporting and testing activities required for non-EGU emissions units -- *ICR for the Proposed Rule, Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Primary Ozone National Ambient Air Quality Standard: Transport Obligations for non-Electric Generating Units*, EPA ICR No. 2705.01. The ICR is summarized in Section XI.B.2 of the proposed rule preamble. The ICR includes estimated monitoring, recordkeeping, reporting, and testing costs of approximately $11.45 million per year for the first three years. These costs are not reflected in the cost estimates presented in Tables 2 through 9.

[25] While the number of units listed in Table 5 sums to 491, the emissions inventory records for two of the units in Tier 1 industries include SCCs for both boilers and industrial processes. As a result, those units appear twice in the counts.

For the Excel workbooks with Tables 2 through 9, see *Transport Proposal – NonEGU Results – 03-16-2022.xlsx* and *Non-EGU Analysis Controls – 11-15-2021.xlsx* in the docket.[26]

[26] The R code that processed the CoST run results, the sector-specific (non-EGU-specific) ppb/ton values, and the 2026 AQAT calibration factors used to prepare these tables are available upon request.

All costs are in 2016$ and do not include monitoring, recordkeeping, reporting, or testing costs.

Table 2. Estimated Emissions Reductions (ozone season tons), Maximum PPB Improvements, and Costs

Option	Ozone Season Emissions Reductions (East/West)	Total PPB Improvement Across All Downwind Receptors	Max PPB Improvement Across All Downwind Receptors	Annual Total Cost (million $) (Avg Annual Cost per Ton)	Industries (# of emissions units > 100 tpy in identified industries)
Tier 1 Industries with Known Controls that Cost up to $7,500/ton	41,153 (37,972/3,181)	4.352	0.392	$356.6 ($3,610)	Cement and Concrete Product Manufacturing (47), Glass and Glass Product Manufacturing (44), Iron and Steel Mills and Ferroalloy Manufacturing (39), Pipeline Transportation of Natural Gas (307)
Tier 2 Industry Boilers with Known Controls that Cost up to $7,500/ton	6,033 (5,965/68)	0.809	0.169	$54.2 ($3,744)	Basic Chemical Manufacturing (17), Petroleum and Coal Products Manufacturing (10), Pulp, Paper, and Paperboard Mills (25)

The estimated ozone season reductions, total ppb improvements, and total cost are representative of single year impacts and not cumulative impacts.

*Ozone season tons are calculated as tpy from the NEI multiplied by 5/12.

Note that New Jersey and Nevada did not have any estimated non-EGU reductions that cost up to $7,500 per ton from the Tier 1 industries and boilers in Tier 2 industries.

Table 4a. For Tier 1 Industries and Impactful Boilers in Tier 2 Industries, By State, Estimated Emissions Reductions (ozone season tons) and Costs

	Tier 1		Tier 2	
State	Ozone Season Emissions Reductions	Annual Total Cost (million $) (Avg Annual Cost per Ton)	Ozone Season Emissions Reductions	Annual Total Cost (million $) (Avg Annual Cost per Ton)
AR	922	$10.4 ($4,679)	732	$7.2 ($4,102)

Blue highlights reflect western states information.
Orange highlights reflect Tier 2 industries with impactful boilers.

Table 6. By Industry, Emissions Source Group, Control Technology, Number of Units, Estimated Emissions Reductions (ozone season tons), and Annual Total Cost

Industry	Emissions Source Group	Control Technology	Number of Units	Ozone Season Emissions Reductions	Annual Total Cost (million $)
Cement and Concrete Product Manufacturing	Boilers - < 10 Million BTU/hr; Industrial Processes - Kiln	Ultra Low NOx Burner; Selective Non-Catalytic Reduction	1	117	$0.5
	Industrial Processes - Kiln	Selective Non-Catalytic Reduction	24	3,123	$9.7
	Industrial Processes - Preheater Kiln	Selective Non-Catalytic Reduction	3	342	$1.2
	Industrial Processes - Preheater/Precalciner Kiln	Selective Non-Catalytic Reduction	19	4,510	$17.5
Glass and Glass Product Manufacturing	Industrial Processes - Container Glass: Melting Furnace	Selective Catalytic Reduction	27	1,676	$8.7
	Industrial Processes - Flat Glass: Melting Furnace	Selective Catalytic Reduction	13	4,674	$12.7
	Industrial Processes - Furnace: General	Oxygen Enriched Air Staging	1	52	$0.1
	Industrial Processes - Pressed and Blown Glass: Melting Furnace	Selective Catalytic Reduction	3	264	$2.7
Iron and Steel Mills and Ferroalloy Manufacturing	Boilers - > 100 Million BTU/hr	Ultra Low NOx Burner and Selective Catalytic Reduction	3	383	$4.2
	Boilers - > 100 Million BTU/hr	Ultra Low NOx Burner	6	282	$2.2
	Boilers - > 100 Million BTU/hr	Selective Catalytic Reduction	2	106	$1.2
	Boilers - > 100 Million BTU/hr; Boilers - Blast Furnace Gas	Ultra Low NOx Burner	1	166	$1.0
	Boilers - > 100 Million BTU/hr; Boilers - Coke Oven Gas	Ultra Low NOx Burner	6	360	$2.9
	Boilers - > 100 Million BTU/hr; Boilers - Coke Oven Gas	Selective Catalytic Reduction; Ultra Low NOx Burner and Selective Catalytic Reduction	1	114	$1.7
	Boilers - Blast Furnace Gas	Ultra Low NOx Burner	1	65	$0.4
	Boilers - Blast Furnace Gas; Industrial Processes - Sintering: Windbox; Industrial Processes - Blast Furnace: Casting/Tapping: Local Evacuation; Industrial Processes - Process Gas: Process Heaters	Ultra Low NOx Burner; Selective Catalytic Reduction; Low NOx Burner and Flue Gas Recirculation	1	440	$4.4
	Boilers - Coke Oven Gas	Ultra Low NOx Burner and Selective Catalytic Reduction	3	394	$3.7
	Boilers - Coke Oven Gas; Boilers - > 100 Million BTU/hr	Ultra Low NOx Burner; Ultra Low NOx Burner and Selective Catalytic Reduction	1	116	$1.6
	Industrial Processes - Basic Oxygen Furnace (BOF): Open Hood Stack	Selective Catalytic Reduction	2	185	$1.9
	Industrial Processes - Basic Oxygen Furnace (BOF): Open Hood Stack; Industrial Processes - General	Selective Catalytic Reduction; Low NOx Burner	1	172	$1.7
	Industrial Processes - Basic Oxygen Furnace (BOF): Top Blown Furnace: Primary	Selective Catalytic Reduction	1	50	$0.5
	Industrial Processes - Blast Furnace: Casting/Tapping: Local Evacuation	Selective Catalytic Reduction	1	38	$0.4
	Industrial Processes - General	Low NOx Burner	5	191	$1.7
	Industrial Processes - General; Industrial Processes - Coke Oven or Blast Furnace	Low NOx Burner; Low NOx Burner and Flue Gas Recirculation	1	84	$1.0
	Industrial Processes - Other Not Classified	Low NOx Burner and Flue Gas Recirculation	2	43	$0.1
	Industrial Processes - Sintering: Windbox	Selective Catalytic Reduction	1	60	$0.6
Pipeline Transportation of Natural Gas	Internal Combustion Engines - 2-cycle Clean Burn	Layered Combustion	1	60	$0.8
	Internal Combustion Engines - 2-cycle Lean Burn	Layered Combustion	136	12,645	$165.6
	Internal Combustion Engines - 4-cycle Lean Burn	Selective Catalytic Reduction	41	2,656	$21.6
	Internal Combustion Engines - 4-cycle Rich Burn	Non-Selective Catalytic Reduction	2	147	$0.2
	Internal Combustion Engines - Reciprocating	Non-Selective Catalytic Reduction or Layered Combustion	94	6,329	$72.0
	Internal Combustion Engines - Reciprocating	Adjust Air to Fuel Ratio and Ignition Retard	12	193	$1.1
	Internal Combustion Engines - Reciprocating	Non-Selective Catalytic Reduction or Layered Combustion; Adjust Air to Fuel Ratio and Ignition Retard	1	49	$0.4
	Internal Combustion Engines - Turbine	Selective Catalytic Reduction and Steam Injection	17	929	$8.4
	Internal Combustion Engines - Turbine	SCR + DLN Combustion	3	136	$2.1

Basic Chemical Manufacturing	Boilers - > 100 Million BTU/hr	Ultra Low NOx Burner and Selective Catalytic Reduction	6	786	$7.5
	Boilers - > 100 Million BTU/hr	Selective Catalytic Reduction	2	104	$1.5
	Boilers - 10-100 Million BTU/hr	Ultra Low NOx Burner and Selective Catalytic Reduction	1	133	$1.0
	Boilers - 10-100 Million BTU/hr	Selective Catalytic Reduction	1	43	$0.1
	Boilers - Cogeneration	Selective Catalytic Reduction	1	68	$0.9
	Boilers - Distillate Oil - Grades 1 and 2: Boiler	Selective Catalytic Reduction	1	47	$0.6
	Boilers - Petroleum Refinery Gas	Ultra Low NOx Burner and Selective Catalytic Reduction	2	293	$2.8
	Boilers - Petroleum Refinery Gas	Ultra Low NOx Burner	2	138	$0.8
	Boilers - Subbituminous Coal: Traveling Grate (Overfeed) Stoker	Selective Catalytic Reduction	1	87	$1.1
Petroleum and Coal Products Manufacturing	Boilers - > 100 Million BTU/hr	Ultra Low NOx Burner	1	41	$0.2
	Boilers - > 100 Million BTU/hr; Boilers - Blast Furnace Gas	Ultra Low NOx Burner	1	38	$0.4
	Boilers - Boiler, >= 100 Million BTU/hr	Natural Gas Reburn	1	284	$1.8
	Boilers - Coke Oven Gas	Ultra Low NOx Burner	1	98	$0.6
	Boilers - Petroleum Refinery Gas	Ultra Low NOx Burner and Selective Catalytic Reduction	3	433	$3.8
	Boilers - Petroleum Refinery Gas	Ultra Low NOx Burner	3	137	$0.9
Pulp, Paper, and Paperboard Mills	Boilers - > 100 Million BTU/hr	Ultra Low NOx Burner and Selective Catalytic Reduction	5	618	$6.8
	Boilers - > 100 Million BTU/hr	Ultra Low NOx Burner	3	151	$1.0
	Boilers - > 100 Million BTU/hr	Selective Catalytic Reduction	1	68	$1.2
	Boilers - 10-100 Million BTU/hr	Ultra Low NOx Burner	2	106	$0.5
	Boilers - Bituminous Coal: Cyclone Furnace	Selective Catalytic Reduction	2	662	$3.4
	Boilers - Bituminous Coal: Pulverized Coal: Dry Bottom	Ultra Low NOx Burner and Selective Catalytic Reduction	1	111	$1.1
	Boilers - Bituminous Coal: Pulverized Coal: Dry Bottom; Boilers - > 100 Million BTU/hr	Low NOx Burner; Selective Catalytic Reduction	1	98	$1.4
	Boilers - Bituminous Coal: Spreader Stoker	Selective Catalytic Reduction	3	251	$3.2
	Boilers - Cogeneration	Ultra Low NOx Burner and Selective Catalytic Reduction	2	338	$2.9
	Boilers - Fluid Catalytic Cracking Unit with CO Boiler: Natural Gas	Ultra Low NOx Burner and Selective Catalytic Reduction	2	289	$2.7
	Boilers - Subbituminous Coal: Boiler, Spreader Stoker	Selective Catalytic Reduction	2	348	$3.7
	Boilers - Subbituminous Coal: Spreader Stoker	Selective Catalytic Reduction	1	266	$2.3

Table 7. Estimated Emissions Reductions (ozone season tons), Annual Total Cost, and Average Cost per Ton by Control Technology Across All Non-EGU Emissions Units

Control Technology	OS NOx Reductions	Annual Total Cost	Average Cost per Ton
Adjust Air to Fuel Ratio and Ignition Retard	212	$1,216,435	$2,393
Layered Combustion	12,706	$166,398,282	$5,457
Low NOx Burner	231	$2,092,579	$3,773
Low NOx Burner and Flue Gas Recirculation	200	$2,054,876	$4,288
Natural Gas Reburn	284	$1,843,948	$2,703
Non-Selective Catalytic Reduction	147	$205,808	$585
Non-Selective Catalytic Reduction or Layered Combustion	6,359	$72,383,222	$4,743
Oxygen Enriched Air Staging	52	$95,641	$764
SCR + DLN Combustion	136	$2,060,943	$6,301
Selective Catalytic Reduction	12,239	$74,692,132	$2,543
Selective Catalytic Reduction and Steam Injection	929	$8,439,921	$3,787
Selective Non-Catalytic Reduction	8,076	$28,782,335	$1,485
Ultra Low NOx Burner	1,670	$11,584,405	$2,890
Ultra Low NOx Burner and Selective Catalytic Reduction	3,946	$38,959,490	$4,114

Table 8. Estimated Emissions Reductions (ozone season tons), Annual Total Cost, and Average Cost per Ton by Control Technology Across Non-EGU Emissions Units Grouped by the Tier 1 Industries and Impactful Boilers in Tier 2 Industries

Tier	Control Technology	OS NOx Reductions	Annual Total Cost	Average Cost per Ton
Tier 1	Adjust Air to Fuel Ratio and Ignition Retard	212	$1,216,435	$2,393
Tier 1	Layered Combustion	12,706	$166,398,282	$5,457
Tier 1	Low NOx Burner	211	$1,852,495	$3,656
Tier 1	Low NOx Burner and Flue Gas Recirculation	200	$2,054,876	$4,288
Tier 1	Non-Selective Catalytic Reduction	147	$205,808	$585
Tier 1	Non-Selective Catalytic Reduction or Layered Combustion	6,359	$72,383,222	$4,743
Tier 1	Oxygen Enriched Air Staging	52	$95,641	$764
Tier 1	SCR + DLN Combustion	136	$2,060,943	$6,301
Tier 1	Selective Catalytic Reduction	10,219	$55,575,188	$2,266
Tier 1	Selective Catalytic Reduction and Steam Injection	929	$8,439,921	$3,787
Tier 1	Selective Non-Catalytic Reduction	8,076	$28,782,335	$1,485
Tier 1	Ultra Low NOx Burner	962	$7,172,778	$3,107
Tier 1	Ultra Low NOx Burner and Selective Catalytic Reduction	946	$10,362,549	$4,567
Tier 2	Low NOx Burner	20	$240,084	$5,022
Tier 2	Natural Gas Reburn	284	$1,843,948	$2,703
Tier 2	Selective Catalytic Reduction	2,020	$19,116,944	$3,942
Tier 2	Ultra Low NOx Burner	708	$4,411,626	$2,594
Tier 2	Ultra Low NOx Burner and Selective Catalytic Reduction	3,000	$28,596,941	$3,972

Table 9. Estimated Emissions Reductions (ozone season tons), Annual Total Cost, and Average Cost per Ton by Control Technology Across Non-EGU Emissions Units Grouped by the Seven Individual Tier 1 and Tier 2 Industries

Industry	Control Technology	OS NOx Reductions	Annual Total Cost	Average Cost per Ton
Cement and Concrete Product Manufacturing	Selective Non-Catalytic Reduction	8,076	$28,782,335	$1,485
Cement and Concrete Product Manufacturing	Ultra Low NOx Burner	16	$169,531	$4,410
Glass and Glass Product Manufacturing	Oxygen Enriched Air Staging	52	$95,641	$764
Glass and Glass Product Manufacturing	Selective Catalytic Reduction	6,615	$24,062,362	$1,516
Iron and Steel Mills and Ferroalloy Manufacturing	Low NOx Burner	211	$1,852,495	$3,656
Iron and Steel Mills and Ferroalloy Manufacturing	Low NOx Burner and Flue Gas Recirculation	200	$2,054,876	$4,288
Iron and Steel Mills and Ferroalloy Manufacturing	Selective Catalytic Reduction	948	$9,886,092	$4,345
Iron and Steel Mills and Ferroalloy Manufacturing	Ultra Low NOx Burner	946	$7,003,247	$3,085
Iron and Steel Mills and Ferroalloy Manufacturing	Ultra Low NOx Burner and Selective Catalytic Reduction	946	$10,362,549	$4,567
Pipeline Transportation of Natural Gas	Adjust Air to Fuel Ratio and Ignition Retard	212	$1,216,435	$2,393
Pipeline Transportation of Natural Gas	Layered Combustion	12,706	$166,398,282	$5,457
Pipeline Transportation of Natural Gas	Non-Selective Catalytic Reduction	147	$205,808	$585
Pipeline Transportation of Natural Gas	Non-Selective Catalytic Reduction or Layered Combustion	6,359	$72,383,222	$4,743
Pipeline Transportation of Natural Gas	SCR + DLN Combustion	136	$2,060,943	$6,301
Pipeline Transportation of Natural Gas	Selective Catalytic Reduction	2,656	$21,626,734	$3,393
Pipeline Transportation of Natural Gas	Selective Catalytic Reduction and Steam Injection	929	$8,439,921	$3,787

Pulp, Paper, and Paperboard Mills	Ultra Low NOx Burner and Selective Catalytic Reduction	1,356	$13,507,360	$4,151

VI. Request for Comment and Additional Information

In this screening assessment the EPA used CoST, the CMDB, and the 2019 emissions inventory to assess emission reduction potential from non-EGU emissions units in several industries. We identified emissions units that were uncontrolled or that could be better controlled and then applied control technologies to estimate emissions reductions and costs. As noted above, the cost estimates do not include monitoring, recordkeeping, reporting, or testing costs.

As discussed in Section VI.D.2.a of the proposal preamble, the EPA requests comment on the capital and annual costs of several potential control technologies, and in particular whether ultra-low NO_X burners or low NO_X burners are generally considered part of the process or add-on controls for ICI boilers (and how process changes or retrofits to accommodate controls would affect the cost estimates); the effectiveness of low emissions combustion in controlling NO_X from reciprocating IC engines, compared to other potential NO_X controls for these engines; and whether controls on ICI boilers and reciprocating IC engines are likely to be run all year or only during the ozone season.

The EPA also requests comment on the time needed to install the various control technologies across all of the emissions units in the Tier 1 and Tier 2 industries. In particular, the EPA solicits comment on the time needed to obtain permits, the availability of vendors and materials, and the earliest possible installation times for SCR on glass furnaces; SNCR on cement kilns; ultra-low NO_X burners, low NO_X burners, and SCR on ICI boilers (coal-fired, gas-fired, or oil-fired); low NO_X burners on large non-EGU ICI boilers; and low emissions combustion, layered emissions combustion, NSCR, and SCR on reciprocating rich-burn or lean-burn IC engines.

Finally, with respect to emissions monitoring requirements, the EPA requests comment on the costs of installing and operating CEMS at non-EGU sources without NO_X emissions monitors; the time needed to program and install CEMS at non-EGU sources; whether monitoring techniques other than CEMS, such as predictive emissions monitoring systems (PEMS), may be sufficient for certain non-EGU facilities, and the types of non-EGU facilities for which such PEMS may be sufficient; and the costs of installing and operating monitoring techniques other than CEMS.

APPENDIX A – Analysis of Industry Contribution Data

This appendix describes the analyses performed to help focus the non-EGU analytical framework and resulting screening assessment on the most impactful industries.

To inform this analysis, first using the procedure described in Section III, Step 1 above, we estimated contributions from each of 41 industries to each nonattainment and maintenance receptor in 2023 and used these data to calculate the 5 metrics identified in Table A-1.[27,28] A summary of the data for each metric for each industry is provided in Table A-3. These metrics were selected to provide air quality information to inform an evaluation of the magnitude and geographic scope of contributions from individual industries. Metrics 1, 2, and 3 provide information on the magnitude of the contribution. Metric 4 provides information on the geographic scope of the downwind impact, whereas Metric 5 provides information on the geographic scope of upwind state contributions. Of the three air quality metrics we chose to analyze the data for Metric 2, the maximum contribution to any downwind receptor, because this metric aligns with the air quality metric used in Step 2 of the four-step interstate transport framework to identify linked upwind states for further review in Step 3 of the interstate transport framework. To examine the geographic breadth of the industry contributions we chose Metric 4 because that metric provides information on the extent of impacts on downwind air quality problems.

Table A-1. Contribution Metrics for Non-EGU Assessment

1	Total contribution to all downwind receptors
2	Maximum contribution to any downwind receptor
3	Average contribution across all receptors
4	Number of receptors with contributions >= 0.01 ppb
5	Number of linked upwind states with highest industry contribution >= 0.01 ppb

Next, we evaluated the maximum downwind contributions to identify the most impactful industries for further analysis. This approach included a semi-quantitative examination of rank-ordered maximum contributions to identify breakpoints in the data that might serve as an initial screen to eliminate non-impactful industries from further analysis of the contribution data. The distribution of maximum contributions provided in Table A-3 indicate that there is a large range in the values across the 41 industries. Specifically, 5 industries individually contribute more than 0.10 ppb, 3 industries contribute between 0.05 ppb and 0.10 ppb, 11 industries contribute between 0.01 and 0.05 ppb, 8 industries contribution between 0.005 and 0.01 ppb, and 14 industries contribute less than 0.005 ppb.

The rank-ordered maximum downwind contributions from individual industries are shown in Figure A-1. In this figure each point represents the maximum contribution to a downwind receptor from a particular industry. Note that the values for the highest contributing industries are not show in the figure in order to provide greater resolution of the shape of the distribution at the lower end of the values. The declining curve in Figure A-1 exhibits a shape similar to a harmonic distribution. Initially, there is a fairly steep drop in contributions with a breakpoint between roughly 0.04 and 0.06 ppb followed by a steady decline to 0.01 ppb. Beyond 0.01 ppb the shape of the distribution is much flatter. The data suggest that perhaps 0.05 ppb or 0.01 ppb could serve as breakpoints in the data. Based on the distribution

[27] Receptors in California were not considered in evaluating the impacts of non-EGU sources because EPA's contributions from upwind states to these receptors at Step 2 of the four-step interstate transport framework finds that these monitoring sites are overwhelmingly impacted by in-state emissions to a degree not comparable with any other identified nonattainment or maintenance-only receptors in the country. In this regard, EPA is proposing a determination that California receptors are not sufficiently impacted by interstate transport of ozone to warrant proceeding with a Step 3 evaluation of emissions reduction opportunities.

[28] The methods for identifying receptors are described in the Air Quality Modeling TSD for this proposed rule.

of the data we determined that 0.01 ppb provides a meaningful conservative breakpoint for screening out non-impactful industries from the non-EGU contribution analysis. The specific industries with a maximum downwind contribution >= 0.01 ppb are identified in Table A-2.

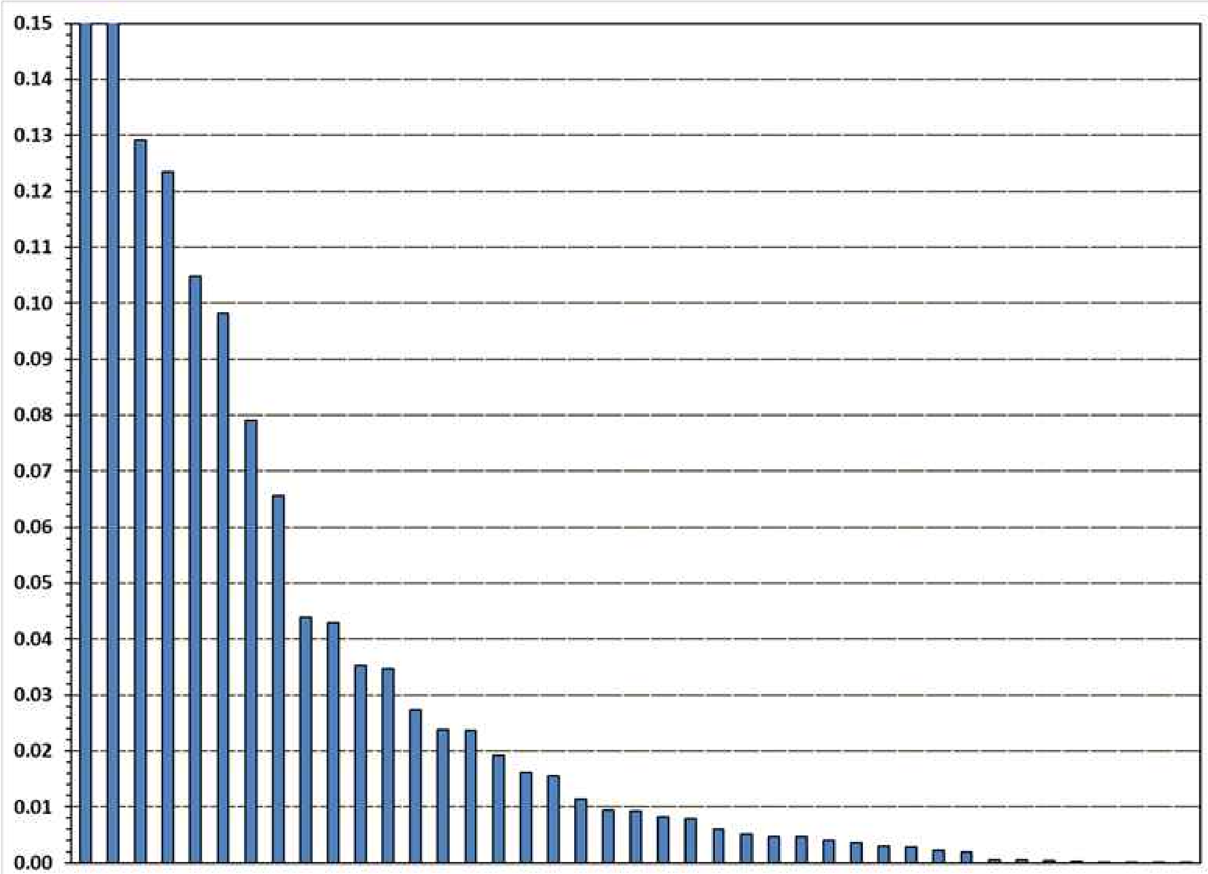

Figure A-1. Rank-ordered maximum downwind contributions from individual industries

We then examined the data for Metrics 2 and 4 for each industry that has a maximum contribution >= 0.01 ppb. The data for Metric 4, as shown in Figure A-2, suggests that there as a breakpoint between those industries that contribute to 10 or more receptors versus those industries that contribute to fewer than 10 receptors. Table A-2 provides the data for Metrics 2 and 4, ranked by the magnitude of Metric 4. The data show that 8 industries contribute >= 0.01 ppb to more than 10 receptors. Of these 8 industries, 5 have a maximum contributions of > 0.10 ppb to one of these receptors. In addition, one industry, Basic Chemical Manufacturing, contributes to only 9 receptors, but the maximum contribution to one of these receptors is >0.10 ppb. Using this information, we grouped the 9 industries into one of 2 tiers based on considering both the magnitude of the contribution and the downwind extent of affected receptors. Tier 1 includes the 4 industries that each have (1) a maximum contribution to any one receptor of >0.10 ppb and (2) a contribution >= 0.01 ppb to at least 10 receptors. Tier 2 includes the 5 industries that each have (1) a maximum contribution to any one receptor >=0.10 ppb but contribute >=0.01 ppb to fewer than 10 receptors, or (2) a maximum contribution <0.10 ppb but contribute >=0.01 ppb to at least 10 receptors.

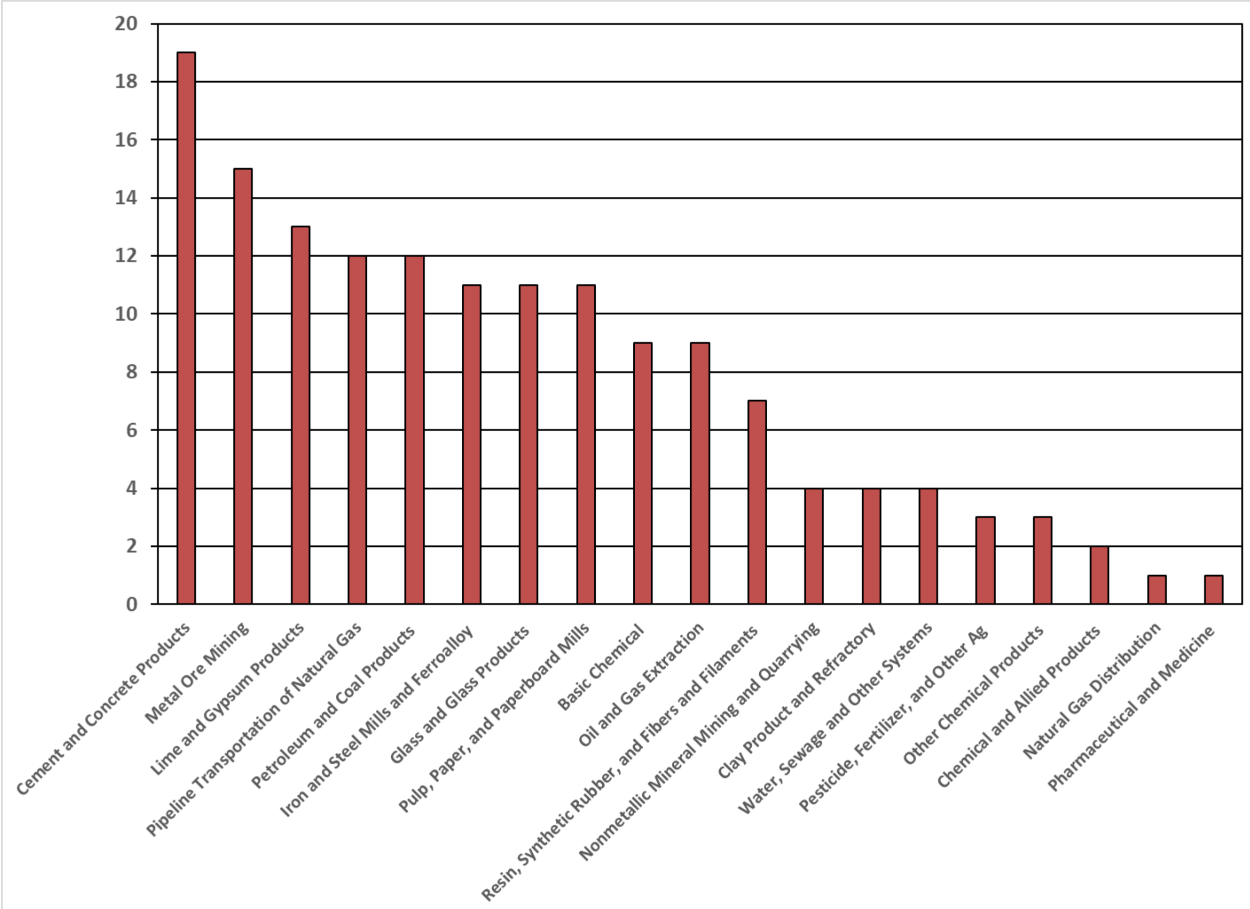

Figure A-2. Number of downwind receptors with contributions >= 0.10 ppb for each industry with a maximum downwind contribution >= 0.01 ppb

1st Tier of Industries for Further Analysis Based on AQ Contributions

These industries (1) have a maximum contribution to any one receptor of >0.10 ppb AND (2) contribute >= 0.01 ppb to at least 10 receptors.

2nd Tier of Industries for Further Analysis Based on AQ Contributions

These industries either have:

(1) a maximum contribution to any one receptor >=0.10 ppb but contribute >=0.01 ppb to fewer than 10 receptors, or

(2) a maximum contribution <0.10 ppb but contribute >=0.01 ppb to at least 10 receptors

Re: Petition for Reconsideration and Stay of the Final Rule: Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, EPA-HQ-OAR-2021-0663; EPA-R05-OAR-2022-0006; 88 Fed. Reg. 9,336 (February 13, 2023)

Dear Administrator Regan:

On behalf of our clients, ALLETE, Inc. d/b/a Minnesota Power; Northern States Power Company – Minnesota d/b/a/ Xcel Energy; Great River Energy; Southern Minnesota Municipal Power Agency; Cleveland-Cliffs, Inc.; and United States Steel Corporation (collectively the "Minnesota Good Neighbor Coalition"), please find enclosed a petition for reconsideration and stay of the disapproval of "prong 2" of Minnesota's State Implementation Plan ("SIP") in the United States Environmental Protection Agency's final rule: Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, EPA-HQ-OAR-2021-0663; EPA-R05-OAR-2022-0006; 88 Fed. Reg. 9,336 (February 13, 2023).

Please contact me with any questions you may have.

Sincerely,

/s/ Douglas A. McWilliams

Before the United States Environmental Protection Agency

In re: Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 Fed. Reg. 9336 (February 13, 2023)	))))))	EPA Docket Nos. EPA–HQ–OAR–2021–0663; EPA–R05–OAR–2022–0006; FRL–10209–01–OAR

Petition for Reconsideration and for Stay of the Air Plan Disapprovals for Interstate Transportation of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards

ALLETE, Inc. d/b/a Minnesota Power; Northern States Power Company – Minnesota d/b/a/ Xcel Energy; Great River Energy; Southern Minnesota Municipal Power Agency; Cleveland-Cliffs, Inc.; and United States Steel Corporation (collectively "Petitioners") respectfully request that the United States Environmental Protection Agency ("EPA") reconsider and stay the portion of its final rule Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 Fed. Reg. 9336 (February 13, 2023) (the "SIP Disapproval") that disapproves Minnesota's state implementation plan ("SIP") for interstate transport for "prong 2" of Clean Air Act ("CAA") § 110(a)(2)(D)(i)(I), 42 U.S.C. § 7410(a)(2)(D)(i)(I).

Minnesota is uniquely situated in the SIP Disapproval. In EPA's February 13 action, Minnesota's SIP was approved for "prong 1"[1] based on EPA's finding that Minnesota does not contribute significantly to nonattainment in any downwind state. Minnesota's SIP was disapproved for "prong 2," with EPA finding that Minnesota was linked to interference with maintenance of a single downwind maintenance-only receptor. EPA has subsequently found in its promulgation of an ozone transport federal implementation plan ("FIP") that Minnesota was not linked to any downwind non-attainment or maintenance-only receptor when modeled for 2026.

Based on the best evidence available in 2018 when Minnesota submitted its SIP to EPA for approval (and on April 1, 2020 when EPA had a statutory obligation to approve or deny the Minnesota SIP), Minnesota was ***<u>not</u>*** linked to interference with attainment or maintenance in any downwind state. But, EPA did not timely act on the Minnesota SIP, and then it moved the goal posts. Based on new modeling and emission data EPA developed years later, (the "2016v2" modeling platform) EPA proposed to find that Minnesota was linked to two downwind maintenance-only receptors due to a modeled impact of less than 1 ppb at each receptor. In the

[1] As discussed on page 4 *infra*, EPA has divided the Good Neighbor obligation set out in Clean Air Act ("CAA") § 110(a)(2)(D), 42 U.S.C. § 7410(a)(2)(D), into two "prongs." The obligation to prohibit sources from emitting air pollutants in an amount which will "contribute significantly to nonattainment" is sometimes referred to as "prong 1," and the obligation to prohibit sources from emitting air pollutants in an amount which will "interfere with maintenance" as "prong 2."

final SIP Disapproval, EPA again revised its emissions data and modeling (the "2016v3" modeling platform) and now finds that Minnesota is linked in 2023 to only a single maintenance-only monitor, at a maximum contribution of 0.85 ppb. Further, EPA has since released updated modeling results for 2026 that show that this same monitor will be in attainment without any material reduction of emissions from Minnesota. As a result, after five years of updates, EPA's modeling results support the same conclusion that Minnesota reached in 2018, namely that additional emissions reductions are not needed to prohibit emissions in Minnesota that will contribute significantly to nonattainment, or interfere with maintenance of, the 2015 8-hour ozone NAAQS in any downwind state. We ask that EPA grant this petition for reconsideration to do what it should have done in 2018—Approve the Minnesota SIP.

The approvability of Minnesota's original SIP submittal is corroborated by two additional pieces of information that were not available during the public comment period for the proposed SIP disapproval or prior to EPA's release of its 2016v3 modeling in 2023. First, EPA's 2016v3 emissions inventory materially overstates Minnesota's 2023 NOx emissions; for example, it incorrectly assumes over 2,800 tons of NOx from an electric generating facility that has been idled since 2019 and is projected to have zero emissions in 2023. By merely correcting the projected actual NOx emissions, Minnesota has already achieved more NOx reductions than EPA's FIP would require of Minnesota. This effectively confirms Minnesota's step 3[2] conclusion in its 2018 SIP that no additional permanent or enforceable measures were needed beyond those already implemented by the state.[3]

Second, as EPA has recognized, its CAMx modeling is subject to significant bias in areas of complex meteorology, including the water/land interface occurring at the sole maintenance monitor that EPA has linked to Minnesota emissions. While EPA released with the final SIP Disapproval a review of this localized bias risk for southern Lake Michigan, that review was materially flawed and does not address the significant over-prediction bias occurring on the precise days EPA selected for use in evaluating Minnesota's SIP. As a result, EPA's general conclusion that adjusting for bias will not affect the outcome of its SIP reviews, does not apply to its review of the Minnesota SIP. To the contrary, adjusting for material bias results in the sole maintenance-only monitor to which Minnesota was linked by EPA becoming an attainment monitor in 2023. In other words, eliminating high-bias days alone completely addresses EPA's objection to Minnesota's 2018 SIP and eliminates Minnesota at Step 1 of EPA's four-step analysis.

Reconsideration is appropriate to make the above corrections to the emissions inventory and to account for modeling bias. After incorporating this new material information into the SIP analysis, we believe that EPA will conclude as we have that Minnesota's original 2018 SIP determination that it is not having a downwind impact on attainment or maintenance that requires additional permanent and enforceable measures was correct and warrants approval of

---

[2] *See* page 4 *infra* for the list of four steps in EPA's 4-step framework for evaluating Good Neighbor SIP submissions.

[3] *See* Minnesota's 110(a)(1) and 110(a)(2) "Infrastructure" State Implementation Plan requirements for the National Ambient Air Quality Standards for Ozone, Promulgated in 2015, EPA-R05-OAR-2022-0006-0005, at 12 (October 1, 2018) ("2018 SIP").

the Minnesota SIP. Reconsideration is also appropriate to address a significant procedural flaw in the finalization of the SIP Disapproval. Specifically, the SIP Disapproval relies on information that was not available to EPA, Minnesota, or any other interested parties until 2023, well past the period for Minnesota's SIP submission and EPA's statutory deadline to approve Minnesota's SIP. While EPA has an obligation to use the best available evidence in making its regulatory decisions, that obligation is not unbounded and cannot be used to circumvent the procedures set forth in the Clean Air Act. When Minnesota timely submitted a SIP that is approvable based on the information known at the time, EPA had an obligation to approve the SIP. The Act does not allow EPA unfettered discretion to delay approval until new information becomes available, and then move the goalposts. For States that have done their part to invest resources in developing a timely and approvable SIP, EPA has a statutory obligation to act. EPA may still consider new scientific data and modeling after the statutory deadline, but there is a separate administrative process available to EPA that respects the State's SIP process. Minnesota should have an approved SIP and EPA should be considering whether new information is sufficiently material to require a "SIP call" pursuant to CAA § 110(k)(5), 42 U.S.C. § 7410(k)(5), to give Minnesota the opportunity to revise its SIP given the new available information. Having chosen to use this new information to disapprove prong 2 of Minnesota's SIP instead, EPA deprived Petitioners, the State, and other interested parties of significant procedural protections and opportunities for public input that were required by the Clean Air Act. Granting reconsideration allows EPA the opportunity to cure the procedural flaw that its final action is based on material information that has not been subject to the notice and comment process.

Given that new information was made available after the close of the public comment period, but before the time for judicial review, that such information actually undermines EPA's basis for disapproving prong 2 of Minnesota's 2018 SIP in the SIP Disapproval, and reconsideration would address the harms caused by significant procedural defects in the SIP Disapproval, Petitioners respectfully request that EPA grant reconsideration for the purpose of reviewing this new information and approving prong 2 of Minnesota's 2018 SIP.

Further, since the disapproval of prong 2 of Minnesota's SIP, and the continued implementation of EPA's subsequently-issued FIP, will cause irreparable harm to Petitioners, we request that EPA grant a stay of the disapproval of prong 2 of Minnesota's SIP pending reconsideration and pending judicial review, which will also address the irreparable harm caused by EPA's FIP.

I. Background

On October 1, 2015, EPA promulgated a revised primary and secondary 8-hour ozone NAAQS of 70 ppb. This created a requirement under the CAA for states to submit revised SIPs to EPA by October 1, 2018.[4] SIPs were required to meet the applicable requirements of CAA § 110(a)(2), 42 U.S.C. § 7410(a)(2), including an obligation, sometimes referred to as a "Good Neighbor" obligation, that the SIPs:

[4] 42 U.S.C. § 7410(a)(1).

> (D) Contain adequate provisions—
>
> > (i) prohibiting, consistent with the provisions of this subchapter, any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will—
> >
> > > (I) contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any such national primary or secondary ambient air quality standard, …

42 U.S.C. § 7410(a)(2)(D). The obligation to prohibit sources from emitting air pollutants in an amount which will "contribute significantly to nonattainment" is sometimes referred to as "prong 1," and the obligation to prohibit sources from emitting air pollutants in an amount which will "interfere with maintenance" as "prong 2," of the Good Neighbor obligation.

While EPA has never promulgated regulations imposing more specific interstate transport requirements than what is contained in the statutory text, EPA has developed a 4-step framework that it stated the agency would use to evaluate a state's compliance with its Good Neighbor obligation. Namely:

(1) Identify monitoring sites that are projected to have problems attaining and/or maintaining the NAAQS (i.e., nonattainment and/or maintenance receptors);

(2) identify states that impact those air quality problems in other (i.e., downwind) states sufficiently such that the states are considered ''linked'' and therefore warrant further review and analysis;

(3) identify the emissions reductions necessary (if any), applying a multifactor analysis, to eliminate each linked upwind state's significant contribution to nonattainment or interference with maintenance of the NAAQS at the locations identified in Step 1; and

(4) adopt permanent and enforceable measures needed to achieve those emissions reductions.[5]

Minnesota took a notably conservative approach in its SIP. First, in EPA's Transport Memo, EPA recognized that its four-step framework was not binding, and offered that states "have flexibility to follow this framework or develop alternative frameworks."[6] Despite this flexibility, Minnesota adopted EPA's framework for its SIP.[7] Second, EPA made clear, in the

[7] 2018 SIP at 5.

Transport Memo and in a separate memorandum published later that year, that states did not need to adopt EPA's suggested 1% threshold for determining significant contributions and interference with maintenance at step 2.[8] Here too, Minnesota did not exercise this flexibility, and chose instead to use EPA's preferred approach.[9] Third, EPA guidance offered states flexibility regarding how to determine which downwind monitors should be considered maintenance receptors.[10] Again, Minnesota followed EPA's suggested approach.[11] In other words, while Minnesota was not required to, it followed EPA's own framework and did not rely on additional flexibilities to demonstrate that it had satisfied its Good Neighbor obligations.[12]

Minnesota also used the best information available at the time to determine its Good Neighbor obligations. Specifically, Minnesota used EPA's own modeling and modeling developed by the Lake Michigan Air Directors Consortium ("LADCO") to identify monitoring sites projected to have problems attaining or maintaining the 2015 ozone NAAQS in 2023.[13] It then projected the state's own contributions to those nonattainment and maintenance monitors using both sets of results.[14] Both EPA's and LADCO's modeling showed that Minnesota would contribute less than 1 percent of the NAAQS to all downwind receptors, with a highest receptor contribution from either model of 0.45 ppb.[15] Thus, following EPA's 4-factor framework, and using EPA's own modeling and proposed threshold, Minnesota demonstrated that it was not contributing significantly to, or interfering with maintenance of, the 2015 ozone NAAQS in any downwind state.

This alone would have been sufficient to satisfy Minnesota's Good Neighbor obligation. Minnesota also, however, included in its SIP submission a "step 3" analysis demonstrating that Minnesota emissions of ozone precursors had been reduced from 2002 through 2015 and would be further reduced by emission limitations and reductions required by other programs.[16] Under this step 3 analysis, Minnesota demonstrated that, even if the state were having more than an insignificant impact on downwind receptors (as EPA now asserts), Minnesota's existing glidepath of emissions reductions still supported a finding that no further emission control measures would

[11] 2018 SIP at 5.

[12] Minnesota, of course, could have taken a different approach, and might have used some of these flexibilities, had EPA indicated during the statutory review period that it was considering disapproving prong 2 of Minnesota's SIP.

[13] 2018 SIP at 5-9.

[14] *Id.*

[15] *Id.* at 8-9.

[16] *Id.* at 9-12; *see also id.* at 13.

be needed to address this impact. EPA did not meet its obligation to approve or deny Minnesota's complete and approvable SIP within 12 months of submittal.

Approximately three years after EPA's deadline to approve the Minnesota SIP, EPA proposed to disapprove Minnesota's SIP on February 22, 2022, along with SIPs from 18 other states.[17] EPA did not identify a technical error in Minnesota's submission or any inconsistency with the Good Neighbor requirements, or even EPA's own framework. In fact, EPA recognized that "the modeling the MPCA used relied on the most recently available EPA modeling at the time the state submitted its SIP submittal."[18] Nonetheless, EPA proposed to reject Minnesota's SIP because EPA chose to rely "on the Agency's most recently available modeling, which uses a more recent base year and more up-to-date emissions inventories, to identify upwind contributions and 'linkages' to downwind air quality problems in 2023 using a threshold of 1 percent of the NAAQS." *Id.* Based on this data, EPA proposed to reject Minnesota's conclusion that it was not linked to a downwind receptor, and to find instead that Minnesota was linked to two maintenance monitors in Cook County, Illinois, one with a maximum contribution of 0.97 ppb and the other 0.79 ppb.[19]

On February 13, 2023, EPA published the SIP Disapproval. In its final rule, EPA approved Minnesota's SIP as to "prong 1" but disapproved Minnesota's SIP as to "prong 2."[20] Rather than use the emissions data and modeling available to Minnesota in 2018, or even emissions data and modeling available at the time of the proposed SIP disapproval, EPA made a number of additional updates to its emissions inventories and model design to construct a new 2016v3 emissions platform, which it used to generate new air quality modeling without seeking public comment to allow affected party input to help the agency assess the accuracy of the new information utilized in the modeling.[21] Minnesota was now no longer linked to two downwind receptors. It was now linked to only a single maintenance-only receptor, at a maximum contribution of 0.85 ppb for 2023.[22]

While EPA also conducted updated modeling for 2026, it did not release this information in the docket for the SIP Disapproval, stating it was "not applicable" and "not used in this final action."[23] EPA subsequently made these results available, however, on EPA's website for its Federal Implementation Plan ("FIP") for 23 states, including Minnesota.[24] Based on EPA's modeling for 2026, Minnesota is not linked to any downwind nonattainment or maintenance-only receptor. In fact, based on EPA's modeling, the sole maintenance-only receptor Minnesota was linked to in 2023 is in attainment by 2026, and Minnesota's largest contribution to any

downwind nonattainment or maintenance-only receptor is just 0.32 ppb.[25] Notably, this modeling assumed no installation of additional pollution controls in Minnesota. The only emissions reductions included from Good Neighbor obligations were an annual reduction of 139 tons NOx from emissions control optimization at EGUs.[26]

II. Grounds for Reconsideration of the SIP Disapproval

Reconsideration is justified under either CAA § 307(d)(7)(B)[27] or Administrative Procedure Act ("APA") § 553(e) (5 U.S.C. § 553(e)).[28] Under CAA § 307(d), reconsideration is *required* "[i]f the person raising an objection can demonstrate to the Administrator that it was impracticable to raise such objection within such time or if the grounds for such objection arose after the period for public comment (but within the time specified for judicial review) and if such objection is of central relevance to the outcome of the rule."[29] Courts have found that an objection was "impractical to raise" "when the final rule was not a logical outgrowth of the proposed rule." *Alon Refining Krotz Springs, Inc. v. EPA*, 936 F.3d 628, 648 (D.C. Cir. 2019) (*per curiam*). In other words, when interested parties would not have "anticipated that the change was possible, and thus reasonably should have filed their comments on the subject during the notice-and-comment period." *CSX Transp., Inc. v. Surface Transp. Bd.*, 584 F.3d 1076, 1080 (D.C. Cir. 2009) (internal quotations omitted). An objection is of central relevance to the outcome of the rule if it "provides substantial support for the argument that the regulation should be revised." *Chesapeake Climate Action Network v. EPA*, 952 F.3d 310, 322 (D.C. Cir. 2020). Under the APA, EPA has "broad discretion to reconsider" its SIP Disapproval "at any time" Under the APA. *Clean Air Council v. Pruitt*, 862 F.3d 1, 8-9 (D.C. Cir. 2017).[30]

Three grounds support reconsideration under either standard. First, EPA's 2016v3 modeling did not have the benefit of Petitioners' or other public comments. As a result, it contains a significant overestimation of 2023 emissions for Minnesota. Second, EPA's 2016v3 modeling of the sole monitor supporting a potential linkage between Minnesota and Illinois is subject to significant bias which, if corrected for, results in the same receptor modeling attainment in 2023. Third, EPA's rejection of prong 2 of Minnesota's SIP was procedurally

[25] *See* Federal "Good Neighbor Plan" for the 2016 Ozone National Ambient Air Quality Standards, https://www.epa.gov/system/files/documents/2023-03/FRL%208670-02-OAR_Good%20Neighbor_Final_20230314_Signature_ADMIN%20%281%29.pdf, at 198 (pre-publication version).
[26] Compare *Id.* at 290, Table V.C.1-1; 291, Table V.C.1-2; and 452, Table VI.B.4.c-1.
[27] 42 U.S.C. § 76076(d)(7)(B).
[28] SIP disapprovals are not automatically subject to the exhaustion requirements of Clean Air Act § 307(d). 42 U.S.C. § 7607(d). This subsection lists 22 categories of agency action subject to the exhaustion requirement. SIP approval and disapproval, separate from issuance of a FIP, as occurred in the SIP Disapproval, is not addressed by any of these 22 categories.
[29] 42 U.S.C. § 7607(d)(7)(B).
[30] *See also Trujillo v. Gen. Elec. Co.*, 621 F.2d 1084, 1086 (10th Cir. 1980) ("Administrative agencies have an inherent authority to reconsider their own decisions, since the power to decide in the first instance carries with it the power to reconsider."); *United Gas Improvement Co. v. Callery Properties, Inc.*, 382 U.S. 223, 229 (1965) ("An agency, like a court, can undo what is wrongfully done by virtue of its order.")

improper because it was based entirely on results EPA obtained in 2023, well past the statutory deadline for Minnesota's SIP submission and EPA's decision approving or disapproving it.

A. Errors in EPA's New Emissions Data and Modeling, Which Were Not Subject to Notice and Comment, Support Reconsideration to Ensure EPA's Decision on Minnesota's SIP is Based on Valid and Accurate Information.

EPA "made a number of updates to [its] inventories and model design to construct a 2016v3 emissions platform which was used to update [EPA's] air quality modeling." SIP Disapproval at 9339. The SIP Disapproval uses "this updated modeling to inform [EPA's] final action on [state] SIP submissions," including Minnesota's. *Id.*

The new emissions inventory and modeling platform are of central relevance to EPA's rule. EPA identifies the 2016v3 platform as designed "to inform [the agency's] final action on these SIP submissions." SIP Disapproval at 9339. For Minnesota, the 2016v3 modeling results are the sole record citation EPA provides for its finding that prong 2 of Minnesota's SIP was "ultimately inadequate." *Id.* at 9357.

While there have been errors in each of EPA's inventories at each stage of the regulatory process, these new errors in the emissions inventory arose only with the publication of the final SIP Disapproval. Under both the APA and the CAA, EPA's rulemaking process requires adequate public notice and an opportunity to comment on the evidence on which EPA intends to rely for its final rules.[31] EPA's emissions inventory and modeling design changes were not made publicly available until EPA published the SIP Disapproval and several supporting documents on the same day. As a result, the public, including Petitioners, did not have the opportunity to review EPA's data and correct errors before then.

In the limited time Petitioners have had to review the 2016v3 data, we have identified significant errors in EPA's estimate of NOx emissions for 2023. As an example, EPA added 2,822 tons of NOx for Northshore Mining Co. – Silver Bay power. These boilers have been idled since October 2019 and are expected to have zero emissions in 2023. EPA itself recognizes that zero emissions are expected at this facility in both its OTP Policy Analysis, Appendix A and in its Unit-Level Allocations and Underlying Data for the Final Rule (both available at https://www.epa.gov/csapr/good-neighbor-plan-2015-ozone-naaqs). Yet EPA made no adjustment to its 2016v3 data, resulting in a significant overestimate of 2023 emissions from Minnesota used by EPA to justify disapproval of the Minnesota SIP. If EPA defends including 2,822 tons of NOx emissions for Silver Bay Power in the baseline actual emissions used to model Minnesota's downwind impact in 2023, then Minnesota's state allowance budget should be

[31] *See Small Ref. Lead Phase-Down Task Force v. EPA*, 705 F.2d 506, 540 (D.C. Cir. 1983) (adding evidence on which EPA relies after the close of the comment period would be "highly improper"); *see also Sierra Club v. Costle*, 657 F.2d 298, 400 (D.C. Cir. 1981) ("If … documents of central importance upon which EPA intended to rely had been entered on the docket too late for any meaningful public comment prior to promulgation, then both the structure and spirit of section 307 would have been violated."); *see also Kennecott Corp. v. EPA*, 684 F.2d 1007, 1019 (D.C. Cir. 1982) (finding EPA had not provided adequate opportunity for public comment on economic modeling placed in the docket only one week before promulgation of its final regulations).

increased to reflect those emissions and Silver Bay Power should receive proportional allowance allocations for the 2023 CSAPR ozone season trading program and beyond. To do otherwise would be internally inconsistent, which is an indication of arbitrary rulemaking.

For Minnesota, EPA's most recent modeling identified a single impacted maintenance monitor in 2023, at which Minnesota's maximum impact was 0.85 ppb. EPA's latest modeling projects this same receptor will be in attainment by 2026 with no reductions from Minnesota other than already "on the books" rules and regulations.[32] In other words, EPA's 2026 modeling confirms Minnesota's 2018 SIP conclusion that "the limits and controls that Minnesota already has in place across the state are sufficient to make it reasonably certain that Minnesota will not significantly contribute to nonattainment or interfere with maintenance in any other state" and that "no further controls or emissions limits are required to fulfill [Minnesota's] responsibilities under the interstate transport provisions for the 2015 ozone NAAQS under prongs 1 and 2 of Section 110(a)(2)(D)(i)(I)."[33]

Given the above considerations, EPA should grant reconsideration to reassess Minnesota's 2018 SIP in light of its own modeling showing that no further emission reductions are needed for Minnesota to satisfy its prong 2 good neighbor obligations.

B. The Sole Monitor that Links Minnesota Models in Attainment for 2023 When Bias is Removed.

Minnesota's only link to a downwind state receptor is the Alsip/Village Garage monitor located in Cook County, Illinois (170310001). This monitor is located near the southern shore of Lake Michigan at a land-water interface with complex meteorology**.** This monitor is currently measuring attainment with the 2015 ozone NAAQS using the 2021 4th highest daily maximum value (68 ppb). However, EPA's air quality modeling predicts that this monitor is at risk of violating the ozone NAAQS and, therefore, designates it as a maintenance-only receptor. Upwind states that interfere with this monitor's maintenance of the ozone NAAQS are linked through prong 2**.** However, if a corrected model predicts the monitor's maximum 2023 design value will attain the 2015 ozone NAAQS, this monitor falls out of the analysis at Step 1 and, since no other monitor links to Minnesota, EPA will have no basis for disapproval of prong 2 of Minnesota's SIP.

In the attached analysis, Alpine Geophysics demonstrates that the Cook County monitor models attainment for the 2015 ozone NAAQS in 2023. Alpine Geophysics evaluated this Cook County monitor and concluded that its location at a land-water interface at the southern shore of Lake Michigan presents highly complex meteorological conditions and ozone photochemistry that complicate the air quality model's ability to replicate ozone concentrations reliably. Of note,

---

[32] *See* Air Quality Modeling Final Rule Technical Support Document, https://www.epa.gov/system/files/documents/2023-03/AQ%20Modeling%20Final%20Rule%20TSD.pdf at 17, Table 3-5 (showing Monitor 170310001 no longer listed as a monitor-only receptor in the 2026 base case).
[33] 2018 SIP at 13.

EPA's application of a 12 km grid resolution in such areas is contrary to EPA's own guidance.[34] Alpine Geophysics reviewed EPA's day-specific model performance for the estimation of ozone concentrations on days EPA used to calculate future year design values and found significant bias in the majority of modeled day values used to designate this monitor site as a maintenance-only receptor. When Alpine Geophysics adjusted for this bias by using daily concentration values within acceptable normalized bias boundaries (+/- 15%), the updated list of top ten days used to designate the Cook County monitor resulted in both its average and maximum design values to be calculated in attainment with the 2015 ozone NAAQS.

When one attaining monitor modeled as a maintenance-only receptor is the sole basis for a state's linkage, a refined level of analysis is particularly important when predicting future design values and significant contribution**.** When that monitor is in a highly complex land-water interface area, it is not surprising for refined analysis to show significant bias**.** In its FIP rulemaking, EPA looked at this impact, but evaluated only one of ten Cook County monitors.[35] In doing so, EPA evaluated the only monitor out of the ten where EPA's performance-based recalculation resulted in a higher design value. As a result, EPA's sensitivity analysis materially understates the significance of the bias impact on the Alsip/Village Garage monitor and this issue remains central to EPA's evaluation of Minnesota's 2018 SIP.

Petitioners also had no ability to evaluate the bias in EPA's 2016v3 modeling of the Alsip/Village Garage monitor prior to EPA's release of its model and supporting data. As a result, this information arose after the close of the public comment period and within the time for judicial review.

Since Petitioners have identified significant bias in the sole receptor on which EPA relies to find a link to Minnesota and reject Minnesota's 2018 SIP, reconsideration is appropriate to evaluate the new information and analysis provided. When reasonably adjusting for the bias in EPA's 2016v3 modeling of that receptor, EPA will be in a position to confirm that Minnesota accurately concluded in 2018 that there are no "potential nonattainment or maintenance receptors significantly impacted by ozone transport from Minnesota in 2023" and that "[t]herefore, Minnesota does not have a responsibility to identify or implement any further controls or emissions limits to reduce downwind ozone contribution."[36]

C. Minnesota's SIP Should Have Been Approved Based on the Data Available at the Statutory Deadlines for Submission or Review.

The Clean Air Act sets out a detailed process for EPA's review of SIPs in CAA § 110(k). 42 U.S.C. § 7410(k). For timely submitted plans that have been deemed complete, like Minnesota's,

---

[34] Modeling Guidance for Demonstrating Air Quality Goals for Ozone, $PM_{2.5}$ and Regional Haze, https://www.epa.gov/sites/default/files/2020-10/documents/o3-pm-rh-modeling_guidance-2018.pdf (Nov. 29, 2018).

[35] *See* Federal "Good Neighbor Plan for the 2015 Ozone National Ambient Air Quality Standards Response to Public Comments on Proposed Rule, https://www.epa.gov/system/files/documents/2023-03/Response%20To%20Comments%20Document%20Final%20Rule.pdf at 196.

[36] 2018 SIP at 9.

EPA has twelve months to act on a plan submission. 42 U.S.C. § 7410(k)(2). For a plan that meets the requirements of the Clean Air Act, "the Administrator shall approve such submittal as a whole." *Id.* at (k)(3). If a portion of the plan revision meets all the applicable requirements, EPA "may approve the plan revision in part and disapprove the plan revision in part" but "[t]he plan revision shall not be treated as meeting the requirements of [the Clean Air Act] until the Administrator approves the entire plan revision as complying with the applicable requirements of [the Clean Air Act]." *Id.* In other words, while EPA has discretion to partially approve a SIP submittal that does not meet all requirements of the Clean Air Act, if a submission meets all requirements of the Act, EPA does not have discretion. It must approve the SIP. *See also Utah Physicians for a Healthy Env't v. Kennecott Utah Copper, LLC*, 191 F. Supp. 3d 1287, 1290 (D. Utah 2016) ("If a SIP satisfies the applicable requirements, EPA must approve it.").

In 2018, Minnesota submitted a timely and approvable SIP. As EPA acknowledges in the SIP Disapproval, Minnesota "was not projected to be linked to any receptor in 2023 in the EPA's 2011-based modeling."[37] Petitioners retained Alpine Geophysics to reanalyze Minnesota's SIP submission considering the best evidence available both at the time of Minnesota's SIP submission and at the time of EPA's statutory obligation to approve or disapprove Minnesota's SIP. As detailed in the attached report, Alpine Geophysics' review confirms that Minnesota's SIP submission: (1) had no material errors; (2) relied on the best science (including emissions data and modeling) available at the time; (3) fully complied with the CAA's requirements and EPA's guidance; and (4) would have been approved had EPA not incorporated information unavailable during the statutory review period. As a result, pursuant to 42 U.S.C. § 7410(k)(2) and (k)(3), by April 1, 2020, EPA had a non-discretionary duty to approve Minnesota's SIP. While EPA missed its statutory deadline, this did not relieve EPA of its duty to approve Minnesota's SIP.

While EPA now finds that "in light of more recent air quality analysis," Minnesota is linked to a single maintenance monitor in Illinois, this is based on information that did not exist at the time of Minnesota's SIP submission nor when EPA had a statutory obligation to approve the SIP. This was also not EPA's first use of untimely information to assess Minnesota's SIP. In 2022, EPA proposed to disapprove Minnesota's SIP "[s]ince new modeling ha[d] been performed by EPA with updated emission data," that EPA proposed "to primarily rely on … to identify nonattainment and maintenance receptors in 2023." Proposed Rule at 9867. As EPA acknowledged at the time, this was "a different method for projecting emissions" than what had been available to Minnesota for it to develop its SIP submittal. *Id.* EPA's repeated changes in emissions inventory and modeling platform after the deadline for SIP submissions and after Minnesota's SIP was deemed complete by EPA effectively moved the goalpost for Minnesota's SIP, undercutting the State of Minnesota's ability to identify the requirements EPA would apply to determine an approvable SIP.

The impact was significant. Minnesota's modeled impact went from contributing "below 1 percent of the NAAQS to receptors in 2023" to contributing "greater than 1 percent of the standards to two maintenance-only receptors in Illinois"[38] in the 2022 proposed SIP Disapproval

---

[37] SIP Disapproval at 9357.
[38] *Id.* at 9867-68.

to now being linked to one maintenance-only receptor in the 2023 SIP Disapproval (assuming no further adjustment for bias or data inaccuracies)). Notably, even using EPA's new data and modeling, Minnesota would still have had no linkage to a downwind maintenance receptor if EPA had not also moved the maximum threshold it indicated it would consider acceptable from 1 ppb to 1% (0.70 ppb).[39] As the D.C. Circuit has held, it is arbitrary and capricious to give states a "constantly moving target," *New York v. EPA*, 964 F.3d 1214, 1224 (D.C. Cir. 2020), let alone two. The language and structure of the Clean Air Act clearly give Minnesota and Petitioners the right to address this new data in the first instance in a SIP amendment, and not in a challenge to a SIP disapproval, as EPA now requires.

Notably, if EPA had followed the CAA procedures, it could have appropriately considered the new information it has developed since 2020, including the 2016v3 modeling it has introduced with the 2023 SIP Disapproval. But EPA cannot rely on its almost three year delay to circumvent the process and procedural protections set forth in the Clean Air Act. Rather, EPA was required to act on the SIP Minnesota submitted. If, after approval, EPA finds that a timely, complete and approved SIP nonetheless is "substantially inadequate … to mitigate adequately the interstate pollutant transport" or otherwise comply with the requirements of the Clean Air Act, "the Administrator shall require the State to revise the plan as necessary to correct such inadequacies." *Id.* at (k)(5). EPA also cannot simply disapprove the state's plan pending a new state submission that incorporated EPA's newly developed information, as the SIP Disapproval effectively does. In the event EPA finds a SIP Call is justified, EPA must first "notify the State of the inadequacies, and may establish reasonable deadlines (not to exceed 18 months after the date of such notice) for the submission of such plan revisions." *Id.* Further, "[s]uch findings and notice shall be public." *Id.* These procedural protections are an important component of the cooperative federalism embodied in the Clean Air Act. As courts have held, "[t]he Clean Air Act is an experiment in federalism, and the EPA may not run roughshod over the procedural prerogatives that the Act has reserved to the states, especially when … the agency is overriding state policy. *Bethlehem Steel Corp. v. Gorsuch*, 742 F.2d 1028, 1036–37 (7th Cir. 1984).

Multiple commenters, including the Minnesota Pollution Control Agency, have raised similar concerns arising from EPA's initial proposal to use 2016v2 modeling to disapprove state SIPs.[40] EPA has attempted to respond to those comments in the RTC, but in doing so, has not addressed the fundamental issue that EPA cannot disapprove a SIP that is approvable based on the information existing at the time that submittals are due, or even at the time EPA's SIP review was statutorily due, and cannot circumvent Minnesota's right to address new data in a SIP amendment, before EPA uses it to disapprove an otherwise approvable SIP. 42 U.S.C. §§ 7410(k)(3) and (5).

---

[39] Minnesota did not rely on the 1 ppb threshold for its SIP submission, but as EPA acknowledged, "[t]he 2018 modeling indicated the state was not projected to contribute above one 1 percent of the NAAQS to a projected downwind nonattainment or maintenance receptor. Therefore, the state may not have considered analyzing the reasonableness and appropriateness of a 1 ppb threshold at Step 2 of the 4-step Step interstate transport framework per the August 2018 memorandum." Proposed Rule at 9867.

[40] *See* RTC at 42-59.

EPA asserts in the SIP Disapproval that its use of new modeling and data did not move the goal post for states because EPA "did not evaluate states' SIP submissions based solely on the 2016v2 emissions platform (or the 2016v3 platform…)" but rather "evaluated the SIP submissions based on the merits of the arguments put forward in each SIP submission." SIP Disapproval at 9366. For Minnesota, however, EPA cites no basis or analysis for its SIP Disapproval other than the 2016v3 modeling results. Having relied on no other information to disapprove Minnesota's SIP, EPA cannot simply assert it had an additional basis with no additional substantiation. As the D.C. Circuit has noted, EPA cannot support its decision on only a "Delphic explanation of [Minnesota's] purported failure to carry its burden of proof." *New York*, 964 F.3d at 1224.

EPA also maintains that data and modeling it developed for the Proposed Rule in 2022, and now additional data and modeling it developed for the SIP Disapproval in 2023, supports a finding that Minnesota's SIP submission is "ultimately inadequate." SIP Disapproval at 9357. But even if this were the case, it does not give EPA a right to disapprove Minnesota's 2018 SIP. For data arising after EPA's statutory deadline to approve Minnesota's SIP, EPA could no longer rely on its obligation to use the "best information available." SIP Disapproval at 9366. Interpreting the Clean Air Act otherwise would not do justice to the cooperative federalism framework Congress established in CAA § 110, and would deprive states of important procedural protections allowing them to control and direct in the first instance, the implementation of the NAAQS within their borders.

The SIP Disapproval misapplies the D.C. Circuit's reasoning in *Wisconsin*, 903 F.3d at 322, when it asserts the SIP submission deadline is "'procedural'" and that to limit EPA's decision to information available at the time of the SIP submission or EPA's statutory review deadline would elevate it above requirements "'central to the regulatory scheme.'" SIP Disapproval at 9366 (quoting *Wisconsin*, 903 F.3d at 322. Neither *Wisconsin*, nor the case on which it relies, *Sierra Club v. EPA*, 294 F.3d 155 (D.C. Cir. 2002), addressed the issue presented here. In *Wisconsin*, the court was responding to an argument that EPA should have selected 2011 as its analytic year even though that year had already passed. In *Sierra Club*, the court was responding to a contention that EPA's ability to extend a SIP submittal deadline should support its authority to extend attainment deadlines. Here, EPA argues for an exception that would swallow the rule. If EPA could simply withhold ruling on a SIP until the State's information had become stale, and then disapprove the SIP and issue a FIP based on the "best available information," the cooperative federalism structure of the NAAQS would be an empty shell.

This is also not a situation like that which arose in *EME Homer City Generation, L.P. v. EPA,* 795 F.3d 118 (D.C. Cir. 2015). There, EPA had approved state SIPs in reliance on the Clean Air Interstate Rule ("CAIR"), which was subsequently found to have "more than several fatal flaws" by the D.C. Circuit. *North Carolina v. EPA*, 531 F.3d 896, 901 (D.C.Cir.2008) (*per curiam*). In addressing whether this ruling allowed EPA to "correct" its earlier SIP approvals under 42 U.S.C. § 7410(k)(6), the D.C. Circuit found EPA could do so, but only due to the unique circumstances of that case. *EME Homer City Generation*, 795 F.3d at 135 n.12 ("Our conclusion on Subsection 7410(k)(6) is limited to the unusual circumstances here, in which a federal court says that EPA lacked statutory authority at the time to approve a SIP."). Notably, the D.C. Circuit

did not decide whether EPA could rely on Clean Air Act §110(k)(6) to disapprove an approved SIP "in any other circumstances," and stated that its holding in particular "should not be read to diminish the scope or force of Subsection 7410(k)(5), which provides that whenever 'the Administrator finds that the applicable implementation plan for any area is substantially inadequate ... the Administrator shall require the State to revise the plan as necessary to correct such inadequacies.'" *Id.* (quoting 42 U.S.C. § 7410(k)(5)).

While in *EME Homer,* EPA had already approved several state SIPs, and in this rulemaking EPA has not yet approved Minnesota's SIP, this is a distinction without a difference. Minnesota submitted its SIP on October 1, 2018. It was deemed complete April 1, 2019.[41] EPA's period for review therefore ended April 1, 2020. As described in the Proposed Rule, Minnesota's SIP submission complied with the Clean Air Act and EPA's guidance for developing an interstate transport SIP for the 2015 ozone NAAQS. 87 Fed. Reg. at 9848-49. As detailed in the attached report, Alpine Geophysics' review confirms that Minnesota timely submitted an approvable SIP. By April 1, 2020, EPA had a statutory duty to approve Minnesota's SIP.

EPA's reliance on its 2016v3 modeling platform (which was not available to the public or interested parties) to reject the conclusions Minnesota reached based on the information that was available to all parties at the time is clearly of central relevance. Had EPA acted by its statutory deadline, Minnesota would have an approved SIP today. Further, while Petitioners have previously commented on the approvability of Minnesota's SIP, the basis for EPA's partial SIP Disapproval for Minnesota, including its decision to rely on its newer 2016v3 modeling platform, was not made public until the final rule. These grounds therefore arose after the close of the public comment period but before the time for judicial review. Reconsideration is therefore appropriate to address this procedural anomaly for Minnesota.

On reconsideration EPA should approve Minnesota's 2018 SIP based on the information that was available to EPA for its statutory review. The agency may then reassess whether, based on the information available today, including the above data and bias corrections, Minnesota's SIP remains sufficient to comply with prong 2 of the state's Good Neighbor obligations. For the reasons explained herein, EPA should find that the 2018 SIP was and is adequate to comply with prong 2.

III. Grounds for Stay of the SIP Disapproval

EPA has authority to stay the SIP Disapproval both pending reconsideration and pending judicial review. First, if the SIP Disapproval is subject to CAA § 307(d), a stay pending reconsideration can be granted for three months. Second, EPA has authority under the APA to stay the SIP Disapproval pending judicial review.

[41] *See* https://www3.epa.gov/airquality/urbanair/sipstatus/reports/mn_infrabypoll.html

A. A Stay Under CAA § 307(d)(7) is Appropriate.

The Clean Air Act provides that, if EPA grants reconsideration of a rule, "[t]he effectiveness of the rule may be stayed during such reconsideration…by the Administrator or the court for a period not to exceed three months." 42 U.S.C. § 7607(d)(7)(B). If the SIP Disapproval is subject to CAA § 307(d), a stay pending reconsideration is justified here.

EPA issued a final rule based primarily on emissions data and modeling that it did not make publicly available before issuance of the final rule. Even upon publication, EPA's release of data was partial and inadequate to reconstruct the modeling that EPA used for its final determinations. Obtaining the data and checking its accuracy has taken several weeks. It would take many more weeks to rerun EPA's modeling to confirm that the results support reversal of EPA's disapproval of prong 2 of Minnesota's SIP. It will likely take a similar amount of time to evaluate the evidence of bias Petitioners are submitting to confirm that it too, supports approval of Minnesota's SIP.

A stay will also not unduly impact downwind states. Minnesota is not modeled to interfere with attainment for any downwind state. Under EPA's most recent modeling, Minnesota is linked only to a single maintenance-only receptor, the most recent monitored design value of the monitor at this location was in attainment, and EPA's modeling for 2026 shows the receptor will model attainment as well with only minimal reductions from Minnesota. As EPA has itself emphasized, the SIP Disapproval does not require any action from the states.[42]

While a stay of the effective date of the SIP Disapproval for Minnesota would also prevent EPA from applying its FIP to Minnesota at the start of the upcoming ozone trading season, which is scheduled to start May 1, 2023, this is not likely to be relevant. In a recent filing, EPA has stated that the FIP is not likely to be effective until "late June to early July."[43] If EPA timely takes action on this reconsideration, this is well within the time EPA would need to conduct reconsideration. Further, while EPA has interpreted the CAA to require it "to address good neighbor obligations as expeditiously as practicable and no later than the next attainment date," RTC at 445, granting a stay of Minnesota's SIP denial pending reconsideration will not interfere with that goal. Minnesota is modeled to impact only a single maintenance-only monitor. As the D.C. Circuit has recognized, this 'may be a valid reason" to postpone addressing emission reductions until even after the next attainment date. *North Carolina v. EPA*, 531 F.3d 896, 912 (D.C. Cir. 2008). A reasonable stay to address reconsideration falls well within EPA's discretion.

B. EPA Should Stay the Effective Date of the SIP Disapproval Pending Judicial Review.

EPA can consider a stay of the entire SIP Disapproval for all affected states. Under the APA, EPA may stay the effective date of the SIP Disapproval pending judicial review when "justice

---

[42] *See, e.g.*, 2015 Ozone NAAQS Interstate Transport SIP Disapproval – Response to Comments ("RTC") at 466.
[43] Respondents' Consolidated Response in Opposition to the Motions for Stay of the Final Rule, *Texas v. EPA*, Case No. 23-60069, Doc. 109, at 12 (5th Cir. Filed March 27, 2023).

so requires." 5 U.S.C. § 705. Several Petitioners are filing a petition for judicial review of EPA's partial disapproval of Minnesota's SIP contemporaneously with this petition for reconsideration and stay. Multiple other petitions have already been filed for judicial review, including petitions by Arkansas, Kentucky, Oklahoma, Texas, Utah, and Wyoming. More are likely. These cases are already spread across four circuits, and additional litigation may expand the number of courts further.

The effective date of the SIP Disapproval is March 15, 2023. This effective date is significant for both legal and practical reasons. Legally, it will force EPA to promulgate a FIP within two years (though in this case EPA has already finalized its FIP). 42 U.S.C. § 7410(c)(1). States will also be required to prepare SIP revisions if they are interested in addressing the errors in EPA's analysis. Further, the significant legal flaws in EPA's SIP Disapproval discussed above, coupled with the technical and legal concerns it raises, make it likely that judicial review will result in a remand if not vacatur of the current SIP Disapproval. As a result, to avoid the unnecessary expenditure of EPA resources on a FIP, state resources on SIP revisions, and the resources of the public and regulatory industries in addressing a FIP that is likely to not be required, justice requires that the SIP Disapproval be stayed pending judicial review.

Further, while EPA is not bound to apply the same four-factor analysis used by courts for granting a judicial stay pending review, these factors indicate support for EPA in granting a stay of the SIP Disapproval. Under this standard, the considerations for a stay are:

(1) whether the stay applicant has made a strong showing that he is likely to succeed on the merits;

(2) whether the applicant will be irreparably injured absent a stay;

(3) whether issuance of the stay will substantially injure the other parties interested in the proceeding; and

(4) where the public interest lies.

Nken v. Holder, 556 U.S. 418, 434, 129 S.Ct. 1749, 173 L.Ed.2d 550 (2009) (citation omitted). These "four considerations are factors to be balanced and not prerequisites to be met." *State of Ohio ex rel. Celebrezze v. Nuclear Regul. Comm'n*, 812 F.2d 288, 290 (6th Cir. 1987).

1. Petitioners Have Made a Strong Showing They Are Likely to Succeed on the Merits

There is no fixed probability of success the agency must find in applying these considerations. "Ordinarily the party seeking a stay must show a strong or substantial likelihood of success. However, at a minimum the movant must show 'serious questions going to the merits and irreparable harm which decidedly outweighs any potential harm to the defendant if a [stay] is issued.'" *Id. (quoting In re DeLorean Motor Company*, 755 F.2d 1223, 1229 (6th Cir.1985)).

As discussed above, the SIP Disapproval has substantive and procedural flaws, each of which individually, and more so when combined, demonstrate "a high probability of success on the merits." *Ohio ex rel. Celebrezze v. Nuclear Regul. Comm'n.*, 812 F.2d 288, 290 (6th Cir.1987). Substantively, EPA's partial SIP Disapproval for Minnesota was based on an incorrect set of emissions data and biased modeling results that, when adjusted, support Minnesota's original conclusion that the state is not linked to downwind nonattainment or interference with maintenance and, even if linked, does not need to impose additional emission reductions to satisfy its Good Neighbor obligations. Procedurally, EPA did not follow the process required by the Clean Air Act for reviewing and approving Minnesota's SIP. In doing so, EPA deprived the State and Petitioners of the ability to address EPA's concerns in a SIP Call process.

Other flaws in the SIP Disapproval also strongly support a showing of likely success on the merits in a judicial challenge. In particular, we call to the agency's attention: (a) EPA's impermissible reliance on new data to disapprove prong 2 of Minnesota's SIP without providing adequate notice and an opportunity for public comment; and (b) the SIP Disapproval's subversion of the well-established and vital cooperative federalism underlying the entire Clean Air Act and in particular, the NAAQS.

a. *EPA Cannot Base its SIP Disapproval on Information that was Not Subject to Adequate Notice and Public Comment*

Under both the Administrative Procedure Act ("APA") and the CAA, EPA's rulemaking process requires adequate public notice and an opportunity to comment. *Small Ref.*, 705 F.2d at 547. This includes providing the public with the evidence on which EPA intends to rely. *Id.* at 540. Adding evidence on which EPA relies after the close of the comment period is "highly improper." *Id.* at 540; *see also Sierra Club*, 657 F.2d at 400 ("If … documents of central importance upon which EPA intended to rely had been entered on the docket too late for any meaningful public comment prior to promulgation, then both the structure and spirit of section 307 would have been violated."). Even reconsideration cannot cure an inadequate opportunity for notice and comment. *U. S. Steel v. EPA*, 595 F.2d 207, 214 (5th Cir. 1979) ("Permitting the submission of views after the effective date is no substitute for the right of interested persons to make their views known to the agency in time to influence the rulemaking process in a meaningful way.") (Internal quotations omitted).

In the SIP Disapproval, EPA "made a number of updates to [it's] inventories and model design to construct a 2016v3 emissions platform which was used to update [EPA's] air quality modeling." SIP Disapproval at 9339. The SIP Disapproval used "this updated modeling to inform [EPA's] final action on [Minnesota's] SIP submissions." *Id.* The details of these emissions inventory and modeling design changes were first described to the public in the SIP Disapproval and associated documents made publicly available the same day.[44] Even then, EPA did not make public its 2026 modeling results, reserving these for finalization of the FIP several weeks later.

[44] Even then, the supporting data and modeling platform were not made electronically available and needed to be requested by the public, which added several more weeks to gain access.

This data and modeling were clearly of central importance to EPA's disapproval of prong 2 of Minnesota's SIP. In fact, they are the sole basis for EPA's disapproval. *See* SIP disapproval at 9357 (finding Minnesota's analysis "ultimately inadequate" in light of EPA's "more recent air quality analysis"); *see also id*. (disapproving prong 2 of Minnesota's SIP because "[i]n the 2016v3 modeling, Minnesota is projected to be linked above 1 percent of the NAAQS to one maintenance-only receptor"). As a result, EPA was required to provide the public advance notice of its new data and an opportunity for meaningful public comment.

EPA's publication of its revised emissions inventory and modeling the day of the SIP Disapproval did not satisfy this requirement. In *Kennecott Corp. v. EPA*, 684 F.2d 1007, 1019 (D.C. Cir. 1982), the D.C. Circuit found EPA had not provided adequate opportunity for public comment on economic modeling placed in the docket only one week before promulgation of its final regulations. Here, EPA did not make its new emissions data and modeling publicly available until the *day* it published its final SIP Disapproval.

It is not enough to say that Petitioners had the opportunity to comment on EPA's previous version of the emissions data and modeling, or that EPA's latest data simply "incorporates comments generated during the public comment period." SIP Disapproval at 9366. As the D.C. Circuit stated in *Chesapeake*, 952 F.3d at 320, it would be an "unreasonable burden on commenters not only to identify errors in a proposed rule but also to contemplate why every theoretical course of correction the agency might pursue would be inappropriate or incorrect." The new data and modeling on which EPA relies for the SIP Disapproval differs significantly from that which was in the public record. Based on EPA's own summary of the data, Minnesota's largest contribution to a downwind maintenance receptor changed from 0.97 ppb to 0.85 ppb based on EPA's changes. *Compare* Proposed Rule at 9868 *with* SIP Disapproval at 9354. Since EPA's own adopted significant contribution threshold in the SIP Disapproval is 0.7 ppb, a change of 0.12 ppb is clearly significant.[45]

Under both the CAA and the APA, EPA was required to provide notice and an opportunity for public comment on its 2016v3 data. There is no question that EPA provided no notice or opportunity for comment. As a result, there is a high likelihood that Petitioners would be likely to prevail on the merits of a judicial challenge. This strongly supports EPA issuing a stay of the effective date of the SIP Disapproval pending judicial review.

b. *EPA Undermined State Primacy by Disapproving Minnesota's SIP Despite its Adherence to the Requirements of the Clean Air Act.*

As EPA acknowledges, "[t]he CAA establishes a framework for state-Federal partnership to implement the NAAQS based on 'cooperative federalism.'" SIP Disapproval at 9367. Under this model, "the Federal Government establishes broad standards or goals, states are given the

[45] EPA's 2016v3 modeling did not just result in significant changes to EPA's assessment of Minnesota's potential impact on downwind states. Six states (Arizona, Iowa, Kansas, New Mexico, Tennessee, and Wyoming) had their status as linked states change entirely. *See* Air Quality Modeling Technical Support Document 2015 Ozone NAAQS SIP Disapproval Final Action, https://www.regulations.gov/document/EPA-HQ-OAR-2021-0663-0017 at 24.

opportunity to determine how they wish to achieve those goals, and if states choose not to or fail to adequately implement programs to achieve those goals, a Federal agency is empowered to directly regulate to achieve the necessary ends." *Id.* Thus, "states have the obligation and opportunity in the first instance to develop an implementation plan to achieve the NAAQS under CAA section 110" and "EPA will approve SIP submissions under CAA section 110 that fully satisfy the requirements of the CAA." *Id.* As the Supreme Court has held: "[e]ach State is given wide discretion in formulating its plan, and the Act provides that the Administrator 'shall approve' the proposed plan if it has been adopted after public notice and hearing and if it meets [the CAA's] criteria." *Union Elec. Co. v. EPA*, 427 U.S. 246, 250 (1976) (*quoting* 42 U.S.C. § 7410(a)(2)).

EPA departed from this framework when it proposed a SIP disapproval based, not on any inaccuracy in Minnesota's evaluation of the data, but on EPA's preference for a different modeling platform and emissions inventory. EPA does not have the authority to condition SIP approval on the state's adoption of EPA's preferred approach, or to supplant Minnesota' interpretation of how best to achieve the goals of the CAA, as long as Minnesota complies with the requirements of the CAA.

EPA's position is predicated on an incorrect summary of its role in the SIP review process and the relevant case law. First, EPA's role is not "secondary" only in that "it occurs second in time." RTC at 425 (internal quotations omitted). EPA relies on *EPA v. EME Homer City Generation*, LP, 572 U.S. 489 (2014) for this proposition, but the case does not support EPA's position. It must be remembered that *EME Homer* involved EPA's authority to promulgate a FIP after EPA had already disapproved SIPs.[46] As a result, the Court did not address EPA's statutory duty to approve a timely and complete SIP submission, which is the issue here. The Court's "interpretations of CAA section 110(a)(2)(D)(i)(I)" on which EPA relies must be read in this light. RTC at 426. The Court upheld interpretive choices EPA made when issuing a FIP. The Court did not say EPA could delay approval until new information became available that supported its disapproval of the SIP.

Second, EPA is wrong to imply that *EME Homer* undermines the long line of cases setting out EPA's secondary (in substance, not just in time) role in developing plans to implement the NAAQS. In fact, the Supreme Court continues to cite these cases for their interpretation of EPA's role. *See West Virginia v. EPA*, 213 L. Ed. 2d 896, 142 S. Ct. 2587, 2600 (2022) ("EPA … does not choose which sources must reduce their pollution and by how much to meet the ambient pollution target. Instead, Section 110 of the Act leaves that task in the first instance to the States, requiring each 'to submit to [EPA] a plan designed to implement and maintain such standards

[46] *See EME Homer*, 572 U.S. at 507 ("The gravamen of the State respondents' challenge ***is not that EPA's disapproval of any particular SIP was erroneous***. Rather, respondents urge that, notwithstanding these disapprovals, the Agency was obliged to grant an upwind State a second opportunity to promulgate adequate SIPs once EPA set the State's emission budget. ***This claim does not depend on the validity of the prior SIP disapprovals***. Even assuming the legitimacy of those disapprovals, the question remains whether EPA was required to do more than disapprove a SIP, as the State respondents urge, to trigger the Agency's statutory authority to issue a FIP.") (emphasis added).

within its boundaries.'") (*quoting Train v. Natural Resources Defense Council, Inc.*, 421 U.S. 60, 65 (1975)).

The SIP Disapproval and RTC makes clear that EPA's disapproval of prong 2 of Minnesota's SIP was not based on a determination that Minnesota's SIP failed to meet the statutory requirements of CAA, but because EPA wanted to apply "a consistent set of policy judgments across all states for purposes of evaluating interstate transport obligations and the approvability of interstate transport SIP submissions for the 2015 ozone NAAQS under CAA section 110(a)(2)(D)(i)(I)." SIP Disapproval at 9339; *see also id.* at 9340 ("Effective policy solutions to the problem of interstate ozone transport going back to the NOx SIP Call have necessitated the application of a uniform framework of policy judgments to ensure an 'efficient and equitable' approach.") (quoting *EME Homer*, 572 U.S. at 519); RTC at 425-426. This was error. EPA's assessment of a SIP is to be based on whether the SIP compiles with the requirements of the CAA, not on EPA's policy preferences or desire for efficiency. Only after a state fails to comply with its statutory requirements can EPA impose what it believes best to achieve the substantive objective of the Act.

Because EPA's SIP Disapproval is based on improper factors that undermine the core cooperative federalism embodied in CAA § 110, Petitioners are likely to prevail on the merits of a judicial challenge. This further supports EPA issuing a stay of the effective date of the SIP Disapproval pending judicial review.

2. Petitioners Will Suffer Irreparable Harm from a Denial of Stay.

Relevant factors for evaluating the harm which will occur include: (1) the substantiality of the injury alleged; (2) the likelihood of its occurrence; and (3) the adequacy of the proof provided. In evaluating the harm which will occur both if the stay is issued and if it is not, the court must look to three factors: the substantiality of the injury alleged, the likelihood of its occurrence, and the adequacy of the proof provided. *Ohio ex re. Celebrezze*, 812 F.2d at 290 (*citing Cuomo v. United States Nuclear Regulatory Commission*, 772 F.2d 972, 974 (D.C.Cir.1985)).

The SIP Disapproval poses substantial and imminent injuries to Petitioners. As discussed in Section II above, the data which EPA should have used to evaluate Minnesota's SIP (see Section II.C), the best available data today, when flaws are addressed (see Sections II.A and B), and even the most likely future data (see Section II.D) strongly support a finding that Minnesota is not significantly contributing to nonattainment or interfering with maintenance of the 2015 ozone NAAQS in any state. EPA's SIP denial is predicated on the erroneous conclusion that there *is* interference with maintenance. This places the entire State of Minnesota in an erroneous state of non-compliance with the Good Neighbor requirement of the Clean Air Act.

EPA's SIP Disapproval also forces EPA to promulgate emission reductions through a FIP. 42 U.S.C. § 7410(c). EPA has already finalized just such a rulemaking. This leaves no time for reconsideration or judicial review to run its course before Petitioners are injured by the FIP, let alone time for Minnesota to remedy EPA's issues with the submitted SIP. Petitioners submitted detailed comments on the FIP identifying numerous substantial injuries from EPA's promulgation

of its Proposed FIP that are likely to occur, and supported by substantial evidence, including detailed technical reports.[47] While EPA made substantial modification to the FIP in response to comments, which Petitioners appreciate reflects considerable work on the Agency's part following the public comment period and has addressed many significant issues with the proposed FIP, the final FIP nonetheless includes significant obligations for Petitioners' electric generating units ("EGUs"), starting in the current 2023 ozone trading season (which begins this year). Even Petitioners without EGUs are substantial consumers of electricity, meaning that they will likely bear much of the burden of the higher costs needlessly imposed on Minnesota power producers because of the FIP. Further, while the Proposed FIP is a separate rulemaking, EPA has itself identified the SIP Disapproval as both a necessary step in issuance of a final FIP[48] and the stay of a SIP disapproval that is the basis for a FIP is an appropriate remedy for injuries arising from the FIP itself. *See EME Homer City Generation, L.P. v. EPA*, 696 F.3d 7, 44 n.6 (D.C. Cir. 2012) (Rogers, J., dissenting), *rev'd on other grounds,* 572 U.S. 489 (2014) ("If [states] wish to avoid enforcement of the Transport Rule FIPs because they contend EPA's SIP disapprovals were in error, the proper course is to seek a stay of EPA's disapprovals in their pending cases; if granted, a stay would eliminate the basis upon which EPA may impose FIPs on those States.") (citing 42 U.S.C. § 7410(c)(1)(B)).

3. Staying the SIP Disapproval will not Significantly Injure Other Parties.

As discussed in Section III.A above, the SIP Disapproval does not on its own impose any emission reductions on sources. As a result, a stay will not directly harm any other party. While a stay would also potentially delay the effective date of the FIP, this is unlikely to result in significant injury to other parties. EPA has recently extended a judicially-enforceable deadline to review Good Neighbor SIPs for three states to December 15, 2023 without any mention of public harm from the delay.[49] Even as a stepping stone to a FIP, while a stay will alleviate imminent and irreparable costs, it will not significantly impact NOx emissions. As discussed above, the FIP is unlikely to be effective until after the start of the current ozone trading season, resulting in an attenuated impact on 2023 emissions. Further, even if projected emission reductions for the full 2023 ozone trading season could be achieved, EPA projects total emission reductions from Minnesota of only 139 tons in 2023. This is unlikely to result in any significant impact on the Cook County maintenance monitor.

4. The Public Interest Lies in Granting a Stay.

As courts have held, there is a public interest enjoining inequitable conduct and in minimizing unnecessary costs to be met from public coffers. *See, e.g. B & D Land & Livestock Co. v. Conner*, 534 F. Supp. 2d 891, 910 (N.D. Iowa 2008). Here, the public interest supports a stay.

[47] See Comments of U. S. Steel, EPA-HQ-OAR-2021-0668-0798 (June 27, 2022); Comments of Xcel Energy, EPA-HQ-OAR-2021-0668-0411 (June 23, 2022); Comments of Minnesota Power, EPA-HQ-OAR-2021-0668-0539 (June 23, 2022); Comments of SMMPA, EPA-HQ-OAR-2021-0668-0351 (June 22, 2022); Comments of Cleveland-Cliffs Inc., EPA-HQ-OAR-2021-0668-0405 (June 23, 2022)

[48] 88 Fed. Reg. 9336 at 9362.

[49] *See* Joint Notice of Second Stipulated Extension of Consent Decree Deadlines, Doc. 33, *Downwinders at Risk v. Regan*, Case No. 4:21-cv-3551-DMR (N.D. Cal. Jan. 30, 2023).

As discussed in Section II.A above, EPA's SIP Disapproval was promulgated through the inequitable exclusion of public participation into the data central to EPA's final rulemaking. The result will be costly public expenditures, both by EPA to promulgate an unnecessary FIP and States to either prepare to implement EPA's FIP or prepare revised SIPs, and well as unnecessary costs borne by Petitioners.

While it was an error for EPA to disapprove Minnesota's SIP based on information not in the record at the time of submission, EPA can ameliorate the harm of this error by staying the effect of its SIP disapproval until the merits of the issues above can be fully evaluated and addressed.

IV. Conclusion

The State of Minnesota has expended substantial effort and resources to regulate the emission of NOx within its borders. Those efforts have successfully reduced State impacts on downwind receptors to a point that Minnesota is not a significant contributor to nonattainment or interference with maintenance of the 2015 ozone standard in any state. Based on the best available data and modeling science available at the time, Minnesota assessed its impact on downwind states, as it was required to do under the Clean Air Act, and appropriately concluded that it was not interfering with maintenance of attainment in any state. EPA has identified no error or omission in Minnesota's analysis. Nonetheless, based on data that was not available at the time, and in fact was not available to the public until February 2023, EPA partially disapproved Minnesota's Good Neighbor plan for the sole reason that, based on EPA's own modeling, it found a single maintenance receptor in Cook County, Illinois that Minnesota state emissions were impacting at a maximum level of 0.85 ppb. Neither Minnesota, nor Petitioners, were given an opportunity to comment on EPA's modeling, fully evaluate it, or even see it, until EPA published its final SIP Disapproval. While a complete analysis of EPA's modeling would require months, based on Petitioners' review of the data specific to them, and based on expert evaluations by Alpine Geophysics of the modeling and data EPA has provided, EPA's results likely overstate the impact Minnesota is having on the Cook County monitor. Because Petitioners have provided new information that reveals flaws in EPA's emissions inventory for Minnesota and bias in EPA's modeling of the lone monitor that links Minnesota emissions to a downwind state, Petitioners have raised material new data undermining the central basis for EPA's disapproval of prong 2 of Minnesota's SIP. Petitioners therefore request that EPA grant reconsideration of its partial SIP disapproval for Minnesota and approve Minnesota's 2018 SIP. Further, to avoid the significant and irreparable harm to Petitions arising from EPA's erroneous disapproval of prong 2 of Minnesota's SIP, EPA should stay the effectiveness of its SIP Disapproval as applied to prong 2 of Minnesota's SIP pending reconsideration and pending judicial review.

DOCUMENT OBJECTIVE

The objective of this document is for Alpine Geophysics, LLC to provide technical review and professional opinion of Minnesota Pollution Control Agency's (MPCA) SIP revision to address Clean Air Act (CAA) Section 110(a)(2)(D)(i)(I) and the Environmental Protection Agency's (EPA) final action to disapprove the Minnesota State Implementation Plan (SIP) published on February 13, 2023 in the Federal Register.

This document is formatted into three sections that discuss our review and assessment of the following issues:

A. Whether, given time to reassess, MPCA could demonstrate no linkage and/or no significant impact on attainment and maintenance in downwind states;
B. Whether U.S. EPA's revisions to its modeling approach since MPCA's SIP submittal were ancillary; and
C. Whether the Minnesota Pollution Control Agency's state implementation plan revision was approvable based on the state of the science at the time it was submitted to U.S. EPA.

At the end of this document, we also provide a summary of conclusions (Section D) and a regulatory and legislative timeline of actions taken on Minnesota's 2015 ozone SIP for reference (Section E).

A. Given time to reassess, MPCA could demonstrate no linkage and/or no significant impact on attainment and maintenance in downwind states.

EPA provided little time for MPCA to review the significant amount of technical information and associated calculations that were used to justify their disapproval of the Minnesota SIP, especially since EPA used a distinct and largely unrelated modeling platform, emissions inventory, and air quality model to justify its action instead of assessing the platform submitted by MPCA in support of its SIP. Notwithstanding the fact that four years and four months passed since the original Minnesota SIP was submitted to EPA, had appropriate time been given to MPCA to review and address EPA's final disapproval, MPCA could have addressed significant flaws in EPA's modeling that EPA itself should have addressed prior to finalizing any SIP disapproval.

It is our opinion that the U.S. EPA should have approved the MPCA's SIP when it was submitted in 2018. However, since EPA has put forward new modeling, we have reviewed this modeling and found several issues with the emissions that EPA used in the new modeling that weigh against using it as a basis for disapproving the Minnesota SIP.

1. EPA inappropriately revised the emission inventory and conducted new air quality modeling for SIP disapprovals without allowing a meaningful opportunity for stakeholder review and comment.

EPA's revisions to the emission inventory used in the modeling it previously has conducted for historic transport rules raises an administrative concern about public review and comment.

EPA notes in the proposed SIP disapprovals that, after the modeling it conducted in support of earlier transport rules, e.g., CAIR, CSAPR, CSAPR Update, CSAPR Closeout, and Revised CSAPR Update, the agency revised the emission inventory used in the modeling to assess the efficacy of prior transport rules. EPA conducted new modeling using this revised inventory and 2016v2 modeling platform. The agency describes the process as follows:

> *Following the Revised CSAPR Update final rule, the EPA made further updates to the 2016 emissions platform to include mobile emissions from the EPA's Motor Vehicle Emission Simulator MOVES3 model and updated emissions projections for electric generating units (EGUs) that reflect the emissions reductions from the Revised CSAPR Update, recent information on plant closures, and other sector trends. The construct of*

> *the updated emissions platform, 2016v2, is described in the emissions modeling technical support document (TSD) for this proposed rule.*[1]

In December 2021, and in response to EPA requests for inventory review and updates[2,3,4], MPCA and other stakeholders submitted detailed comments on the 2016v2 emission inventory platform to correct errors that existed in that platform. EPA's declared efforts to revise this emission inventory platform at this time raised the question about whether EPA intended to update the modeling that has been used as the basis for the SIP disapprovals and the proposed FIP – but only in support of the final rule. EPA's own summary[5] of the comment process includes the statement that "by spring of 2021 it was necessary to make updates to the inventories to perform credible / defensible modeling in CY2021". In this summary, numerous and significant emission, control, and projection factor changes were requested and only with release of the final SIP denials were the changes shared by EPA for review.

As part of these comments, MPCA submitted comments on the 2016v2 emissions modeling platform (EMP) relative to three areas of improvement within Minnesota:

1. Non-electricity generation stationary (non-EGU) point source emissions controls
2. Future year emissions projections for various point and non-point inventory sectors
3. Stationary point EGU growth rate differences between the ERTAC vs IPM models

Non-EGU point source emissions controls

LADCO worked with member states to identify the highest-emitting sources and applicable control technology information for non-EGU stationary point sources in the region. They generated a spreadsheet with the highest-emitting non-EGU sources in 2016 for each LADCO state, including Minnesota, which also included state updates on emissions control information for listed sources.

A provided spreadsheet identified control information and future emission rate changes for several Minnesota sources within the 2016v2 EMP. The control information identified accounts for the installation of low NOx burners at the taconite facilities in Minnesota as part of the Regional Haze Taconite FIP. Based on MPCA estimates, just under 11,000 tpy in NOx reductions were expected due to the controls required by the Taconite FIP. MPCA noted the importance of

having these significant reductions included in the EPA EMP for non-EGUs and requested that EPA do so.

Below is a summary of approximate NOx emission changes for these sources.

- 2,100 tpy at Minorca Mine
- 2,300 tpy at Hibbing Taconite
- 700 tpy at United Taconite
- 3,600 tpy at US Steel Keetac
- 2,100 tpy at US Steel Minntac

Future year emissions projections for various point and non-point inventory sectors

LADCO used US EPA-generated emissions projection reports and identified a list of SCCs that they believed had incorrect future year projection rates. The 2016v2 EMP projection rates were not found consistent either with real-world emissions trends or regional emissions projection information. It was requested that EPA replace the 2016v2 EMP projections for these sources with the updated rates provided by LADCO.

A spreadsheet was provided that included the list of the SCCs with alternative projection information and LADCO comments on the sources of the alternative information.

Stationary point EGU growth rate differences between the ERTAC vs IPM models

LADCO recognized that EPA used the Integrated Planning Model (IPM) to estimate future year EGU emissions, and that the IPM projection methodology differed from the Eastern Research Technical Advisory Committee (ERTAC) EGU model that is endorsed by the MJOs and most of the states in the eastern half of the country. Minnesota noted support for the use of ERTAC EGU projections in the 2016v2 EMP and asked EPA to consider replacing IPM projections with ERTAC EGU projections for sources in the LADCO region in subsequent modeling platforms.

While most states urged EPA to rely on modeling that accurately reflects current on-the-books regulatory requirements and up-to-date emission inventories, they also strenuously object to the possibility that EPA would conduct any such additional modeling to support a final rule. Furthermore, these states object to EPA not providing the opportunity for those data to be reviewed, analyzed, commented upon, and having those comments addressed by EPA in advance of any final decision on the subject SIP disapproval (or for that matter the related FIP). These concerns were also expressed in July 2021 by several MJOs (WESTAR, LADCO, SESARM, MARAMA, and CENSARA).[6]

ALPINE GEOPHYSICS

EPA's Previously Unreleased 2016v3 Modeling Platform

EPA's newest emissions inventory and modeling platform are of central relevance to EPA's final rule. The SIP Disapproval itself identifies EPA's "updates to the 2016v2 inventories and model design to construct a 2016v3 emissions platform which was used to update the air quality modeling" and used "this updated modeling to inform its final action on these SIP submissions.[7]" These data and modeling in fact form the basis for EPA's final disapproval of Minnesota's SIP[8] (finding Minnesota's analysis "ultimately inadequate" in light of EPA's "more recent air quality analysis"). This issue also arose only with the publication of the final SIP Disapproval. EPA's publication of its revised emissions inventory and modeling did not occur until then, and states had no access to the data, the modeling, or even the results of EPA's modeling until that time.

In the limited time that states have had with the modeling data, significant errors have been identified. A robust public comment process for these data is necessary to correct all significant errors to ensure that EPA's regulatory decisions are based on valid and accurate information. Within Minnesota alone, some of these errors include the following:

- EPA incorrectly included NOx emissions of 2,822 tons in 2023 for Northshore Mining Co. – Silver Bay in the future year air quality modeling and associated significant contribution calculations but not in the engineering analysis used to calculate state level EGU budgets. The subject boilers have been idled since October 2019 and are expected to have zero emissions in 2023;

- EPA predicts zero emissions at Minnesota Power's Laskin Energy Center units that have been converted to natural gas and expect continued MISO dispatch to support the renewables transition and regional grid needs / constraints;

These errors, and many like these presumed in other states in the modeling platform, may significantly impact the results of EPA's analysis and could be the difference in nonattainment and maintenance determinations or whether Minnesota is having a downwind effect on the lone Illinois maintenance monitor that subjects Minnesota to the Good Neighbor provisions of the Clean Air Act.

It is our opinion that the absence of inclusion of Minnesota's and other stakeholder's valid EMP revision submissions, as requested by EPA, and without a rerun of the air quality model in both the base and projection year simulations, EPA cannot appropriately identify monitors as nonattainment or maintenance, and in turn, cannot calculate upwind state significant contribution metrics from these same data. Non-EGU emission controls and their associated NOx emission reductions as documented and submitted by MPCA, could be enough to change

[7] 88 FR 9339
[8] 88 FR 9357

nonattainment designations and linked significance using an updated platform, and needs to be considered before making any final decision on denial of MPCA's SIP.

2. The Cook County, Illinois monitor to which Minnesota is linked, is located at the interface of land and water along Lake Michigan and is not properly characterized by EPA's supporting modeling.

EPA did not make a bias adjustment for the only receptor that EPA found "links" Minnesota to downwind interference with maintenance. Observed values at this location (the Alsip/Village Garage monitor) demonstrate significant model overprediction, justifying the need for adjustments to address bias. While EPA has recently investigated bias in southern Lake Michigan, this assessment selectively analyzed only one monitor, which was not representative of the bias observed at the Village Garage monitor. The failue to adequately address bias in EPA's modeling resulted in an overprediction of ozone. Adjusting for this bias supports the conclusion that the Alsip monitor models in attainment of the 2015 ozone NAAQS and therefore Minnesota is not interfering with maintenance at this monitor. EPA's ozone attainment modeling guidance states that:

> *"[t]he most important factor to consider when establishing grid cell size is model response to emissions controls. Analysis of ambient data, sensitivity modeling, and past modeling results can be used to evaluate the expected response to emissions controls at various horizontal resolutions for both ozone and PM2.5 and regional haze. If model response is expected to be different (and presumably more accurate) at higher resolution, then higher resolution modeling should be considered. If model response is expected to be similar at both high and low(er) resolution, then high resolution modeling may not be necessary. The use of grid resolution finer than 12 km would generally be more appropriate for areas with a combination of complex meteorology, strong gradients in emissions sources, and/or land-water interfaces in or near the nonattainment area(s)"*

EPA's modeling in support of the SIP disapprovals simulated a national domain using a 12km grid resolution domain wide. While this makes running a national, regional simulation easier from a technical perspective, it neglects the important issue of the complex meteorology and/or land-water interfaces in or near the nonattainment or maintenance monitors of interest. Indeed, EPA's choice of a 12km grid is an arbitrary choice in contravention of its own guidance when modeling Illinois monitors in Cook County because these monitors are at land-water interfaces.

Photochemical modeling along coastlines is complex for two reasons. First, the temperature gradients along land/water interfaces can lead to localized on-shore/off-shore flows; and

secondly, the photochemical model formulation spreads the emissions in a grid cell throughout the full grid volume of the cell.

Figure 1 presents a unique area along Lake Michigan that is challenged by these complex meteorologic issues at land-water interfaces. For the Cook County, Illinois monitor with which Minnesota is linked in this final rule, EPA's published model performance evaluation (MPE) metrics for ozone have been reviewed by Alpine on a day-specific basis.

Figure 1. Lake Michigan shoreline monitors located on land/water interface in Illinois.

Studies indicate that air quality forecast models typically predict large summertime ozone abundances over water relative to land and that meteorology around Lake Michigan is distinctly unique; both shortcomings warrant individualized attention and a finer grid resolution to best explore actual conditions.[9,10,11]

The 3x3 neighborhood of grid cells used in determining the design values of the relative response factor (RRF) at land-water interface monitors extends into the noted water bodies. Under current guidance, the top ten modeled days within this 3x3 matrix are used in determining this RRF for each monitor with any cell identified as 50 percent or more water, except for cells including monitors, which are omitted from the calculations.

Table 1 below provides a list of top 10 days at monitor 170310001 (Alsip/Village Garage), the Cook County monitor in Illinois to which Minnesota is linked, and comparisons of daily modeled

maximum daily average 8-hour ozone concentrations (highlighted in green) and observations on the same date in 2016 (highlighted in blue). These are the dates selected in EPA's modeling to represent the highest modeled days used in estimating future year design values.

As can be seen in Table 1 below, several days selected for RRF calculation have modeled ozone concentrations that fall outside of normally acceptable normalized bias (NBias) boundaries (±15%), here as the result of over (positive bias) predictions compared to observed concentrations on those days. In fact, at the monitor example below, seven of the ten selected days fall outside of the ±15% bias metric (highlighted in orange in the Table) with a maximum normalized bias of 93.60% (observation was 45.25 ppb and modeled concentration was 87.60 ppb; a difference of over 42 ppb).

When these dates are used, EPA's calculation of future year DV is 68.2 ppb (average) and 71.9 ppb (maximum) using the average RRF of 0.9349, identifying this as a maintenance monitor.

	Average	**Maximum**
Modeled 2016 DV (ppb)	73.0	77.0
Average RRF	0.922	0.922
Future 2023 DV (ppb)	67.3	70.9

Table 2. Alternate bias adjusted list of top 10 days at the Alsip/Village Garage monitor (170310001) in Illinois used in RRF and resulting calculated design values (ppb).

As a result of this bias adjusted calculation, the Alsip / Village Garage monitor located in Cook County, Illinois (170310001) has an average RRF of 0.922, resulting in an average 2023 DV of 67.3 ppb and a maximum DV of 70.9 ppb, identifying this monitor as attainment of the 2015 ozone NAAQS.

Under Step 1 of the ozone transport framework established by EPA, this monitor would not be considered as part of the list of receptors in the significant contribution calculation and therefore any linkages from upwind state contributions would be irrelevant.

Since this is the only monitor in which Minnesota is linked as a significant contributor under EPA's modeling, this linkage would be broken, and Minnesota should be removed from the list of contributing states to downwind receptors.

In the Response to Comments document from the rule, EPA attempted to address the bias issue by preparing an analysis at select monitors in the modeling domain. Specifically, EPA notes[12] that,

> *"Even though the EPA disagrees with commenter's assertion to "throw out" specific days at individual monitors for which model performance does not meet the criteria, out of an abundance of caution, the EPA performed a sensitivity analysis for selected receptors in which the projected 2023 DVs and contributions were recalculated after removing individual days that fell outside the Emery et al., criteria for normalized mean bias and/or normalized mean error. The EPA chose receptors in Coastal Connecticut, the Lake Michigan area, Dallas, and Denver for this analysis. The specific receptors included in this sensitivity analysis are Stratford, Connecticut, Chicago/Evanston, Illinois, Dallas/Denton, Texas, and Denver/Rocky Flats, Colorado."* (emphasis added)

While we agree with EPA's technical approach and calculations in their Chicago/Evanston example provided, EPA's selection of the Evanston monitor is questionable as it is the only monitor out of ten in Cook County, Illinois (three which are identified as maintenance) where performance-based recalculation results in higher design values. This is also not the unique, individual monitor to which Minnesota is exclusively linked. Table 3 presents the ten Cook County, Illinois monitors in EPA's modeling results[13].

As presented in Table 2, using bias-adjusted design values for the individual receptor with which Minnesota is linked (170310001), this monitor is calculated to be in attainment of the 2015 ozone NAAQS in 2023. This decrease is also seen in the remaining Cook County monitors that EPA did not consider in its response to comments on the issue.

Table 4. EPA final rule and bias-adjusted future year design values (ppb) of monitors in Cook County, Illinois.

Additionally, the LMOS 2017 study[14] shows that for Lake Michigan coastal monitors the air quality model even at a 4 km resolution does not simulate the proper timing and structure of the land/lake breeze or the inland penetration of elevated ozone concentrations. A review of this LMOS study[15] states "To reproduce the timing and magnitude of the ozone time series at coastal monitors, ozone production over the lake must be correctly simulated; furthermore, details of the lake breeze must be accurate——timing, horizontal extent, and vertical structure." Based on recommendations from the LMOS 2017 study research team, a horizontal resolution of at most 1.3 km is required to reasonably resolve the complex meteorology of the air/water interface for the great lakes and coastal ocean areas. The LMOS 2017 Study researchers believe that a 1.3 km grid spacing will assist in the resolution of the large ozone concentration gradients that often occur along the shoreline as well as the inland penetration of the lake breeze circulation.

As the Alsip / Village Garage example shows, days where modeled ozone was predicted at concentrations differing up to ± 42 ppb are being used to estimate future year ozone concentrations and to make determinations of nonattainment, maintenance, and significant contribution from upwind sources.

Furthermore, to adequately capture the inland penetration of the lake breeze, the LMOS report also cites the need for accurate Lake Michigan water temperatures and correct model physics options. EPA's use of the Pleim-Xiu Land Service Model (LSM) does not adequately capture the lake breeze inland penetration. A review of wind vector observations (from the Meteorological Assimilation Data Ingest System (MADIS) network) compared to modeled wind vectors on RRF and significantly contributing days at nonattainment monitors highlights the differences in wind direction and speed during many hours of these predicted high ozone episodes.

On many days with relatively simple meteorology, EPA-developed wind fields using the Weather Research and Forecasting (WRF) Model agree with the MADIS observed winds. However, the modeled winds have strong disagreement with the observed meteorology on June 15, July 7, July 27 and August 4, 2016, the four days when the CAMx model predicted the highest ozone concentrations and are thus used in estimating RRFs and future year ozone design values. The following presents an example on August 4, 2016, a day within the top ten highest model estimated MDA8 ozone concentrations at the Alsip / Village Garage monitor.

---

[15] Stanier, C. O., & et al. (2021, November). Overview of the Lake Michigan Ozone Study 2017. BAMS, 19.

In Figure 2 below, the black wind vectors are the wind fields used in the CAMx model. For clarity only every third grid cell is presented. The red vectors are the hourly observed wind vectors from the MADIS archive. The hourly results from 1300 CDT through 1600 CDT are presented in these Figures. The observations clearly show a broad persistent land to lake flow along the western shoreline while the model shows a persistent lake to land flow in this same region during this same period. For this timeframe, when the model is estimating the highest ozone for the ozone season at this receptor, the model has the winds flowing from the lake to the shore while the observations are winds flowing from the shore to the lake.

Figure 2 demonstrates that observed winds (red arrows) are seen moving from land to lake along the western shoreline of Lake Michigan, typically associated with clearing events and lower ozone levels in areas in and around Chicago. In contrast, the model (black arrows) shows a lake to land flow, typically associated with higher model predicted ozone concentrations due to the higher reactive photochemistry over water bodies.

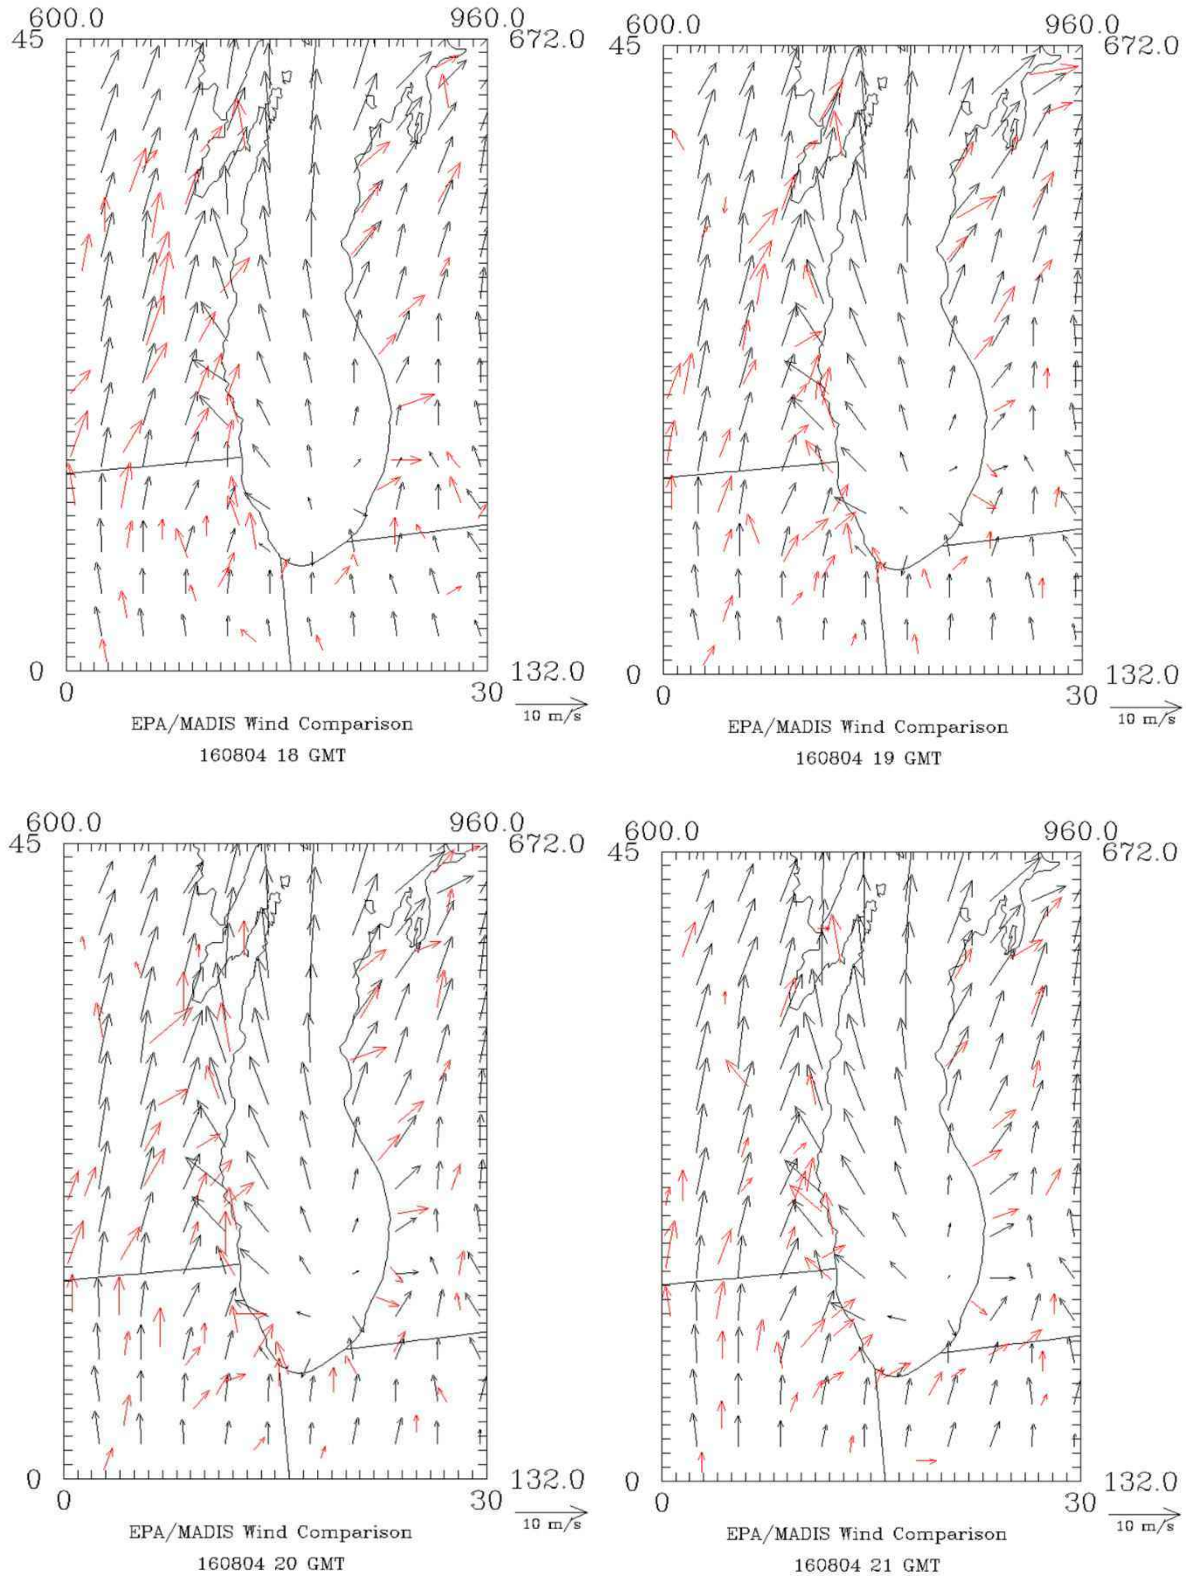

Figure 2. Model estimated (black) and observed (red) winds in the Lake Michigan area at 1300 CDT (top left), 1400 CDT (top right), 1500 CDT (bottom left), and 1600 CDT (bottom right) on August 4, 2016.

These large differences in observed and modeled wind directions are altering the concentration calculations as well as the source/receptor relationships (e.g., determining which sources are "upwind") of the Illinois monitors. As a result, the model cannot accurately reproduce the chemical processes involved with ozone formation. The erroneous modeled meteorological conditions fundamentally change the ozone formation chemistry and modeled source contributions as the chemical transport model predicts more emissions coming from the Chicago urban area than likely the case consistent with the observed wind fields.

When the model is having difficulty resolving fundamental flow patterns in this region with this grid size resolution, EPA needs to reconsider the merit of using the model with this configuration to determine nonattainment status in Step 1 as well as linked significant contributors at receptors in this region under Step 2. For these reasons, EPA must consider finer grid resolution modeling over the Lake Michigan domain to adequately capture ozone formation and significant contribution at receptors located on complex land-water interfaces because model evaluation shows that the model fails to adequately characterize ozone production at these monitors.

Absent a wholesale revision of EPA's modeling protocol, it is our opinion that EPA's use of modeling with poor performance at critical monitors amounts to an unreliable result when used to establish nonattainment or maintenance monitors under Step 1 or linkages under Step 2 of the 4-step framework. Should more refined modeling be undertaken to review the ozone formation potential at monitors located in these land-water interfaces, results may show that these monitors demonstrate modeled attainment and/or remove significant contribution linkages from upwind states.

3. EPA is obligated to address VOC emissions as a critical factor that is influencing ozone nonattainment/maintenance monitors in Illinois

EPA's modeling fails to account for VOC-limited conditions in the Lake Michigan region. Recent information supports the conclusion that VOC-limited conditions in the regional are much more significant that EPA has assumed. This results in EPA's analysis overemphasizing upwind NOx contributions from Minnesota on ozone values at the Alsip/Village Garage monitor and an underemphasis on local VOC contributions, which can be more effectively used to control ozone.

In addition to grid size resolution and complex meteorology issues, modeling performed by EPA[16] and the LMOS 2017 study both showed a negative bias in predicted ozone concentrations in the Lake Michigan region. LMOS 2017 study researchers have experimented with increasing

[16] EPA-HQ-OAR-2021-0668-0099

anthropogenic VOC emissions and decreasing anthropogenic NOx emissions. These emission changes improved air quality model performance reducing the negative bias. VOC speciation and spatio-temporal release patterns should also be reviewed. This evaluation by the LMOS 2017 research scientists indicates there are significant errors in the quantity and speciation of the VOC/NOx emissions used in the EPA's air quality modeling platform to characterize state contribution to ozone in Step 2 of EPA's analyses linking these states to critical nonattainment monitors.

Several downwind nonattainment monitors in urban areas around Lake Michigan recently have been shown to be largely unresponsive to ozone reduction strategies consisting of regional interstate NOx control and that high ozone days in the region were predominantly VOC-limited in nature. This was demonstrated in multiple ozone episodes extensively evaluated in the Lake Michigan Air Directors Consortium (LADCO) Lake Michigan Ozone Study (LMOS) 2017 study[17] where ozone precursor measurements indicated relative increases in VOC concentrations with increases in ozone and where biogenic VOC increases outpaced those of anthropogenic VOC.

In contrast to the peer reviewed research resulting from the 2017 LMOS data collection effort, EPA recently documented its support for additional NOx controls in stating that its "review of the portion of the ozone contribution attributable to anthropogenic NOX emissions versus VOC emissions from each linked upwind state leads the Agency to conclude that the vast majority of the downwind air quality areas addressed by the proposed rule under are primarily NOX-limited, rather than VOC-limited."[18] However, the current situation is that the modeling as conducted does not accurately characterize ozone levels on high ozone days, underpredicting by 10 + ppb, which is a huge error. Other studies indicate that, to better match actual conditions, the model needs less NOx and higher windspeeds at lower levels. The model is therefore demonstrating that less NOx means more ozone and higher ozone concentrations. That further means that, proportionally, the attribution of ozone to out of state NOx predicts a higher impact than is occurring.

The modeled VOC and NOx emission tracers in EPA's Anthropogenic Precursor Culpability Assessment (APCA) modeling can give a general indication of the VOC/NOx sensitivity, but EPA assigning definitive numerical values to that sensitivity provides inaccurate projections, especially using APCA that is known to have a bias toward attributing ozone to NOx emitting anthropogenic sources under VOC sensitive conditions. As documented in the CAMx v 7.10 User's Guide[19], "when ozone formation is due to biogenic VOC and anthropogenic NOx under

[17] https://www.ladco.org/wpcontent/
uploads/Research/LMOS2017/LMOS_LADCO_report_revision_apr2019_final.pdf
[18] 87 Fed. Reg. 20,076
[19] https://camx-wp.azurewebsites.net/Files/CAMxUsersGuide_v7.10.pdf, page 177.

VOC-limited conditions (a situation where OSAT would attribute ozone production to biogenic VOC), APCA attributes ozone production to the anthropogenic NOx present. Using APCA instead of OSAT results in more ozone formation attributed to anthropogenic NOx sources and less ozone formation attributed to biogenic VOC sources." Here, it is believed that as applied in this case (with biogenic emissions as an uncontrollable source group), EPA has overestimated the efficacy of NOx controls on these receptors as modeled results have a bias toward attributing more ozone formed to NOx emissions than VOC emissions.

Furthermore, an independent review of EPA's own NOx and VOC contributions challenges the Agency's statement that "[o]ur analysis of the ozone contribution from upwind states subject to regulation under this proposed rule demonstrates that the vast majority of the downwind air quality areas are NOX-limited, rather than VOC-limited."[20] This statement is based on all anthropogenic NOx and VOC emissions from all upwind states and is defined as having NOx emissions contribute to 80% or more of the ozone concentrations modeled at each receptor[21].

EPA further goes on to state that "[t]his review of the portion of the ozone contribution attributable to anthropogenic NOX emissions versus VOC emissions from each linked upwind state leads the Agency to conclude that the vast majority of the downwind air quality areas addressed by the proposed rule under are primarily NOX-limited, rather than VOC-limited."[22]

Alpine's review of EPA's modeled NOx and VOC contributions, by upwind state, focusing on the future year modeled days used in each receptor's Step 2 linkage calculation provides a slightly different picture for monitors around Lake Michigan. As demonstrated in Table 5, of the top future year modeled days impacting significant contribution calculations at the Cook County, Illinois monitor with which Minnesota is linked, more than half of the days are shown to have NOx emission contributions from Illinois below the 80% threshold noted by EPA in determining NOx-limited regions. This is an indicator that on those days, and from anthropogenic sources from those states, VOC controls may demonstrate meaningful impact on ozone concentration reductions at this receptor.

Researchers at the University of Maryland (UMD) have also found in a study of chemical transport model results that by 2023, model predictions of ozone formed under VOC-limited conditions are substantial near the Long Island Sound and the Great Lakes. In a recent presentation[23], they document a source apportionment simulation, conducted with CAMx/APCA on future-year 2023 to determine the major contributing sources and states to air

[20] 87 Fed. Reg. 20053

[23] https://www.cmascenter.org/conference/2021/slides/allen-northeast-ambient-ozone-2021.pdf

quality within non-attainment areas. Their findings indicate that ozone production under VOC-limited conditions is important at coastal locations near Long Island Sound and the Great Lakes.

Table 5. Modeled ozone contributions to Cook, Illinois monitor (170310001) by percent of emissions from anthropogenic NOx (O3N) compared to emissions from anthropogenic NOx and VOC (O3). Yellow cells indicate contributions of anthropogenic VOC emissions greater than EPA identified "NOx-limited" areas.

Figure 3 presents UMD's findings for model predictions of ozone formation under NOx limited conditions excluding the influence of boundary and initial conditions from the modeling input. As can be seen in these figures, regions around Lake Michigan demonstrate a significantly higher percentage of ozone formed by VOC (blue in color) compared to NOx than most of the eastern US. This observation is seen both on modeled days greater than 60 ppb and on the top ten days of the ozone season (days used in RRF and significant contribution calculations).

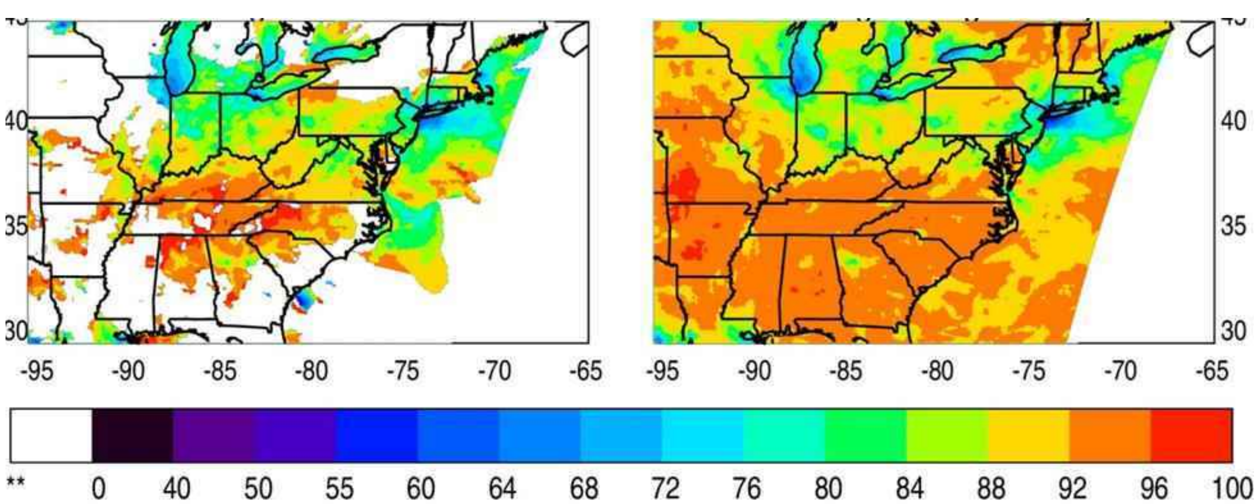

Figure 3. Percent of ozone formed under NOx-limited conditions excluding boundary and initial conditions on all days of MDA8 ozone > 60 ppb (left) and on top ten modeled days (right).

It is also noted that these estimates are a very conservatively high estimate of NOx limited conditions for these coastal areas. In addition to the previous comments highlighting that APCA is known to have a bias toward attributing ozone to NOx emitting anthropogenic sources under VOC sensitive conditions, the UMD analysis footnotes that the APCA run used to generate the results presented in Figure 3 suggests that model configuration led to an underestimation of the contribution of anthropogenic sources to ozone formation, especially during periods of VOC limited chemistry, and as is seen in Figure 3, in the Cook County, Illinois area.

As a result of these findings, EPA is obligated to address the concern that VOC emissions are a factor that is influencing ozone nonattainment and maintenance monitors in Illinois and elsewhere and that EPA determination of ozone nonattainment or maintenance in these areas may be inappropriate for significant contribution and upwind state linkage calculation. It is also our opinion that after review of VOC contribution and limited ozone reduction potential in Chicago and other noted areas, EPA may find that emission reduction plans may fail to justify regional NOx rules for monitors within these transitional and VOC-limited domains.

B. U.S. EPA's revisions to its modeling approach since MPCA's SIP submittal were ancillary.

EPA failed to give appropriate recognition of the merit of the MPCA SIP submitted on October 1, 2018, meeting the statutory deadline for submittal of interstate transport SIPs for the 2015 ozone NAAQS. The submission utilized both EPA modeling released with the March 2018 memorandum and LADCO modeling results previously mentioned. Minnesota followed the 4-step interstate transport framework and used an analytic year of 2023 to describe Minnesota's lack of contributions to out of state receptors and assess emission reduction considerations.

Under the CAA, on April 1, 2019, MPCA's SIP was deemed to be complete since EPA did not act within the 6 months from the date the SIP was submitted. April 1, 2020, 12 months after the completeness date, was the deadline for EPA to have acted on the MPCA SIP submission. Upon this deadline a full, partial or conditional approval was required by CAA Section 110(k)(2), (3), or (4).[24] In this regard, EPA failed to complete its non-discretionary duty to have reviewed and acted upon the MN SIP by April 1, 2020.

It wasn't until February 22, 2022, three years and four months after submittal, that EPA finally assessed the Minnesota SIP submittal and proposed disapproval of the SIP[25] as follows: "Based on EPA's evaluation of Minnesota's SIP submission and after consideration of updated EPA modeling using the 2016-based emissions modeling platform, EPA is proposing to find that the portion of Minnesota's October 1, 2018 SIP submission addressing CAA section 110(a)(2)(D)(i)(I) does not meet the state's interstate transport obligations for 2015 ozone NAAQS, because it fails to contain the necessary provisions to eliminate emissions that will contribute significantly to nonattainment or interfere with maintenance of the NAAQS in any other state."

The EPA reiterated this assessment and issued a partial approval on February 13, 2023, in their final rule stating that "Although the EPA acknowledges that Minnesota's Step 3 analysis was insufficient in part because the State assumed it was not linked at Step 2, this is ultimately inadequate to support a conclusion that the State's sources do not interfere with maintenance of the 2015 ozone NAAQS in other states in light of more recent air quality analysis."[26]

[24] **Deadline for Action**. – Pursuant to the CAA Section 110(k)(1)(B) "Within 12 months of a determination by the Administrator (or a determination deemed by operation of law) under paragraph (1) that a State has submitted a plan or plan revision (or, in the Administrator's discretion, part thereof) that meets the minimum criteria established pursuant to paragraph (1), if applicable (or, if those criteria are not applicable, within 12 months of submission of the plan or revision), the Administrator shall act on the submission in accordance with paragraph (3)."

[25] 87 Fed. Reg. 9838

[26] 88 Fed. Reg. 9357

1. EPA's Failure to Act

MPCA has been disadvantaged by EPA's delay in acting to approve or disapprove its 2015 Good Neighbor SIP, which was submitted to EPA on October 1, 2018. EPA published its proposed disapproval on February 22, 2022, and relied in part on newer, updated modeling performed by the EPA which was not available when MPCA submitted its revised SIP. On February 13, 2023, EPA published its final disapproval and again relied on even newer, updated modeling only released with the rule.

By delaying its final decision on Minnesota's submittal for nearly four and a half years, EPA moved the goal post for Minnesota—an act the DC Circuit rebuked in New York v. EPA, 964 F.3d 1214, 1223 (D.C. Cir. 2020). If EPA were to review and approve or disapprove SIPs within the timeframes required by the CAA, EPA would have conducted its review based on the same modeling and data that was available at the time the SIP was submitted and that has been documented in the sections above. EPA offers no indication that additional material information was available to EPA on April 1, 2020, when agency action on the Minnesota SIP was required that could justify disapproval of the Minnesota SIP.

Further, the updated modeling that EPA now offers to support a SIP review has not been adequately available to be reviewed, analyzed, and commented on in advance of any final decision on the subject SIP disapproval.

2. EPA has not developed any official guidance for states to follow in submitting a Good Neighbor SIP

The Good Neighbor SIP has been a required SIP element since the implementation of the 1997 8- hour ozone standard. In the intervening years, EPA has issued no official guidance for states to use in developing an approvable Good Neighbor SIP. It is unclear what standard or criteria EPA uses to determine approvability.

In its only direction on the subject, EPA released three 2018 memos that included modeling and discussion on potential flexibilities in approaches that could be used by states in developing their Good Neighbor SIPs. However, EPA has now disapproved MPCA's SIP which was based on EPA's own modeling results from the memo because it "does not meet the state's interstate transport obligations for 2015 ozone NAAQS, because it fails to contain the necessary provisions to eliminate emissions that will contribute significantly to nonattainment or interfere with maintenance of the NAAQS in any other state."[27]

[27] 87 FR 9869

From the memos, the only concrete guidance states have been provided is the four-step framework. Applied appropriately in the MPCA SIP, this framework demonstrated that Minnesota was not significantly linked to any downwind nonattainment or maintenance monitor. Since MPCA used EPA's own modeling and four-step approach to prepare its SIP, the SIP was approvable at the time submitted and was approvable when EPA was required to act on the SIP on April 1, 2020.

3. EPA's ever-changing list of nonattainment and maintenance monitors moves the target for Minnesota without offering any basis to reject MPCA's original analysis.

As detailed earlier, MPCA's air quality projections based on the ozone modeling conducted by LADCO in October 2018 was corroborated by EPA's own contribution modeling released with the March 2018 flexibilities memorandum and that showed that Minnesota was not linked to any monitor designated as nonattainment or maintenance for the 2015 ozone NAAQS in 2023. In those two modeling studies, the Cook County, Illinois monitor now linked to Minnesota was calculated to be in attainment for the 2015 ozone NAAQS.

Table 6 provides the average and maximum projected design values from the LADCO modeling that supported the original MPCA iSIP and March 2018 EPA memo modeling for this monitor demonstrating modeled attainment at this location.

			LADCO Modeling		EPA March 2018 Memo	
AQS Site ID	**State**	**County**	**2023 Average DV**	**2023 Maximum DV**	**2023 Average DV**	**2023 Maximum DV**
170310001	Illinois	Cook	62.8	64.6	63.2	64.9

Table 6. LADCO and EPA 2023 ozone design values (ppb) for Minnesota linked Cook County, Illinois monitor from original MPCA SIP and March 2018 EPA memo modeling results.

EPA's proposed disapproval mentions new modeling conducted by EPA in the interim where this Illinois monitor is ultimately identified as a maintenance monitor. Table 7 below provides the average and maximum projected design values from these studies and from the final SIP disapproval for this monitor.

In the proposed SIP disapproval, EPA cites the "results of a prior round of 2023 modeling using the 2016v1 emissions platform which became available to the public in the fall of 2020 in the Revised CSAPR Update." [28] In this Revised CSAPR Update modeling, developed for use with the 2008 ozone NAAQS analyses, monitor 170310001 is identified as a maintenance monitor in

[28] Footnote 94, 87 FR 9869

EPA's results. In EPA's results published in the proposed SIP disapproval[29] and in the final SIP disapproval[30], EPA continued to identify this monitor as a maintenance monitor.

AQS Site ID	EPA Revised CSAPR Update		EPA Proposed SIP Disapproval		EPA Final SIP Disapproval	
	2023 Ave DV	**2023 Max DV**	**2023 Ave DV**	**2023 Max DV**	**2023 Ave DV**	**2023 Max DV**
170310001	68.4	72.2	69.6	73.4	68.2	71.9

Table 7. EPA 2023 ozone design values (ppb) for Cook County, Illinois monitor from EPA cited modeling results in proposed and final Minnesota SIP disapproval.

In our opinion, EPA should always rely on the best available modeling at the time that an analysis is conducted and results, whether in a SIP or other, are developed and submitted. In this case, EPA has failed to follow this process and instead continued to move the target and objectives for states that, in Minnesota's case, for over four years and four months had been waiting for a review of their "best available data and analysis".

4. Alternative 1 ppb significance threshold

Neither the LADCO modeling nor EPA modeling released with the March 2018 memorandum indicated that Minnesota would contribute over 1% of the NAAQS to any nonattainment or maintenance monitor in 2023. As a result, Minnesota did not think it necessary to consider using a 1 ppb threshold for significant contribution to downwind receptors, which EPA guidance offered as an option to States.

In the SIP disapproval, EPA further elaborates that following their receipt and review of forty-nine good neighbor SIPs for the 2015 ozone NAAQS, their experience was that no state relying on a 1 ppb threshold provided sufficient information and technical support to justify that an alternative threshold was reasonable[31]. EPA does not indicate how many of the reviewed SIPs used a 1 ppb threshold nor do they indicate on how many state SIPs they provided feedback, if any. They go on to state that this alternate 1 ppb threshold may also be politically inconsistent and impractical under the CAA[32].

As EPA not only failed to provide any feedback to Minnesota on its original October 1, 2018 SIP submittal until the February 22, 2022 proposed SIP disapproval, EPA has also failed to honor its March 2018 guidance[33] which was identified to specifically "*provide analytical information*

[29] Table 5, 87 FR 9868
[30] Table III.B-2, 88 FR 9351
[31] 87 FR 9843
[32] Footnote 33, 87 FR 9843
[33] https://www.epa.gov/sites/default/files/2018-03/documents/transport_memo_03_27_18_1.pdf

regarding the degree to which certain air quality threshold amounts capture the collective amount of upwind contribution from upwind states to downwind receptors or the 2015 ozone NAAQS. It also interprets that information to make recommendation about what thresholds may be appropriate for use in state implementation plan (SIP) revisions addressing the good neighbor provision for that NAAQS."

Minnesota has been denied the opportunity to correct the model inputs that EPA uses as the basis for SIP Disapproval at the 1% threshold and denied the opportunity to update its SIP to take advantage of the 1 ppb threshold that EPA offers States an opportunity to justify in its guidance. While EPA continues to regenerate results based on updated emission modeling platforms and other associated information, states have been omitted from the process, denying them the chance to review updated information and to provide revisions to their SIPs to address those updates.

It is important to note that under all of EPA's cited modeling results, Minnesota contributes under the 1 ppb permitted to be considered from EPA's March 2018 guidance. Table 8 below shows that under none of EPA's four modeling platforms does Minnesota contribute over the 1 ppb threshold to the Cook County monitor.

			Minnesota Contribution (ppb) in 2023			
AQS Site ID	**State**	**County**	**EPA March 2018 Memo**	**EPA Revised CSAPR Update**	**EPA Proposed SIP Disapproval**	**EPA Final SIP Disapproval**
170310001	Illinois	Cook	0.76	0.79	0.97	0.85

Table 8. Minnesota contribution to Cook County, Illinois 2023 ozone design values from documented modeling platforms.

EPA's 2018 flexibility memos, including the opportunity for states to make recommendations to support alternate thresholds for significant contribution, remains an important tool for addressing unique State circumstances in developing their good neighbor SIPs. Disapproving the Minnesota SIP without affording the State an opportunity to utilize this flexibility is unreasonable and should be reconsidered.

C. The Minnesota Pollution Control Agency's state implementation plan revision was approvable based on the state of the science at the time it was submitted to U.S. EPA.

1. Introduction

On October 1, 2018, the Minnesota Pollution Control Agency, after review and comment by EPA Region 5 staff, submitted to the U.S. Environmental Protection Agency a request for revision of Minnesota's State Implementation Plan[34].

The proposed SIP revision addressed Minnesota's responsibilities relating to the "Infrastructure" SIP (iSIP) requirements of sections 110(a)(l) and 110(a)(2) of the Clean Air Act (CAA), as they pertain to the National Ambient Air Quality Standard (NAAQS) for ozone, promulgated in 2015. The CAA requires states to submit an iSIP within three years of the EPA's issuance of a new NAAQS to demonstrate their continued ability to implement, maintain, and enforce the federal standards. The iSIP outlined the statutes, rules, and programs that enable Minnesota to ensure attainment of the 2015 ozone NAAQS. These statutes, rules, and programs had previously been reviewed and approved into Minnesota's iSIP, and the materials included with the iSIP demonstrate that the MPCA did not have further obligations under the iSIP requirements.

The MPCA submission utilized both EPA modeling released with a March 2018 flexibilities memorandum[35] and Lake Michigan Air Directors Consortium (LADCO) modeling results[36]. Minnesota followed the 4-step interstate transport framework and used an analytic year of 2023 to describe Minnesota's lack of contributions to out of state receptors and assess emission reduction considerations.

In this document we discuss both the technical and legal validity of MPCA's SIP and EPA's obligation to approve the SIP.

EPA's and LADCO's model projections, along with continuing decreases in the emissions and monitored levels of ozone precursors in Minnesota (nitrogen dioxide and volatile organic compounds), demonstrated that no additional controls or emissions limits were necessary to

[34] EPA-R05-OAR-2018-0689-0003
[35] https://www.epa.gov/interstate-air-pollution-transport/memo-and-supplemental-information-regarding-interstate-transport
[36] https://www.ladco.org/wp-content/uploads/Documents/Reports/TSDs/O3/LADCO_2015O3iSIP_TSD_13Aug2018.pdf

fulfill Minnesota's responsibilities under the good neighbor provisions for the 2015 ozone NAAQS.

On February 13, 2023, almost four and a half years after the original SIP submittal, EPA finalized a rule in connection with the Air Plan Disapprovals; Interstate Transport Requirements for the 2015 8-Hour Ozone National Ambient Air Quality Standards[37].

EPA notes in this final rule, that these disapprovals would not start a mandatory sanctions clock but rather would establish a 2-year deadline for EPA to promulgate a Federal Implementation Plan (FIP), unless EPA were to approve a subsequent SIP submittal that meets CAA requirements. EPA originally proposed a FIP to be finalized December 15, 2022, in complete disregard for the 2-year period allowed by the CAA for responding to any such SIP disapprovals[38]. This FIP[39] was signed by the Administrator on March 15, 2023, and is still awaiting publication in the Federal Register.

In 2018 EPA issued flexibility guidance for states to follow in development of 2015 ozone standard NAAQS God Neighbor SIPs (GNS). We specifically question how EPA's late disapproval contradicts this guidance.

2. MPCA's Modeling Approach

The modeling performed to support the SIP was performed by LADCO and except for the 2023 projected EGU emissions, was identical to the "EN" platform developed by EPA and followed EPA guidance[40] in preparation of technical material for SIP and SIP-related modeling. The EN platform was used by EPA in its March 2018 flexibility memorandum so that "[s]tates can use these data to develop their implementation plans to assure that emissions within their jurisdictions do not contribute significantly to nonattainment or interfere with maintenance of the 2015 ozone standards in other states."

In our opinion, this platform was technically credible, and a SIP developed from these data should have been approvable by EPA at the time of submission in October 2018. The following sections present our opinions on specific technical aspects of MPCA modeling.

Base Year

The base year for the MPCA modeling was 2011. 2011 was selected because of data availability and because EPA[41] had noted that 2011 meteorology in the Eastern U.S., including the upper Midwest, was warmer and drier that the climatic norm and represented typical conditions conducive to high observed ozone concentrations in the Midwest and Northeast U.S. It is Alpine's opinion that 2011 was an appropriate modeling year.

Model and Data Selection

This section introduces the models and data sources used in the MPCA. The selection methodology followed EPA's guidance for ozone regulatory modeling[42],[43],[44]. EPA's 2018 modeling guidance[45] lists several criteria for model selection that are paraphrased as follows (pp. 24-27):

- It should not be proprietary;
- It should have received a scientific peer review;
- It should be demonstrated to be applicable to the problem on a theoretical basis;
- It should be used with data bases which are available and adequate to support its application;
- It should be shown to have performed well in past modeling applications;
- It should be applied consistently with an established protocol on methods and procedures;
- It should have a user's guide and technical description;
- The availability of advanced features (e.g., probing tools or science algorithms) is desirable; and

- When other criteria are satisfied, resource considerations may be important and are a legitimate concern.

It is Alpine's opinion that the models chosen for the MPCA modeling met these criteria and were appropriate for use in the SIP.

Meteorological Modeling

The Weather Research and Forecasting (WRF) Model is a mesoscale numerical weather prediction system designed to serve both operational forecasting and atmospheric research needs[46],[47],[48]. The Advanced Research WRF (ARW) version of WRF was used in the MPCA modeling study. It features multiple dynamical cores, a 3-dimensional variational (3DVAR) data assimilation system, and a software architecture allowing for computational parallelism and system extensibility. WRF is suitable for a broad spectrum of applications across scales ranging from meters to thousands of kilometers. The effort to develop WRF has been a collaborative partnership, principally among the National Center for Atmospheric Research (NCAR), the National Oceanic and Atmospheric Administration (NOAA), the National Centers for Environmental Prediction (NCEP) and the Forecast Systems Laboratory (FSL), the Air Force Weather Agency (AFWA), the Naval Research Laboratory, the University of Oklahoma, and the Federal Aviation Administration (FAA). WRF allows researchers the ability to conduct simulations reflecting either real data or idealized configurations. WRF provides operational forecasting a model that is flexible and efficient computationally, while offering the advances in physics, numerics, and data assimilation contributed by the research community.

WRF is publicly available, has full documentation and has demonstrated success in simulating meteorological conditions in the Upper Midwest.

MPCA used the U.S. EPA 2011 WRF data for this study[49]. The U.S. EPA used version 3.4 of the WRF model, initialized with the 12-km North American Model (NAM) from the National Climatic Data Center (NCDC) to simulate 2011 meteorology. Complete details of the WRF simulation, including the input data, physics options, and four-dimensional data assimilation (FDDA) configuration are detailed in the U.S. EPA 2008 Transport Modeling technical support document[50]. U.S. EPA prepared the WRF data for input to CAMx with version 4.3 of the WRFCAMx software.

It is Alpine's opinion that the U.S. EPA WRF 3.4 meteorological modeling was appropriate for use in the MPCA SIP.

Initial and Boundary Conditions

MPCA used 2011 initial and boundary conditions for CAMx generated by the U.S. EPA from the GEOS-Chem Global Chemical Transport Model[51]. EPA generated hourly, one-way nested boundary conditions (i.e., global-scale to regional-scale) from a 2011 2.0 degree x 2.5 degree GEOS-Chem simulation. Following the convention of the U.S. EPA O3 transport modeling, year 2011 GEOS-Chem boundary conditions were used by LADCO for modeling 2023 air quality with CAMx.

It is Alpine's opinion that the U.S. EPA GEOS-Chem derived initial and boundary conditions were appropriate for use in the MPCA SIP.

Emissions

The 2023 emissions data for the MPCA SIP were based on the U.S. EPA 2011v6.3 ("EN") emissions modeling platform[52]. U.S. EPA generated this platform for their final assessment of Interstate Transport for the 2008 O3 NAAQS. Updates from earlier 2011-based emissions modeling platforms included a new engineering approach for forecasting emissions from Electricity Generating Units (EGUs). LADCO replaced the EGU emissions in the U.S. EPA EN

[52] US EPA. 2017. Technical Support Document: Additional Updates to Emissions Inventories for the Version 6.3 Emissions Modeling Platform for the Year 2023. Research Triangle Park, NC. https://www.epa.gov/sites/production/files/2017-11/documents/2011v6.3_2023en_update_emismod_tsd_oct2017.pdf

platform with 2023 EGU forecasts estimated with the ERTAC EGU Tool version 2.7[53]. ERTAC EGU 2.7 integrates state-reported information on EGU operations and forecasts as of May 2017. The MPCA believes "power sector emissions forecasts must address economic factors, preserve system reliability, and include controls or emission reduction measures justified through some legal framework. It is our understanding that the engineering analysis used by EPA to project EGU emissions to 2023 (version EN of the modeling platform) does not comply with these key requirements. The ERTAC estimates incorporate the key requirements."[54]

In March 2018 U.S. EPA released it flexibilities memo that described a series of flexibilities that states could consider in developing Good Neighbor SIPs for the 2015 ozone NAAQS. The "[u]se of alternative power sector modeling consistent with EPA's emissions inventory guidance" is presented in the Analytics section of EPA's March 2018 memo as a flexibility to consider in preparing a Good Neighbor SIP. This flexibility supports LADCO's use of the ERTAC EGU model for projecting EGU emissions to 2023. MPCA considers the emissions projections from ERTAC EGU to be more representative of the sources in the Midwest and Northeast than the approach used by U.S. EPA in their 2023 EN modeling platform. As ERTAC EGU is developed in collaboration between regional and state air planning agencies, it includes algorithms and data that have been reviewed by many of the states impacted by interstate O3 transport in the Midwest and Eastern U.S.

Preparation of the emissions data to support photochemical models is a very complicated process that entails the use of a number of different "sub-models" to prepare different emission segments.

Sparse Matrix Operator Kernel Emissions (SMOKE)

The Sparse Matrix Operator Kernel Emissions (SMOKE) is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, non-road, area, point, fire and biogenic emission sources for PGMs[55],[56]. As with most "emissions models," SMOKE is principally an emission processing system and not a true emissions modeling system in which emissions estimates are simulated from "first principles." This means that, except for mobile and biogenic sources, its purpose is to provide an efficient, modern tool for converting an existing base emissions inventory data that is typically at the county or point source level into

[53] http://www.marama.org/2013-ertac-egu-forecasting-tool-documentation

[54] EPA-R05-OAR-2018-0689-0003

[55] Coats, C.J. 1995. Sparse Matrix Operator Kernel Emissions (SMOKE) Modeling System, MCNC Environmental Programs, Research Triangle Park, NC.

[56] UNC. 2018. SMOKE v4.6 User's Manuel. University of North Carolina at Chapel Hill, Institute for the Environment. Chapel Hill, North Carolina. September 24. (https://www.cmascenter.org/smoke/documentation/4.6/manual_smokev46.pdf).

the hourly gridded speciated formatted emission files required by a Photochemical Grid Model (PGM), like CAMx. SMOKE was used to prepare emission inputs for non-road mobile, non-point (area) and point sources. SMOKE performs three main function to convert emissions to the hourly gridded emission inputs for a PGM: (1) spatial allocation, spatial allocates county-level emissions to the PGM model grid cells typically using a surrogate distribution (e.g., population); (2) temporal allocation, allocates annual emissions to time of year (e.g., monthly or seasonally) and day-of-week (typically weekday, Saturday and Sunday); and (3) chemical speciation, maps the emissions to the species in the chemical mechanism used by the photochemical grid model, most important for VOC and $PM_{2.5}$ emissions.

The primary emissions modeling tool used to create the air quality model-ready emissions was the SMOKE modeling system version 3.7 which was used to create emissions files for a 12-km national grid "12US2" that includes all of the contiguous states.

It is Alpine's opinion that the SMOKE emissions model together with the other EPA emissions was appropriate for use in the MPCA SIP.

Motor Vehicle Emissions Simulator (MOVES)

The motor vehicle emissions were prepared by U.S. EPA using the MOVES 2014a emissions model[57],[58],[59]. MOVES 2014a was the most up to date released motor vehicle emissions processor at the time of the MPCA SIP submission and it is Alpine's opinion that the U.S. EPA MOVES 2014a emissions were appropriate for use in the MPCA SIP.

Eastern Regional Technical Advisory Committee EGU Model

The Eastern Regional Technical Advisory Committee (ERTAC) EGU model for growth was developed around activity pattern matching algorithms designed to provide hourly EGU emissions data for air quality planning. The original goal of the model was to create low-cost software that air quality planning agencies could use for developing EGU emissions projections. States needed a transparent model that was numerically stable and did not produce dramatic changes to the emissions forecasts with small changes in inputs. A key feature of the model

[57] EPA. 2014a. Motor Vehicle Emissions Simulator (MOVES) – User Guide for MOVES2014. Assessment and Standards Division, Office of Transportation and Air Quality, U.S. Environmental Protection Agency. (EPA-420-B-14-055). July. (http://www.epa.gov/oms/models/moves/documents/420b14055.pdf).

[58] EPA. 2014b. Motor Vehicle Emissions Simulator (MOVES) –MOVES2014 User Interface Manual. Assessment and Standards Division, Office of Transportation and Air Quality, U.S. Environmental Protection Agency. (EPA-420-B-14-067). July. (http://www.epa.gov/oms/models/moves/documents/420b14057.pdf).

[59] EPA. 2014b. Motor Vehicle Emissions Simulator (MOVES) –MOVES2014 User Interface Manual. Assessment and Standards Division, Office of Transportation and Air Quality, U.S. Environmental Protection Agency. (EPA-420-B-14-067). July. (http://www.epa.gov/oms/models/moves/documents/420b14057.pdf).

includes data transparency; all of the inputs to the model are publicly available. The code is also operationally transparent and includes extensive documentation, open-source code, and a diverse user community to support new users of the software.

Operation of the model is straightforward given the complexity of the projection calculations and inputs. The model imports base year Continuous Emissions Monitoring (CEM) data from U.S. EPA and sorts the data from the peak to the lowest generation hour. It applies hour specific growth rates that include peak and off-peak rates. The model then balances the system for all units and hours that exceed physical or regulatory limits. ERTAC EGU applies future year controls to the emissions estimates and tests for reserve capacity, generates quality assurance reports, and converts the outputs to SMOKE ready modeling files.

ERTAC EGU has distinct advantages over other growth methodologies because it can generate hourly future year estimates which are key to understanding ozone episodes. The model does not shutdown or mothball existing units because economics algorithms suggest they are not economically viable. Additionally, alternate control scenarios are easy to simulate with the model. Full documentation for the ERTAC Emissions model and 2.7 simulations are available through the MARAMA website[60].

Differences between the EPA and ERTAC EGU emissions forecasts arise from alternative forecast algorithms and from the data used to inform the model predictions. The U.S. EPA EGU forecast used in the 2023 EN modeling used CEM data available through the end of 2016 and comments from states and stakeholders received through April 17, 2017[61]. ERTAC EGU 2.7 used CEM data from 2011 and state-reported changes to EGUs through May 2017. The ERTAC EGU 2.7 emissions used for the modeling represented the best available information on EGU forecasts for the Midwest and Eastern U.S. available during Spring-early Summer 2018.

The “consideration of state-specific information in identifying sources [e.g., electric generating units (EGUs) and non-EGUs] and controls” is one of the potential approaches in EPA’s March 2018 flexibilities memorandum. The use of the ERTAC EGU tool falls squarely within the parameters of this documented flexibility and it is Alpine’s opinion that MPCA’s used of EGU emission projections from this model were appropriate in the MPCA SIP.

Memorandum: Supplemental Information on the Interstate Transport SIP Submissions for the 2008 Ozone NAAQS under Clean Air Act Section 110(a)(2)(D)(i)(I), Research Triangle Park, NC. https://www.epa.gov/sites/production/files/2017-10/documents/final_2008_o3_naaqs_transport_memo_10-27-17b.pdf.

BEIS

Biogenic emissions were computed by U. S. EPA based on the same version of the 2011 meteorology data used for the air quality modeling and were developed using the Biogenic Emission Inventory System version 3.61 (BEIS3.61) within SMOKE. The landuse input into BEIS3.61 is the BELD version 4.1 which is based on an updated version of the USDA-USFS Forest Inventory and Analysis (FIA) vegetation speciation-based data from 2001 to 2014 from the FIA version 5.1.

It is Alpine's opinion that the U.S. EPA application of the BEIS model was appropriate for use in the MPCA SIP.

3. Air Quality Modeling

The MPCA modeling used the Comprehensive Air-quality Model with Extensions (CAMx) air quality model[62]. CAMx is a state-of-science "One-Atmosphere" multi-scale photochemical grid model (PGM) capable of addressing ozone, particulate matter (PM), visibility and acid deposition at regional, urban and local scale typically for periods of a year. CAMx is a publicly available open-source computer modeling system for the integrated assessment of gaseous and particulate air pollution. Built on today's understanding that air quality issues are complex, interrelated, and reach beyond the urban scale, CAMx is designed to (a) simulate air quality over many geographic scales, (b) treat a wide variety of inert and chemically active pollutants including ozone, inorganic and organic $PM_{2.5}$ and PM_{10} and mercury and toxics, (c) provide source-receptor, sensitivity, and process analyses and (d) be computationally efficient and easy to use.

The U.S. EPA has approved the use of CAMx for numerous ozone and PM State Implementation Plans throughout the U.S. and has used this model to evaluate regional mitigation strategies including those for most recent national transport rules, such as the Cross-State Air Pollution Rule (CSAPR), CSAPR Update, and the modeling used in justification of denial of the MPCA SIP. The MPCA used Version 6.4, which was released in December 2016. Unlike some of EPA's previous ozone modeling guidance that specified a particular ozone model (e.g., EPA 1991 Guidance[63]) or that specified the Urban Airshed Model (UAM)[64], the EPA now recommends that

---

[63] Draft Guidance on the Use of Models and Other Analyses in Attainment Demonstrations for the 8-hr Ozone NAAQS". U.S. Environmental Protection Agency, Office of Air Quality Planning and Standards, Research Triangle Park, N.C. May.

[64] User's Guide for the Urban Airshed Model. Volume I: User's Manual for UAM (CB-IV) prepared for the U.S. Environmental Protection Agency (EPA-450/4-90-007a). Systems Applications International, San Rafael, CA.

models be selected for ozone SIP studies on a "case-by-case" basis. The latest EPA ozone guidance[65] (pp. 24) explicitly mentions the CAMx PGMs as one of the most commonly used PGMs that would satisfy EPA's selection criteria but notes that this is not an exhaustive list and does not imply that it is "preferred" over other PGMs that could also be considered and used with appropriate justification.

The CAMx model is updated regularly to both update the science in the model and to address coding errors (bugs) in the code. CAMx 6.5 was released at the end of April 2018, approximately 6 months prior to submission the MPCA SIP submission. It is customary for regulatory modeling to "freeze" the model version during the modeling process to keep the modeling on schedule.

It is Alpine's opinion that the CAMx 6.4 air quality model along with the EPA EN platform with 2023 EGU's updated to include ERTAC was appropriate for use in the MPCA SIP.

4. Model Performance

MPCA relied on the model performance evaluation (MPE) conducted by the U.S. EPA on the modeling platform that we used for this study[66] to establish validity in the modeling platform. In addition to the MPE for the base year CAMx simulation, the U.S. EPA reported full MPE results for the 2011 WRF modeling[67] used in the CAMx simulations.

It is Alpine's opinion that the EPA WRF and CAMx performance evaluations showed adequate performance and that the modeling was appropriate for use in the MPCA SIP.

5. Source Apportionment

MPCA used the CAMx Anthropogenic Precursor Culpability Assessment (APCA) tool to calculate emissions tracers for identifying upwind sources of ozone at downwind monitoring sites. MPCA

[65] Modeling Guidance for Demonstrating Air Quality Goals for Ozone, PM2.5, an Regional Haze. [67] US EPA. 2014. Meteorological Model Performance for Annual 2011 WRFv3.4 Simulation. Research Triangle Park, NC. https://www3.epa.gov/ttn/scram/reports/MET_TSD_2011_final_11-26-14.pdf.

used the APCA technique because it more appropriately associates ozone formation to anthropogenic sources than the CAMx Ozone Source Apportionment Technique (OSAT). If any anthropogenic emissions are involved in a reaction that leads to ozone formation, even if the reaction occurs with biogenic VOC or NOx, APCA tags the ozone as anthropogenic in origin.

The APCA source apportionment tool has a robust theoretical basis and a long application history and it is our opinion that the APCA tool is appropriate for identifying upwind sources of ozone at downwind monitoring sites.

6. Interstate Transport Provisions – Section 110(a)(2)(D)

This section of the CAA requires SIPs to have provisions prohibiting sources from emitting air pollutants in amounts that would contribute significantly to nonattainment or interfere with maintenance in any other state. These interstate transport requirements are often referred to as "good neighbor SIPs". The analyses conducted both by LADCO and EPA to support the 2015 ozone good neighbor SIPs show Minnesota does not contribute significantly to air quality problems in any downwind nonattainment or maintenance area. Therefore, no additional controls or emissions limits were required to fulfill Minnesota's good neighbor obligations.

On March 27, 2018, the EPA published a memo, entitled "Information on the Interstate Transport State Implementation Plan Submissions for the 2015 Ozone National Ambient Air Quality Standards under Clean Air Act Section 110(a)(2)(D)(i)(I)". EPA's Memo included new transport modeling data for the year 2023 (the Moderate Attainment deadline for the 2015 ozone NAAQS). These data are provided to assist states in completing the "good neighbor" SIPs for the 2015 ozone NAAQS, and to thereby address interstate transport obligations.

EPA identifies a four-step framework in the Memo, intended to guide states on how to go about developing good neighbor SIPs:

1. Identify downwind air quality problems;
2. Identify upwind states that contribute enough to those downwind air quality problems to warrant further review and analysis;
3. Identify the emissions reductions necessary (if any), considering cost and air quality factors, to prevent an identified upwind state from contributing significantly to those downwind air quality problems; and
4. Adopt permanent and enforceable measures needed to achieve those emissions reductions.

In Step 1, EPA identifies monitoring sites that are projected to have problems attaining and/or maintaining the NAAQS in the 2023 analytic year. Where EPA's analysis shows that a site does

not fall under the definition of a nonattainment or maintenance receptor, that site is excluded from further analysis under EPA's 4-step interstate transport framework. For sites that are identified as a nonattainment or maintenance receptor in 2023, we proceed to the next step of our 4-step interstate transport framework by identifying the upwind state's contribution to those receptors.

In Step 2, EPA quantifies the contribution of each upwind state to each receptor in the 2023 analytic year. The contribution metric used in Step 2 is defined as the average impact from each state to each receptor on the days with the highest ozone concentrations at the receptor based on the 2023 modeling. If a state's contribution value does not equal or exceed the threshold of 1 percent of the NAAQS (i.e., 0.70 ppb for the 2015 ozone NAAQS), the upwind state is not ''linked'' to a downwind air quality problem, and EPA, therefore, concludes that the state does not significantly contribute to nonattainment or interfere with maintenance of the NAAQS in the downwind states.

Comparably, in MPCA's SIP submission, they include LADCO's modeling which additionally follows the same transport framework and is corroborated by EPA's modeling with the data released with the March 2018 memo.

Step 1 - 2023 Air Quality Projections

MPCA's reported air quality projections[68] submitted with their SIP were based on the ozone modeling conducted by LADCO. The result of this LADCO 2023 modeling, using methods utilized by EPA and shown in Table 9 below, forecasted that no downwind monitors in the Midwest or Northeast would be nonattainment for the 2015 O3 NAAQS.

Table 10. EPA 2023 ozone design values at nonattainment and maintenance monitors in the Midwest and Northeast.

[69] https://www.epa.gov/sites/default/files/2018-05/updated_2023_modeling_dvs_collective_contributions.xlsx

An additional six monitors in Connecticut (90010017 and 90099002), Maryland (240251001), Michigan (260050003 and 261630019), and New York (360810124) would be considered maintenance monitors in the projection.

In neither the LADCO nor EPA modeling cited in MPCA's SIP revision submission were the two Cook County, Illinois monitors (170314201 and 170310076) from EPA's SIP denial NPR, or the single monitor from EPA's final SIP disapproval action, identified as either nonattainment or maintenance monitors in the 2023 projections.

Step 2 - Significant Contribution to Downwind States

EPA has previously determined that a state contribution to downwind air quality problems below one percent of the applicable NAAQS is insignificant. This screening method was used in previous good neighbor SIP approvals, and other regulatory actions including (most notably) the Cross-State Air Pollution Rule (CSAPR), and the CSAPR update for the 2008 ozone NAAQS and 2012 NAAQS for particulate matter less than 2.5 micrometers in diameter (PM2.5). The one percent screening method was developed through several previous federal notice and comment rulemakings. One percent of the 2015 ozone NAAQS (70 ppb) is 0.70 ppb. Therefore, any state that contributes less than 0.70 ppb to a projected nonattainment or maintenance area in another state is not culpable for those air quality problems.

EPA and LADCO applied the Anthropogenic Precursor Culpability Analysis (APCA) technique in CAMx to identify upwind states culpable for downwind ozone air quality problems. The method accounts for anthropogenic nitrogen oxides (NO_x) and volatile organic carbon (VOC) emissions from all sources in each upwind state affecting projected 2023 ozone concentrations at each downwind air quality monitoring site designated a nonattainment or maintenance receptor. EPA and LADCO conducted the culpability analysis for the period May 1 through September 30, using the 2023 future emission estimates and 2011 meteorology.

Both LADCO and EPA analyses[70] conclude Minnesota is not culpable for ozone nonattainment, or interference with maintenance, in any downwind states. As shown in Table 11, prepared using data from MPCA's SIP[71], LADCO's analysis shows a maximum contribution of 0.45 ppb to the identified maintenance monitors, less than the 0.70 ppb identified as 1% of the NAAQS (70 ppb). EPA's analysis[72] (Table 12) indicates Minnesota contributes most to Milwaukee, Wisconsin monitor site 550790085. At a concentration of 0.40 ppb, this contribution is roughly equal to 0.57% of the 2015 ozone NAAQS.

Table 12. EPA 2023 O3 design values at nonattainment and maintenance monitors in the Midwest and Northeast and Minnesota's calculated contribution.

For the reasons set forth in this section, it is our opinion that the modeling conducted and cited by MPCA in the development of its 2015 ozone NAAQS transport SIP revision of October 2018 was technically adequate and appropriate for the purpose it was intended and followed all available EPA guidance on preparing technical modeling for SIP and SIP-related analyses.

Additionally, in our opinion, the MPCA SIP adequately demonstrates that Minnesota is not a significant contributor to any downwind monitor identified as in nonattainment or maintenance for the 2015 ozone NAAQS and is corroborated by EPA modeling which included state-of-science configuration and platform at the time the original SIP was submitted.

D. Summary of Conclusions

For the reasons set forth in this document, it is our opinion that the modeling conducted and cited by MPCA in the development of its 2015 ozone NAAQS transport SIP revision of October 1, 2018 was technically adequate and appropriate for the purpose it was intended and should have been approved by EPA at the time of submission. It is further our opinion that decisions made by EPA to compare MPCA's original submitted modeling to recently updated modeling, developed by EPA over four years and four months later than the original Oct 2018 submission, are inconsistent with EPA precedent.

It is our opinion that in the absence of inclusion of Minnesota's and other stakeholder's valid emission modeling platform revision submissions, as requested by EPA, and multiple reruns of the air quality in both the base year (2016) and projection year (2023) simulations, EPA cannot appropriately identify monitors as nonattainment or maintenance, and in turn, cannot calculate upwind state significant contribution metrics from these same data. Non-EGU emission controls and their associated NOx emission reductions as documented and submitted by MPCA, could be enough to change nonattainment designations and linked significance using an updated platform and needs to be considered before making any final decision on denial of MPCA's SIP.

It is our opinion that EPA's use of modeling with poor performance at critical monitors amounts to an unreliable result when used to establish nonattainment or maintenance monitors under Step 1 or linkages under Step 2 of the 4-step framework. Should more refined modeling be undertaken to review the ozone formation potential at monitors located in these land-water interfaces, results may show that these monitors demonstrate modeled attainment and/or remove significant contribution linkages from upwind states.

It is our opinion that the most recent modeling cited by EPA and used to justify the linkage of Minnesota to one downwind maintenance monitors in Cook County, Illinois has technical issues as it relates to that linked monitor which is located in a complex land-water interface and may require finer grid resolution modeling to adequately capture ozone formation and significant contribution, and that EPA must address the impact of VOC emissions in influencing ozone formation at monitors in Illinois.

It is our opinion that EPA has failed to follow the process by relying on the best available modeling at the time that an analysis is conducted, and results are developed and submitted. Instead, EPA continues to move the target and objectives for states that, in Minnesota's case, for over four years had been waiting for a review of their "best available data and analysis".

It is our opinion that EPA should not have used any updated modeling to support a SIP review while not providing the opportunity for that data to be reviewed, analyzed, and commented on in advance of any final decision on the subject SIP disapproval and that any modeling beyond what was conducted in the original SIP submittal was ancillary to the approval process. However, should EPA decide not to review MPCA's SIP revision on its merit, Alpine recommends that EPA withdraw the SIP disapproval in favor of correcting the technical errors that have been identified in its analysis and to propose an appropriate opportunity for Minnesota to address any deficiencies EPA may find in Good Neighbor Plans implementing the 2015 ozone NAAQS.

It is our opinion that EPA's 2018 flexibility memo has become so instrumental to states in developing their good neighbor SIPs, that EPA's decision to disallow the flexibilities that they themselves outlined in guidance, is unreasonable and should be reconsidered.

Additionally, in our opinion, the MPCA SIP adequately demonstrates that Minnesota is not a significant contributor to any downwind monitor identified as in nonattainment or maintenance for the 2015 ozone NAAQS and is corroborated by EPA modeling which included state-of-science configuration and platform at the time the original SIP was submitted. It is our opinion that the original MPCA SIP was and is approvable.

E. Minnesota 2015 Ozone SIP Timeline

October 1, 2015 – EPA finalized the revised 2015 ozone NAAQS. Pursuant to CAA section 110(a)(1), "each state shall . . . submit to the Administrator, within 3 years. . .after promulgation of a [primary NAAQS] (or any revision thereof) a plan which provides for implementation, maintenance, and enforcement of such primary standard. . ." CAA section 110(a)(2)(D)(i)(I) requires such SIPs to "contain adequate provisions prohibiting . . .any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will contribute significantly to nonattainment in, or interfere with maintenance by, and other State with respect to such NAAQS.

March 27, 2018 - EPA published a memo, entitled "Information on the Interstate Transport State Implementation Plan Submissions for the 2015 Ozone National Ambient Air Quality Standards under Clean Air Act Section 110(a)(2)(D)(i)(I)". EPA's Memo included new transport modeling data for the year 2023 (the Moderate Attainment deadline for the 2015 ozone NAAQS). These data are provided to assist states in completing the "good neighbor" SIPs for the 2015 ozone NAAQS, and to thereby address interstate transport obligations.

October 1, 2018 - Minnesota Pollution Control Agency (MPCA) submitted a SIP revision to address CAA Section 110(a)(2)(D)(i)(I) on October 1, 2018 .[73] The submission met the statutory deadline for submittal the interest transport SIPs for the 2015 ozone NAAQS. The submission utilized both EPA modeling released with the March 2018 memorandum and LADCO modeling results previously mentioned. Minnesota followed the 4-step interstate transport framework and used an analytic year of 2023 to describe Minnesota's lack of contributions to out of state receptors and assess emission reduction considerations.

April 1, 2019 – This is 6 months after EPA received the Minnesota SIP submission and is the date that the CAA deems the Minnesota submittal to have been complete since EPA did not take action otherwise.

September 13, 2019 - The D.C. Circuit issued a decision in *Wisconsin v. EPA*, remanding the CSAPR Update to the extent that it failed to require upwind states to eliminate their significant

[73] **Completeness Finding** - Pursuant to the CAA Section 110(k)(1)(B) "Within 60 days of the Administrator's receipt of a plan or plan revision, but no later than 6 months after the date, if any, by which a State is required to submit the plan or revision, the Administrator shall determine whether the minimum criteria established pursuant to subparagraph (A) have been met. Any plan or plan revision that a State submits to the Administrator, and that has not been determined by the Administrator (by the date 6 months after receipt of the submission) to have failed to meet the minimum criteria established pursuant to subparagraph (a), shall on that date be deemed by operation of law to meet such minimum criteria."

contribution by the next applicable attainment date by which downwind states must come into compliance with the NAAQS, as established under CAA section 181(a). 938 F.3d at 313.

April 1, 2020 – This is 12 months after the completeness date and is the deadline for EPA to have acted on the MN SIP submission. Upon this deadline a full, partial or conditional approval was required by CAA Section 110(k)(2), (3), or (4).[74]

May 19, 2020 - the D.C. Circuit issued a decision in *Maryland v. EPA* that cited the Wisconsin decision in holding that EPA must assess the impact of interstate transport on air quality at the next downwind attainment date, including Marginal area attainment dates, in evaluating the basis for EPA's denial of a petition under CAA section 126(b). Maryland v. EPA, 958 F.3d 1185, 1203-04 (D.C. Cir. 2020). The court noted that "section 126(b) incorporates the Good Neighbor Provision," and, therefore, "EPA must find a violation [of section 126] if an upwind source will significantly contribute to downwind nonattainment at the next downwind attainment deadline. Therefore, the agency must evaluate downwind air quality at that deadline, not at some later date." Id. at 1204 (emphasis added). EPA interprets the court's holding in Maryland as requiring the states and the Agency, under the good neighbor provision, to assess downwind air quality as expeditiously as practicable and no later than the next applicable attainment date, which is now the Moderate area attainment date under CAA section 181 for ozone nonattainment. The Moderate area attainment date for the 2015 ozone NAAQS is August 3, 2024. At the time of the statutory deadline to submit interstate transport SIPs (October 1, 2018), many states relied upon EPA modeling of the year 2023, and no state provided an alternative analysis using a 2021 analytic year (or the prior 2020 ozone season). However, EPA must act on SIP submittals using the information available at the time it takes such action. In this circumstance, EPA does not believe it would be appropriate to evaluate states' obligations under CAA section 110(a)(2)(D)(i)(I) as of an attainment date that is wholly in the past, because the Agency interprets the interstate transport provision as forward looking. See 86 FR at 23074; see also Wisconsin, 938 F.3d at 322. Consequently, in this proposal EPA will use the analytical year of 2023 to evaluate each state's CAA section 110(a)(2)(D)(i)(I) SIP submission with respect to the 2015 ozone NAAQS.

May 12, 2021 – Downwinders at Risk, et al filed Case No. 21 Civ. 21 Civ 3551 asserting that EPA failed to undertake certain non-discretionary duties under the CAA.

---

[74] **Deadline for Action**. – Pursuant to the CAA Section 110(k)(1)(B) "Within 12 months of a determination by the Administrator (or a determination deemed by operation of law) under paragraph (1) that a State has submitted a plan or plan revision (or, in the Administrator's discretion, part thereof) that meets the minimum criteria established pursuant to paragraph (1), if applicable (or, if those criteria are not applicable, within 12 months of submission of the plan or revision), the Administrator shall act on the submission in accordance with paragraph (3)."

February 22, 2022 - EPA assessed the Minnesota submittal and on February 22, 2022 (3 years, 4+ months after submittal) the agency proposed denial of the Minnesota SIP as follows: "Based on EPA's evaluation of Minnesota's SIP submission and after consideration of updated EPA modeling using the 2016-based emissions modeling platform, EPA is proposing to find that the portion of Minnesota's October 1, 2018 SIP submission addressing CAA section 110(a)(2)(D)(i)(I) does not meet the state's interstate transport obligations for 2015 ozone NAAQS, because it fails to contain the necessary provisions to eliminate emissions that will contribute significantly to nonattainment or interfere with maintenance of the NAAQS in any other state. Air Plan Disapproval; Illinois, Indiana, Michigan, Minnesota, Ohio, Wisconsin; Air Plan Disapproval; Region 5 Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 87 Fed. Reg. 9838 (Feb. 22, 2022).

February 28, 2022 – EPA and Downwinders et al established in a Consent Decree entered into on 1/12/2022 that if EPA proposed a full or partial denial of the Minnesota SIP EPA shall have until December 15, 2022 to sign a final action. Note this is a settlement and does not erase the fact that EPA failed to complete its non-discretionary duty to have reviewed and acted upon the MN SIP by April 1, 2020.

April 30, 2022 – EPA and Downwinders, et established in a Consent Decree entered into on 1/12/2022 that required EPA to sign for publication final rulemaking on April 30, 2022 to approve, disapprove, and conditionally approve the Minnesota SIP submissions for the 2015 ozone NAAQS.

May 22, 2022 – EPA proposed to approve most elements of the Minnesota October 1, 2018 submission intended to address all applicable infrastructure requirements for the 2015 NAAQS. (87 FR 31462).

July 29, 2022 – EPA approved most elements of the Minnesota October 1, 2018 SIP submission from Minnesota regarding infrastructure requirements for the 2015 ozone NAAQS. EPA did not act on the interstate transport requirements and visibility impairments requirements. (87 FR 45663).

December 8, 2022 – EPA and Downwinders et al filed a Joint Motion of Stipulated Extension of Consent Decree deadlines that provided the following schedule.

December 15, 2022 – Former agreed upon deadline by Downwinders for EPA to act on Minnesota SIP, but this deadline was moved by agreement to January 31, 2022.

January 31, 2023 - deadline to sign final action on Minnesota SIP pursuant to agreed upon extension of Downwinders Consent Decree.

February 13, 2023 – EPA publishes final disapproval of State Implementation Plan (SIP) submissions for 19 states, including Minnesota. Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 FR 9336.

March 15, 2023 – EPA issues final federal Good Neighbor Plan for the 2015 ozone NAAQS (publication in the Federal Register is still pending).

In re: Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality Standards, 88 Fed. Reg. 36,654 (June 5, 2023)	)))))	EPA Docket No. EPA–HQ–OAR–2021–0668 FRL–8670–02–OAR

Petition for Reconsideration and for Stay of the Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality Standards

ALLETE, Inc. d/b/a Minnesota Power; Northern States Power Company – Minnesota; Great River Energy; Southern Minnesota Municipal Power Agency; Cleveland-Cliffs, Inc.; and United States Steel Corporation (collectively "Petitioners") respectfully request that the United States Environmental Protection Agency ("EPA") reconsider and stay the portion of its final rule Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality Standards, 88 Fed. Reg. 36,654 (June 5, 2023) (the "FIP") that imposes a federal implementation plan on Minnesota for interstate transport of ozone under "prong 2" of Clean Air Act ("CAA") § 110(a)(2)(D)(i)(I), 42 U.S.C. § 7410(a)(2)(D)(i)(I) (the "Good Neighbor Requirements").

Circumstances arising after the close of the public comment period and before the time for judicial review demonstrate that the FIP must be withdrawn. As a result, EPA is required to grant reconsideration and reevaluate both its authority to promulgate the FIP and the propriety of applying the FIP to Minnesota.

First, EPA no longer has authority to promulgate the FIP for Minnesota based on a stay of EPA's disapproval of "prong 2" of Minnesota's State Implementation Plan ("SIP").[1] Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 Fed. Reg. 9336 (February 13, 2023) (the "SIP Disapproval"). Without the SIP Disapproval, EPA's FIP for Minnesota is *ultra vires*. Even in the absence of a judicial stay, however, EPA should reconsider and withdraw the FIP as to Minnesota because Minnesota submitted a timely and approvable SIP. EPA therefore had a nondiscretionary duty to approve it.

Second, the FIP must be reconsidered because the facts on which the FIP was based have been dramatically altered by the stay of EPA's disapproval of SIPs for Minnesota and several other states. For electric generating units ("EGUs") in particular, the viability of a robust trading program that will ensure reasonable costs of compliance and adequate protection of grid reliability can no longer be supported.

Third, EPA's provision of the modeling on which it relied for the FIP after the close of the public comment period has revealed substantial technical errors that, once corrected, support the

[1] EPA has divided the Good Neighbor Requirements set out in Clean Air Act ("CAA") § 110(a)(2)(D), 42 U.S.C. § 7410(a)(2)(D), into two "prongs." The obligation to prohibit sources from emitting air pollutants in an amount which will "contribute significantly to nonattainment" is sometimes referred to as "prong 1," and the obligation to prohibit sources from emitting air pollutants in an amount which will "interfere with maintenance" as "prong 2."

conclusion that Minnesota should not be subject to the FIP. Several of these issues were detailed in Petitioners' prior Petition for Reconsideration and Stay of the SIP Disapproval ("SIP Petition"), which Petitioners incorporate here by reference and attach as Attachment A. But additional flaws have been identified in light of additional modeling EPA provided only with the FIP.

Finally, the new modeling results EPA released with its FIP establish that the FIP over-controls emissions from Minnesota and is therefore without statutory authority.

Because after-arising circumstances show that the FIP should not, and indeed could not, have been promulgated for Minnesota, Petitioners request that EPA grant reconsideration and withdraw the FIP as to Minnesota.

Further, to avoid irreparable injury, Petitioners request that EPA stay the FIP pending reconsideration and pending judicial review.

I. Background

On October 1, 2015, EPA promulgated a revised primary and secondary 8-hour ozone NAAQS of 70 ppb. This created a requirement under the Clean Air Act for states to submit revised SIPs to EPA by October 1, 2018. *See* 42 U.S.C. § 7410(a)(1). SIPs were required to meet the applicable requirements of Clean Air Act, 42 U.S.C. § 7410(a)(2), including the obligations, sometimes referred to as "Good Neighbor" obligations, to:

> (D) Contain adequate provisions—
>
> > (i) prohibiting, consistent with the provisions of this subchapter, any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will—
> >
> > > (I) contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any such national primary or secondary ambient air quality standard….[2]

The obligation to prohibit sources from emitting air pollutants in an amount which will "contribute significantly to nonattainment" is sometimes referred to as "prong 1," and the obligation to prohibit sources from emitting air pollutants in an amount which will "interfere with maintenance" as "prong 2," of the Good Neighbor obligation. EPA concluded that Minnesota complies with prong 1 as it does not contribute significantly to nonattainment in any other State. Minnesota is implicated in the FIP only due to EPA's conclusion that it interferes with maintenance under prong 2 at a single monitor location in Cook County, Illinois.

While EPA has never promulgated regulations imposing more specific interstate transport requirements than what is contained in the statutory text, EPA has developed a 4-step framework that it used to develop the FIP:

[2] 42 U.S.C. § 7410(a)(2)(D).

(1) Identify monitoring sites that are projected to have problems attaining and/or maintaining the NAAQS (i.e., nonattainment and/or maintenance receptors);

(2) identify states that impact those air quality problems in other (i.e., downwind) states sufficiently such that the states are considered ''linked'' and therefore warrant further review and analysis;

(3) identify the emissions reductions necessary (if any), applying a multifactor analysis, to eliminate each linked upwind state's significant contribution to nonattainment or interference with maintenance of the NAAQS at the locations identified in Step 1; and

(4) adopt permanent and enforceable measures needed to achieve those emissions reductions.[3]

While this framework is not binding on States, Minnesota applied it to develop its SIP.[4] In doing so, Minnesota used 2018 modeling that EPA had developed and submitted to States for their use in developing SIPs to identify monitoring sites projected to have problems attaining or maintaining the 2015 ozone NAAQS in 2023.[5] Minnesota also supplemented this modeling with modeling developed by the Lake Michigan Air Directors Consortium ("LADCO").[6] Both models showed that Minnesota contributed less than 1 percent of the NAAQS to all downwind receptors, with a highest receptor contribution from either model of 0.45 ppb.[7] Thus, following EPA's 4-factor framework, and using EPA's own modeling, Minnesota demonstrated that it was not contributing significantly to, or interfering with maintenance of, the 2015 ozone NAAQS in any downwind state.

Notably, Minnesota took a conservative approach in reaching this conclusion. In three guidance memoranda, EPA identified multiple areas where States could exercise flexibility in developing their SIPs, including in the Transport Memo itself, a separate memorandum published later that year supporting a threshold higher than 1% for determining significant contributions and interference with maintenance at step 2,[8] and a memorandum published after the SIP submission

deadline identifying flexibilities States could use in identifying maintenance-only monitors.[9] Minnesota's SIP submission demonstrated that Minnesota had met its Good Neighbor requirements even without exercising any of these flexibilities.[10] In other words, while Minnesota was not required to, it followed EPA's own framework and did not rely on additional flexibilities to demonstrate that it had satisfied its Good Neighbor obligations.[11]

This alone would have been sufficient to satisfy Minnesota's Good Neighbor obligation. Minnesota also, however, included in its SIP submission a "step 3" analysis demonstrating that Minnesota emissions of ozone precursors had been reduced from 2002 through 2015 and would be further reduced by emission limitations and reductions required by other programs.[12] Under this step 3 analysis, Minnesota demonstrated that, even if the state were having more than an insignificant impact on downwind receptors (as EPA now asserts), Minnesota's existing glidepath of emissions reductions still supported a finding that no further emission control measures would be needed to address this impact. EPA did not meet its obligation to approve or deny Minnesota's complete and approvable SIP within 12 months of submittal.

Approximately three years after EPA's deadline to approve the Minnesota SIP, EPA proposed to disapprove Minnesota's SIP on February 22, 2022, along with SIPs from 18 other states.[13] EPA did not identify a technical error in Minnesota's submission or any inconsistency with the Good Neighbor requirements, or even EPA's own framework. In fact, EPA recognized that "the modeling the MPCA used relied on the most recently available EPA modeling at the time the state submitted its SIP submittal."[14] Nonetheless, EPA proposed to reject Minnesota's SIP because EPA chose to rely "on the Agency's most recently available modeling, which uses a more recent base year and more up-to-date emissions inventories, to identify upwind contributions and 'linkages' to downwind air quality problems in 2023 using a threshold of 1 percent of the NAAQS."[15] EPA called this new modeling its "2016v2" modeling.[16] Based on this alternative modeling, EPA proposed to reject Minnesota's conclusion that it was not linked to a downwind

[9] Consideration for Identifying Maintenance Receptors for Use in Clean Air Act Section 110(a)(2)(D)(i)(I) Interstate Transport State Implementation Plan Submissions for the 2015 Ozone National Ambient Air Quality Standards, https://www.epa.gov/sites/default/files/2018-10/documents/maintenance_receptors_flexibility_memo.pdf at 3 (Oct. 19, 2018) ("Maintenance Memo").
[10] 2018 SIP at 6.
[11] Minnesota, of course, could have taken a different approach, and might have used some of these flexibilities, had EPA indicated during the statutory review period that it was considering disapproving prong 2 of Minnesota's SIP.

receptor, and to find instead that Minnesota was linked to two maintenance monitors in Cook County, Illinois, one with a maximum contribution of 0.97 ppb and the other 0.79 ppb.[17]

Less than two months after proposing to disapprove Minnesota's SIP, EPA proposed its own FIP for Minnesota along with 25 other states.[18] EPA used the same 2016v2 modeling as the basis for its FIP.[19] Relying on this modeling, EPA proposed to find that Minnesota "is significantly contributing to downwind nonattainment or interfering with maintenance of the 2015 ozone NAAQS in other states, based on projected nitrogen oxides (NO_x) emissions in the 2023 ozone season."[20]

On February 13, 2023, EPA published the SIP Disapproval. In its final rule, EPA approved Minnesota's SIP as to "prong 1" but disapproved Minnesota's SIP as to "prong 2."[21] Rather than use the emissions data and modeling available to Minnesota in 2018, or even emissions data and modeling available at the time of the proposed SIP disapproval, EPA made a number of additional updates to its emissions inventories and model design to construct a new 2016v3 emissions platform, which it used to generate new air quality modeling without seeking public comment to allow affected party input to help the agency assess the accuracy of the new information utilized in the modeling.[22] Minnesota was now no longer linked to two downwind receptors. It was now linked to only a single maintenance-only receptor, at a maximum contribution of 0.85 ppb for 2023.[23] While EPA also conducted updated modeling for 2026, it did not release this information in the docket for the SIP Disapproval, stating it was "not applicable" and "not used in this final action."[24]

Only a month later, the Administrator signed the FIP and EPA made the full modeling results for the 2016v3 platform available to the public.[25] Based on EPA's modeling for 2026, Minnesota is not linked to any downwind nonattainment or maintenance-only receptor in its base case modeling, with the largest contribution to downwind nonattainment or maintenance-only receptors being 0.32 ppb.[26] In fact, the sole maintenance-only receptor Minnesota was linked to in 2023 in EPA's 2016v3 modeling is modeled in attainment in EPA's 2026 modeling.[27] Notably, this modeling assumes no installation of additional pollution controls in Minnesota. Indeed, the

[22] *See id.* at 9,339.
[23] *Id.* at 9,357.
[24] *Id.* at 9,344, n.49.
[25] https://www.epa.gov/csapr/good-neighbor-plan-2015-ozone-naaqs.
[26] FIP at 36,710, Table IV.F–2; *see also id.* at 36,660 (finding Minnesota will not "continue to contribute above the 1 percent of the NAAQS threshold to at least one receptor whose nonattainment and maintenance concerns persist through the 2026 ozone season").
[27] *Id.* at 36,743, Table V.D.1–2.

only emissions reductions included from Good Neighbor obligations in EPA's modeling are an annual reduction of 139 tons NOx from emissions control optimization at EGUs.[28]

Despite the minimal connection of a single maintenance-only receptor that is modeled to be in attainment by 2026 without any FIP-based reductions from Minnesota, the FIP concludes that Minnesota "is significantly contributing to nonattainment or interfering with maintenance of the 2015 ozone NAAQS in downwind states, based on projected ozone precursor emissions in the 2023 ozone season." FIP at 36,656. As a result, the FIP requires Minnesota to participate for the first time in EPA's revised version of the Cross-State Air Pollution Rule ("CSAPR") NO_x Ozone Season Group 3 Trading Program beginning in the 2023 ozone seas. *Id.* at 36,657-58.

At Step 3 of its framework, EPA did not separately analyze States significantly contributing to nonattainment versus interfering with maintenance. As a result, EPA determined that all States, regardless of their downwind impact, would be required to implement "emissions reductions commensurate with the full operation of all existing post-combustion controls (both SCRs and SNCRs) and state-of-the-art combustion control upgrades." *Id.* at 36,660. The result is that Minnesota is subject to the same "Group 3 trading program budget-setting methodology," the same "preset ozone season NOx emissions budgets for each ozone season from 2023 through 2029," and the same "enhancements," such as dynamic budget setting, recalibration of banked allowances, and backstop daily emissions rate as States significantly contributing to nonattainment. *Id.* at 36,662-63.[29]

Several Petitioners petitioned for judicial review of the SIP Disapproval in *ALLETE v. EPA*, Case No. 23-1776 (8th Cir.), and moved to stay the SIP Disapproval pending judicial review. The motion was granted and the Eighth Circuit stayed the SIP Disapproval on July 5, 2023.[30] Petitioners understand from conversations with the United States Department of Justice ("DOJ") that EPA considers the FIP inapplicable to Minnesota while the stay is in place. And indeed EPA has acknowledged that a stay of the FIP is necessary to comply with court-ordered stays of other SIP disapprovals. *See* Federal ''Good Neighbor Plan'' for the 2015 Ozone National Ambient Air Quality Standards; Response to Judicial Stays of SIP Disapproval Action for Certain States, 88 Fed. Reg. 49,295 (July 31, 2023) ("Interim Final Rule"). To date, however, EPA has taken no regulatory action to withdraw or stay the FIP for Minnesota. Action has been taken only in the form of an interim final rule for the States of Arkansas, Kentucky, Louisiana, Mississippi, Missouri, and Texas. *Id.*

---

[28] Compare *id.* at 36,737, Table V.C.1-1; 36,738, Table V.C.1-2; and 36,785-86, Table VI.B.4.c-1.

[29] Minnesota's EGU budgets for 2026 and beyond do not reflect additional emission reductions achievable after 2026 and Minnesota is not subject to non-EGU requirements applicable to other states starting in 2026. *Id.* at 36,660 and 36,691, n.117. These differences from most States are due to Minnesota not being linked to any nonattainment or maintenance-only receptor as of 2026, not to EPA giving independent significance state as a maintenance-only State or its limited impact on only a single maintenance-only receptor before 2026.

[30] Order ("Stay Order"), *ALLETE, Inc. v. EPA*, Case No. 23-1776, ECF 5292580 (8th Cir. July 5, 2023).

II. Grounds for Reconsideration of the SIP Disapproval

Under the Clean Air Act, reconsideration is *required* "[i]f the person raising an objection can demonstrate to the Administrator that it was impracticable to raise such objection within such time or if the grounds for such objection arose after the period for public comment (but within the time specified for judicial review) and if such objection is of central relevance to the outcome of the rule."[31] Courts have found that an objection was "impractical to raise" "when the final rule was not a logical outgrowth of the proposed rule." *Alon Refining Krotz Springs, Inc. v. EPA*, 936 F.3d 628, 648 (D.C. Cir. 2019) (*per curiam*). In other words, when interested parties would not have "anticipated that the change was possible, and thus reasonably should have filed their comments on the subject during the notice-and-comment period." *CSX Transp., Inc. v. Surface Transp. Bd.*, 584 F.3d 1076, 1080 (D.C. Cir. 2009) (internal quotations omitted). An objection is of central relevance to the outcome of the rule if it "provides substantial support for the argument that the regulation should be revised." *Chesapeake Climate Action Network v. EPA*, 952 F.3d 310, 322 (D.C. Cir. 2020). Under the Administrative Procedure Act ("APA"), EPA has "broad discretion to reconsider" its regulatory actions "at any time." *Clean Air Council v. Pruitt*, 862 F.3d 1, 8-9 (D.C. Cir. 2017).[32]

Significant developments since the close of the of the public comment period on the FIP require reconsideration. First, due to the after-arising Stay Order, EPA does not have authority to promulgate the FIP for Minnesota. It therefore must be withdrawn. Notably, even without the Stay Order, EPA's modeling results, released without opportunity for public comment, confirm that Minnesota's SIP submission was approvable at the time it was submitted, underscoring that EPA should not have issued the FIP for Minnesota and should now withdraw it. Second, the after-arising Stay Order, combined with similar stays of SIP disapprovals issued by courts for nine other States, undermines the factual foundation on which EPA constructed the FIP and renders the FIP no longer tenable. Third, the FIP is not a logical outgrowth of the Proposed FIP. EPA's modeling platform changed significantly, as did the modeling results for Minnesota. The result is a FIP for which Petitioners did not have notice or an opportunity to comment. Because EPA did not have the benefit of notice and comment on its 2016v3 modeling, EPA was also unable to address significant errors in its modeling platform prior to finalization of the FIP that undermine its conclusion that Minnesota should be subject to the FIP. Finally, in light of EPA's new modeling, the FIP clearly overcontrols NO_x emissions from Minnesota, which is prohibited by the Supreme Court's interpretation of the Clean Air Act. *EPA v. EME Homer City Generation, L.P.* 572 U.S. 489, 523 (2014) ("EPA has a statutory duty to avoid over-control").

---

[31] 42 U.S.C. § 7607(d)(7)(B).

[32] *See also Trujillo v. Gen. Elec. Co.*, 621 F.2d 1084, 1086 (10th Cir. 1980) ("Administrative agencies have an inherent authority to reconsider their own decisions, since the power to decide in the first instance carries with it the power to reconsider."); *United Gas Improvement Co. v. Callery Properties, Inc.*, 382 U.S. 223, 229 (1965) ("An agency, like a court, can undo what is wrongfully done by virtue of its order.")

A. EPA Does Not Have Authority to Promulgate the FIP for Minnesota.

1. The Stay Order Renders the FIP Ultra Vires as to Minnesota.

Minnesota submitted an approvable SIP in 2018. In February 2023, EPA approved "prong 1" of Minnesota's SIP based on EPA's finding that Minnesota does not contribute significantly to nonattainment in any downwind state. EPA disapproved Minnesota's SIP as to "prong 2," finding that Minnesota was linked to interference with maintenance of a single downwind maintenance-only receptor. SIP Disapproval at 9,357. That action, however, was challenged by several Petitioners and the Eighth Circuit has stayed the disapproval of Minnesota's SIP pending judicial review. Stay Order.

The Stay Order was issued July 5, 2023, "after the period for public comment (but within the time specified for judicial review)." 42 U.S.C. § 7607(d)(7)(B). It is also of central relevance to the FIP. The Clean Air Act requires EPA to first disapprove a SIP, or find that the States has failed to submit a SIP, before EPA can promulgate a FIP. 42 U.S.C. § 7410(c)(1). EPA has acknowledged already that the stay of similar SIP disapprovals for other States deprives it of authority to issue the FIP for those States. Interim Final Rule ("EPA must act to ensure that the Good Neighbor Plan's requirements…in each of the states for which a stay order has been issued will not take effect while the stay of the SIP Disapproval action as to that state remains in place."). The Stay Order therefore renders the FIP for Minnesota *ultra vires.* 42 U.S.C. § 7607(d)(9); *Bowen v. Georgetown Univ. Hospital*, 488 U.S. 204, 208 (1988) ("It is axiomatic that an administrative agency's power to promulgate legislative regulations is limited to the authority delegated by Congress."); *U.S. ex rel. O'Keefe v. McDonnell Douglas Corp.*, 132 F.3d 1252, 1257 (8th Cir. 1998) ("An agency's promulgation of rules without valid statutory authority implicates core notions of the separation of powers, and we are required by Congress to set these regulations aside.").

On reconsideration, EPA should withdraw the FIP for Minnesota. While EPA has, as of the date of this submission, taken no official action on the FIP for Minnesota, EPA has begun to act with respect to several states for which similar judicial stays have been issued. Interim Final Rule at 49,295 (taking action with respect to "Arkansas, Kentucky, Louisiana, Mississippi, Missouri, and Texas only"). Petitioners note that, in acting with respect to Minnesota, action identical to EPA's Interim Final Rule would be insufficient. The Interim Final Rule issues a "stay [that] is limited to requirements for which the EPA does not currently have authority to implement…pending judicial review." *Id*. This is insufficient for two reasons. First, the Clean Air Act requires EPA to disapprove the State's SIP before it can "*promulgate* a Federal implementation plan." 42 U.S.C. § 7410(c)(1) (emphasis added). EPA cannot promulgate, and then stay, the FIP. It must withdraw it. *See Union Pacific Railroad Co. v. Dept. of Homeland Security*, 738 F.3d 885, 900 (8th Cir. 2013) (agency action that is "'unlawful'…must be 'set aside'") (quoting 5 U.S.C. § 706(2).

Second, merely staying the FIP will not fulfill the requirements of the Stay Order. A stay pending judicial review is issued to preserve the *status quo* and prevent the incurrence of imminent and irreparable harm pending judicial review. *See Nken v. Holder*, 556 U.S. 418, 426 (2009). The Interim Final Rule stays the effective date of the FIP but it makes no provision for modifying the deadlines in the FIP that will apply if the FIP is not vacated after the stay is lifted. As a result, even as modified by the Interim Final Rule, there is no provision in the FIP to extend deadlines applicable to Minnesota when the stay is lifted to allow the time needed to come into compliance. The result is that Petitioners must either trust EPA enforcement discretion and equitable relief, or be prepared to participate in the Group 3 trading program on a moment's notice.

To mitigate this risk, Petitioners will need to take many of the same actions that they would have been required to take had the FIP not been stayed (which again EPA has not done for Minnesota). This would not effectuate the stay order issued by the Eight Circuit. EPA must reconsider its FIP and withdraw it or, at a minimum, both stay the effective date of the FIP as to Minnesota and extend all applicable deadlines for the duration of the stay.

2. EPA Has a Nondiscretionary Duty to Approve Minnesota's SIP

Even absent a judicial stay of the SIP Disapproval, EPA should reconsider and withdraw the FIP as to Minnesota because Minnesota submitted a timely and approvable SIP. As discussed in Petitioners' SIP Petition, which is attached hereto and incorporated by reference, Minnesota timely submitted a SIP that meets the requirements of the Clean Air Act. As a result, EPA has a nondiscretionary duty to approve Minnesota's SIP.

While EPA conducted modeling after the SIP submission deadline that EPA believes brings into question the adequacy of Minnesota's SIP, this does not give EPA the authority to disapprove Minnesota's SIP. The Clean Air Act sets forth specific procedures for addressing information that arises after an approvable SIP is submitted, and none involve disapproval of a pending SIP submission. Further, EPA has not attempted to use any of these procedures to address the after-arising 2016v3 modeling.

Further, while it was improper for EPA to use the SIP approval process to introduce its 2016v3 modeling, as discussed in the attached SIP Petition, the 2016v3 modeling has data errors for Minnesota emission units and significant bias at the key modeling receptor at which EPA found a purported link to Minnesota. Correcting this bias alone would demonstrate even under the 2016v3 modeling that Minnesota has no link to a downwind nonattainment or maintenance-only receptor and that the conclusions in Minnesota's 2018 SIP are still correct.

B. The Factual Predicate for the FIP is No Longer Supportable.

In addition to the Stay Order, SIP disapprovals for nine other States have been stayed as of the filing of this petition after the close of the public comment period but before the time for judicial review: Arkansas, Kentucky, Louisiana, Mississippi, Missouri, Nevada, Oklahoma, Texas, and Utah.[33] Additional motions to stay are pending.[34] As discussed above, since these SIP disapprovals were EPA's legal prerequisite for promulgation of the FIP, EPA has already recognized that it now lacks authority to apply the FIP to these States pending judicial review. Moreover, because a stay is predicated on a finding a likelihood of success on the merits, there is a substantial likelihood that the FIP will never apply to most or all of these States. *See Nken*, 556 U.S. at 434.

These States represent a large portion of the emission allowances that EPA assumed would be available for trading in the Group 3 trading program, both to maintain a reasonable cost of compliance and to ensure adequate grid reliability. *See* FIP at 36,766, n.295 (the "trading program…depend[s] on the existence of a marketplace for purchasing and selling allowances"); *id.* at 36,789 (noting the importance of "allowance market liquidity" especially during the 2024-2029 period); *id.* at 36,774 (citing "the use of a trading program as the mechanism for achieving…emissions reductions" as a factor in finding no "material risk of adverse impact to electric system reliability" and as the reason why additional accommodation for "reliability-related need" was unnecessary). The emissions reductions from these States were also a significant factor in the policy cases used by EPA for its IPM modeling with Steps 1 and 2 and its AQAT modeling for Steps 3 and 4. Accordingly, the legal and factual basis for the FIP has so fundamentally changed that the FIP can no longer stand on the current administrative record.

EPA must therefore reconsider the FIP and determine whether, in light of the inapplicability of the FIP for the above states pending judicial review (which may extend into the 2024 ozone trading season) and likely permanently, requires modification or withdrawal of the FIP for those remaining States, as well as the above States.

C. The FIP is Based on Evidence that was Not Subject to Notice and Comment.

1. The FIP Relies on Modeling That was Not Publicly Available until EPA Signed the FIP.

The proposed FIP was based on modelling that EPA refers to as its "2016v2" modeling. *See* FIP at 36,673. The public comment period closed in June 2022 without any change in EPA's modeling, but EPA did not rely on the 2016v2 results for the FIP. Instead, EPA "revised its 2016v2 modeling platform and input since the platform was made available for comment" to create the 2016v3 modeling. *Id.* at 36,674. It then "reassessed" its modeling results "to inform the final

[33] *See* Unpublished Order, *Texas v. EPA*, Case No. 23-60069, ECF 269-1 (May 1, 2023) (staying Texas and Louisiana SIP disapprovals); *Arkansas v. EPA*, Case No. 23-1320, ECF 5280996 (May 25, 2023) (staying Arkansas SIP disapproval); Order, *Missouri v. EPA*, Case No. 23-1719, ECF 5281126 (May 26, 2023) (staying Missouri SIP disapproval); Unpublished Order, *Texas v. EPA*, Case No. 23-60069, ECF 359-2 (June 8, 2023) (staying Mississippi SIP disapproval); *Nevada Cement Co. v. EPA*, Case No. 23-682, ECF 27.1 (July 3, 2023) (staying Nevada SIP disapproval); Order, *Kentucky v. EPA*, Case No. 23-3216, ECF 39-2 (July 25, 2023) (staying Kentucky SIP disapproval); Order, *Utah v. EPA*, Case No. 23-9509, ECF 010110895101 (July 27, 2023) (staying Oklahoma and Utah SIP disapprovals).

[34] *See Ohio v. EPA*, Case No. 23-1183 (D.C. Cir); *West Virginia v. EPA*, Case No. 23-1418 (4th Cir.); *Alabama v. EPA*, Case No. 23-11196 (11th Cir.).

action." *Id.* These were not minor amendments. EPA "evaluated a raft of technical information and critiques of its 2016v2 modeling" and "incorporated updates into the version of the modeling used to support this final rule (2016v3)." *Id.* Further, while EPA released some of its 2016v3 results with the SIP Disapproval in February 2023, it withheld the results for model year 2026, asserting that these results were "not applicable and were not used in this final action." SIP Disapproval at 9,344, n.30. As a result, EPA did not release the full modeling results on which the FIP is based until it signed the FIP in March 2023.

This was "highly improper." *Small Ref. Lead Phase-Down Task Force v. EPA*, 705 F.2d 506, 540 (D.C. Cir. 1983); *see also Kennecott Corp. v. EPA*, 684 F.2d 1007, 1019 (D.C. Cir. 1982) (finding EPA had not provided adequate opportunity for public comment on economic modeling placed in the docket only one week before promulgation of its final regulations). EPA's rulemaking process requires adequate public notice and an opportunity to comment. *Small Ref.*, 705 F.2d at 547. This includes providing the public with the evidence on which EPA intends to rely. *Id.* at 540. If "documents of central importance upon which EPA intended to rely ha[ve] been entered on the docket too late for any meaningful public comment prior to promulgation, then both the structure and spirit of section 307 [are] violated." *Sierra Club v. Costle*, 657 F.2d 298, 400 (D.C. Cir. 1981).

EPA's late addition of modeling central to its FIP alone justifies reconsideration.

2. The FIP Omitted Public Comment on Critical Modeling Inputs, Leaving Reconsideration the Only Option for Correcting Material Errors.

Because EPA did not submit its 2016v3 modeling to notice and comment, EPA could not benefit from public review of EPA's emissions data and model results. The new emissions inventory and modeling platform are of central relevance to EPA's rule. EPA identifies the 2016v3 platform as "the version of the modeling used to support this final rule." FIP at 36,674. Further, while the FIP asserts that its "modeling on the whole has provided consistent outcomes regarding which states are linked to downwind air quality problems," EPA acknowledges this is not the case for Minnesota, which "went from being unlinked to being linked in 2023 between the 2011-based modeling provided in the March 2018 memorandum and the 2016v3-based modeling." *Id.* Moreover, while this linkage is present in both the 2016v2 and 2016v3 modeling, it is far more attenuated in the 2016v3 modeling, which identifies only a single maintenance-only receptor, to which Minnesota is "linked" by a maximum modeled contribution of 0.85 ppb. *See id.* at 36,710, Table IV.F–1.

While there have been errors in each of EPA's modeling at each stage of the regulatory process, the errors in the 2016v3 emissions inventory and modeling arose only with the publication of the final SIP Disapproval and FIP. As a result, errors in EPA's 2016v3 modeling could not have been submitted to EPA during the public comment period for the FIP, which closed in June 2022.

In their SIP Petition, Petitioners identified material errors in the limited time Petitioners had to review the 2016v3 data prior to the time for judicial review. SIP Petition at 8-10. This included significant errors in EPA's estimate of NOx emissions for 2023, such as EPA's addition of 2,822 tons of NOx for Northshore Mining Co. – Silver Bay power for boilers that have been idled since October 2019 and are expected to have zero emissions in 2023. *Id.* at 8. It also included identification of significant bias in the majority of modeled days used to establish a link to Minnesota. *Id.* at 9-10. These errors were obviously not corrected before EPA relied on the same modeling to support the FIP, since the Administrator had already signed the FIP a month earlier. They are, however, centrally relevant to EPA's determination that Minnesota should be subject to the FIP. As addressed in the SIP Petition, correcting bias outside EPA guidelines alone would likely result in Minnesota no longer being linked to any downwind maintenance-only receptors. *Id.* at 10.

Since the submission of the SIP Petition, Petitioners have identified additional discrepancies in EPA's air quality modeling. As discussed in the attached Report of Alpine Geophysics, Attachment C ("Report"), EPA failed to appropriately estimate 2023 base case emissions for multiple upwind EGU sources using IPM, thereby compromising the modeled downwind ozone concentrations, associated downwind monitor nonattainment designations, and the resulting significant contribution calculations on which EPA relied, not just for Minnesota, but for every state with a modeled contribution to the Alsip/Village Garage receptor (the sole receptor creating a "link" to Minnesota in the FIP). Report at 51. If EPA had properly characterized emissions from these States using historical operation trends (as it did in the Step 3 process), the Alsip/Village Garage receptor may have been modeled in attainment, not as a maintenance receptor, removing Minnesota from the FIP at Step 2. *Id.*

Given the above considerations and Minnesota's unique circumstances, EPA should grant reconsideration to reassess Minnesota's impact on downwind maintenance of attainment to determine whether further emission reductions in a FIP are needed for Minnesota to satisfy its prong 2 Good Neighbor obligations.

D. The FIP Overcontrols Emissions from Minnesota.

The Supreme Court has made clear that EPA cannot implement a FIP that "over-controls" emissions by requiring "reductions unnecessary to downwind attainment *anywhere.*" *EME Homer City*, 572 U.S. at 522 (emphasis in original). In particular, courts will find over-control "when those downwind locations [to which a State has been linked] would achieve attainment even if less stringent emissions limits were imposed on the upwind States linked to those locations." *EME Homer City Generation, L.P. v. EPA*, 795 F.3d 118, 127 (D.C. Cir. 2015). Similarly, the Supreme Court has noted that "EPA is limited, by the second part of the [Good Neighbor] provision, to reduce only by 'amounts' that 'interfere with *maintenance*,' i.e., by just enough to permit an already-attaining State to maintain satisfactory air quality." *EME Homer City*, 572 U.S. at 515, n.18 (quoting 42 U.S.C. § 7410) (emphasis in original); *see also EME Homer City*, 795 F.3d at 127, n.4 ("The Supreme Court held that the same was true for upwind States that 'interfere with maintenance' at downwind locations.").

EPA acknowledged that Minnesota is not significantly interfering with attainment of the NAAQS in any downwind State when it approved prong 1 of Minnesota's SIP. SIP Disapproval at 9,357. Thus, the "reductions" the FIP imposes on Minnesota are "unnecessary to downwind attainment anywhere." *EME Homer*, 572 U.S. at 522. EPA concluded in the FIP that Minnesota should nonetheless be subject to the FIP because of a single modeled maintenance-only receptor to which EPA determined that Minnesota has a maximum impact of 0.85 ppb in 2023. *See* FIP at 36,710, Table IV.F–1.

EPA's own 2016v3 modeling for 2026, however, shows that this same receptor will be in full attainment by 2026 with no reductions from Minnesota other than already "on the books" rules and regulations.[35] In other words, EPA's 2026 modeling establishes that the sole receptor linking Minnesota in the FIP "will achieve attainment even if less stringent emissions limits were imposed on the upwind States linked to those locations." *EME Homer City*, 795 F.3d at 127. Indeed, it will achieve attainment even if *no* emission limits are imposed in the FIP. This is the definition of over-control.

EPA also cannot reasonably assert that Minnesota should be subject to the FIP to prevent interference with maintenance before 2026. First, even in the two ozone seasons (at most) that the FIP would apply to Minnesota, EPA's modeling projects an impact on the Alsip/Village Garage monitor of approximately 0.0010 ppb.[36] This *de minimis* contribution cannot be said to be necessary to eliminate to "permit an already-attaining State to maintain satisfactory air quality." *EME Homer City*, 795 F.3d at 127, n.4. Second, even if this were the case, it would not justify continued application of the FIP to Minnesota in 2026 and beyond, as the FIP does.

EPA's modeling results were not made publicly available until 2023. As a result, they clearly arose "after the period for public comment (but within the time specified for judicial review)." 42 U.S.C. § 7607(b)(1). They are also of central relevance to the FIP as applied to Minnesota. As the Supreme Court has made clear, a FIP that results in over-control is "outside the Agency's statutory authority." *EME Homer City*, 572 U.S. at 522. EPA must therefore grant reconsideration and modify the FIP as to Minnesota to eliminate over-control. Moreover, because EPA's own modeling shows that no emission reductions from Minnesota are needed for attainment of the NAAQS in every downwind State, EPA should find on reconsideration that no emission reductions are needed from Minnesota to satisfy the State's Good Neighbor obligations.

III. Grounds for Stay of the FIP.

EPA has authority to stay the FIP both pending reconsideration and pending judicial review. First, a stay pending reconsideration can be granted for three months. 42 U.S.C. § 7607(d)(7). Second, EPA has authority under the APA to stay the FIP pending judicial review.

A. A Stay Pending Reconsideration is Appropriate.

The Clean Air Act provides that, if EPA grants reconsideration of a rule, "[t]he effectiveness of the rule may be stayed during such reconsideration…by the Administrator or the

---

[35] *See* Air Quality Modeling Final Rule Technical Support Document, https://www.epa.gov/system/files/documents/2023-03/AQ%20Modeling%20Final%20Rule%20TSD.pdf at 17, Table 3-5 (showing Monitor 170310001 no longer listed as a monitor-only receptor in the 2026 base case).

[36] *S*ee Ozone AQAT Final, EPA-HQ-OAR-2021-0668-1116 (comparing 2023 Base Case tab [2023_step3_base; value 0.850667659939893 ppb] with SCR/SNCR Optimization tab [2023_step3_SNCRopt; value 0.849648804871336 ppb]).

court for a period not to exceed three months." 42 U.S.C. § 7607(d)(7)(B). A stay pending reconsideration is justified here.

As discussed above, the FIP was not legally promulgated for Minnesota and cannot now be enforced.

Further, EPA issued a final rule based primarily on emissions data and modeling that it did not make publicly available before issuance of the final rule. Even upon publication, EPA's release of data was partial and inadequate to reconstruct the modeling that EPA used for its final determinations. Obtaining the data and checking its accuracy has taken several weeks. It would take many more weeks to rerun EPA's modeling to confirm the results in the FIP and identify additional areas of concern to those raised in this Petition.

EPA will also likely need time to evaluate the errors Petitioners have identified already and discussed above. This modeling will likely require several weeks and, given the likelihood that it will result in withdrawal or modification of the FIP as to Minnesota, should be evaluated before the FIP is made applicable to Minnesota.

A stay will also not unduly impact downwind states. The FIP cannot be enforced in Minnesota during the pendency of the current SIP Disapproval litigation, which will likely not be resolved for the duration of a reconsideration stay, which is limited to three months. Moreover, Minnesota is not modeled to contribute to nonattainment in any downwind state, and under EPA's most recent modeling, Minnesota is linked only to a single maintenance-only receptor for which EPA's own modeling shows the receptor will be in full attainment by 2026 without any reductions from Minnesota. As a result, a stay pending reconsideration will have no impact on downwind attainment or maintenance of the NAAQS.

B. EPA Should Stay the Effective Date of the FIP Pending Judicial Review.

Under the APA, EPA may stay the effective date of the FIP pending judicial review when "justice so requires." 5 U.S.C. §705. Multiple petitions have already been filed for judicial review, including petitions by Texas, Utah, Ohio, Indiana, West Virginia, and Oklahoma. More are likely, including a petition for judicial review of EPA's FIP for Minnesota, which is being filed contemporaneously with this Petition. These cases are already spread across three circuits, and additional litigation may expand the number of courts further.

The effective date of the FIP is August 4, 2023, but the FIP already cannot be applied in several states, including Minnesota, because of stays of the SIP Disapprovals required to authorize promulgation of the FIP. A stay pending judicial review will simply reflect the legal reality that is already mandated by stays of EPA's SIP Disapproval. Further, the significant legal flaws in EPA's FIP discussed above, coupled with the technical and legal concerns it raises, make it likely that judicial review will result in a remand if not vacatur of the FIP. As a result, to avoid the unnecessary expenditure of EPA resources on a FIP, state resources on FIP implementation, and the resources of the public and regulatory industries in addressing a FIP that is likely to not be required, justice requires that the FIP be stayed pending judicial review.

Further, while EPA is not bound to apply the same four-factor analysis used by courts for granting a judicial stay pending review, these factors indicate support for EPA in granting a stay of the FIP. Under this standard, the considerations for a stay are:

1. whether the stay applicant has made a strong showing that he is likely to succeed on the merits;
2. whether the applicant will be irreparably injured absent a stay;
3. whether issuance of the stay will substantially injure the other parties interested in the proceeding; and
4. where the public interest lies.

Nken v. Holder, 556 U.S. 418, 434, 129 S.Ct. 1749, 173 L.Ed.2d 550 (2009) (citation omitted). These "four considerations are factors to be balanced and not prerequisites to be met." *State of Ohio ex rel. Celebrezze v. Nuclear Regul. Comm'n*, 812 F.2d 288, 290 (6th Cir. 1987).

1. Petitioners Have Made a Strong Showing They Are Likely to Succeed on the Merits

There is no fixed probability of success the agency must find in applying these considerations. "Ordinarily the party seeking a stay must show a strong or substantial likelihood of success. However, at a minimum the movant must show 'serious questions going to the merits and irreparable harm which decidedly outweighs any potential harm to the defendant if a [stay] is issued.'" *Id. (quoting In re DeLorean Motor Company*, 755 F.2d 1223, 1229 (6th Cir.1985)).

As discussed above, the FIP has substantive and procedural flaws, each of which individually, and more so when combined, demonstrate "a high probability of success on the merits." *Ohio ex rel. Celebrezze v. Nuclear Regul. Comm'n.*, 812 F.2d 288, 290 (6th Cir.1987). Substantively, EPA's FIP for Minnesota is *ultra vires*, was based on an incorrect set of emissions data, biased modeling results, and overestimation of emissions that, when adjusted, support the conclusion that Minnesota's is not contributing to nonattainment or interfering with maintenance in any downwind state and does not need to impose additional emission reductions to satisfy its Good Neighbor obligations. Procedurally, EPA did not provide notice and comment on modeling that is central to EPA's decision to impose a FIP on Minnesota and to the level of stringency the FIP can reflect without constituting over-control. In doing so, EPA deprived Petitioners of their statutorily-guaranteed right to participate in the rulemaking process.

More generally, the FIP does not reflect the cooperative federalism required by the Clean Air Act. As EPA has previously acknowledged, "[t]he CAA establishes a framework for state-Federal partnership to implement the NAAQS based on 'cooperative federalism.'" SIP Disapproval at 9,367. Under this model, "the Federal Government establishes broad standards or goals, states are given the opportunity to determine how they wish to achieve those goals, and if states choose not to or fail to adequately implement programs to achieve those goals, a Federal agency is empowered to directly regulate to achieve the necessary ends." *Id.* Thus, "states have the obligation and opportunity in the first instance to develop an implementation plan to achieve the NAAQS under CAA section 110" and "EPA will approve SIP submissions under CAA section 110 that fully satisfy the requirements of the CAA." *Id.*

Under this framework, EPA is given two years following disapproval of a SIP to promulgate a FIP. 42 U.S.C. § 7410(c)(1). While the Supreme Court has stated that "EPA is not obliged to wait two years or postpone its action even a single day" after disapproving a SIP,[37] this should not be read as a license to run roughshod over State attempts to fulfill their primary role under the Clean Air Act. EPA must still interpret its obligations under the Clean Air Act "with a view to their place in the overall statutory scheme," and cannot act in a manner that is "'incompatible with 'the substance of Congress' regulatory scheme.'" *UARG v. EPA*, 573 U.S. 302, __ (2014) (*quoting FDA v. Brown & Williamson Tobacco Corp.*, 529 U.S. 120, 133 and 156 (2000)). Here, EPA departed from Congress' regulatory scheme when it proposed a FIP just one month after *proposing* to disapprove Minnesota's SIP and the Administrator signed the FIP just one month after finalization of the SIP Disapproval, despite Minnesota having timely submitted a complete SIP that meets all requirements of the Clean Air Act.

Because EPA's FIP is *ultra vires*, over-controls emissions from Minnesota, was procedurally improper, and undermines the core cooperative federalism embodied in CAA § 110, Petitioners are likely to prevail on the merits of a judicial challenge. This further supports EPA issuing a stay of the effective date of the SIP Disapproval pending judicial review.

2. Petitioners Will Suffer Irreparable Harm from a Denial of Stay.

Relevant factors for evaluating the harm which will occur both if the stay is issued and if it is not, the court must look to three factors: the substantiality of the injury alleged, the likelihood of its occurrence, and the adequacy of the proof provided. *Ohio ex re. Celebrezze*, 812 F.2d at 290 (*citing Cuomo v. United States Nuclear Regulatory Commission*, 772 F.2d 972, 974 (D.C. Cir.1985)).

The FIP poses substantial and imminent injuries to Petitioners. As discussed above, the FIP has been promulgated without statutory authority. This places the entire State of Minnesota under an *ultra vires* regulation. While EPA has made clear that it does not consider the FIP enforceable while the Stay Order is in place, this does not prevent third parties from seeking to enforce it on their own behalf. *See* 42 U.S.C. § 7604. Petitioners should not have to bear court costs seeking to defend and dismiss claims that are brough only because EPA has not withdrawn a regulation it acknowledges it was without statutory authority to promulgate, and such imminent threats of litigation are an irreparable injury. *See Newman v. Nazcr Trac Prop. Owners Ass'n, Inc.*, 601 F. Supp. 3d 357, 367 (E.D. Wis. 2022) ("the irreparable harm is traceable to Defendants because Plaintiffs are under the certain threat of enforcement").

In addition, the Stay Order says the FIP only by preventing its application in Minnesota. The Stay Order does not address the deadlines that would apply to Petitioners if it is lifted. Absent a stay of the FIP itself, or further modification of the deadlines in the FIP, Petitioners could become subject to compliance obligations without sufficient time to meet them unless they act now in preparation for compliance. Needing to comply with an invalid regulation is also an irreparable

[37] *EME Homer City*, 572 U.S. at 509.

harm. *See Thunder Basin Coal Co. v. Reich*, 510 U.S. 200, 220-21 (1994) ("complying with a regulation later held invalid almost always produces the irreparable harm of nonrecoverable compliance costs.") (Scalia, J., concurring in part and in the judgment).

3. Staying the FIP will not Significantly Injure Other Parties.

As discussed above, emission reductions from Minnesota are not needed for any downwind state to attain the NAAQS, and they are likely not needed to prevent interference with maintenance of the NAAQS in any downwind state. Moreover, the FIP cannot be applied in Minnesota pending judicial review of the SIP Disapproval, which will likely mean that the FIP will not apply for the remainder of the 2023 ozone trading season, and possibly the start of the 2024 ozone trading season as well. As a result, a stay is unlikely to harm any third party.

4. The Public Interest Lies in Granting a Stay.

As courts have held, there is a public interest enjoining inequitable conduct and in minimizing unnecessary costs to be met from public coffers. *See, e.g. B & D Land & Livestock Co. v. Conner*, 534 F. Supp. 2d 891, 910 (N.D. Iowa 2008). Here, the public interest supports a stay. As discussed above, EPA's FIP is without statutory authority and was promulgated through the inequitable exclusion of public participation on the data central to EPA's FIP. The result will be costly public expenditures, both by Minnesota and Petitioners, to prepare for a FIP that will likely never be implemented and in any event is unnecessary.

While it was an error for EPA to promulgate the FIP, EPA can ameliorate the harm of this error by staying the effect of the FIP until the merits of the issues above can be fully evaluated and addressed.

IV. Conclusion

The State of Minnesota has expended substantial effort and resources to regulate the emission of NOx within its borders. Those efforts have successfully reduced State impacts on downwind receptors to a point that Minnesota is not a significant contributor to nonattainment or interference with maintenance of the 2015 ozone standard in any State. Based on the best available data and modeling science available at the time, Minnesota assessed its impact on downwind states, as it was required to do under the Clean Air Act, and appropriately concluded that it was not interfering with maintenance of attainment in any State. EPA should have approved that SIP. Instead, it rushed to promulgate a FIP that it now does not have authority to promulgate and that is based on factual assumptions EPA can no longer maintain. Further, in promulgating the FIP, EPA committed technical and procedural errors that undermine public participation and resulted in a FIP that exceeds EPA's authority by overcontrolling emissions from Minnesota.

Because circumstances arising after the close of the public comment period and before the time for judicial review demonstrate that the FIP must be withdrawn, EPA is obligated to grant reconsideration and should withdraw the FIP as to Minnesota in its entirety. Further, to avoid the significant and irreparable harm to Petitioners arising from EPA's erroneous promulgation of the FIP, EPA should stay the FIP as applied to Minnesota pending reconsideration and pending judicial review.

Please contact our counsel, Douglas.McWilliams@Squirepb.com, to set up a meeting to discuss reconsideration of the FIP.

Petition for Reconsideration and for Stay of the Air Plan Disapprovals for Interstate Transportation of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards

ALLETE, Inc. d/b/a Minnesota Power; Northern States Power Company – Minnesota d/b/a/ Xcel Energy; Great River Energy; Southern Minnesota Municipal Power Agency; Cleveland-Cliffs, Inc.; and United States Steel Corporation (collectively "Petitioners") respectfully request that the United States Environmental Protection Agency ("EPA") reconsider and stay the portion of its final rule Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 Fed. Reg. 9336 (February 13, 2023) (the "SIP Disapproval") that disapproves Minnesota's state implementation plan ("SIP") for interstate transport for "prong 2" of Clean Air Act ("CAA") § 110(a)(2)(D)(i)(I), 42 U.S.C. § 7410(a)(2)(D)(i)(I).

Minnesota is uniquely situated in the SIP Disapproval. In EPA's February 13 action, Minnesota's SIP was approved for "prong 1"[1] based on EPA's finding that Minnesota does not contribute significantly to nonattainment in any downwind state. Minnesota's SIP was disapproved for "prong 2," with EPA finding that Minnesota was linked to interference with maintenance of a single downwind maintenance-only receptor. EPA has subsequently found in its promulgation of an ozone transport federal implementation plan ("FIP") that Minnesota was not linked to any downwind non-attainment or maintenance-only receptor when modeled for 2026.

Based on the best evidence available in 2018 when Minnesota submitted its SIP to EPA for approval (and on April 1, 2020 when EPA had a statutory obligation to approve or deny the Minnesota SIP), Minnesota was ***not*** linked to interference with attainment or maintenance in any downwind state. But, EPA did not timely act on the Minnesota SIP, and then it moved the goal posts. Based on new modeling and emission data EPA developed years later, (the "2016v2" modeling platform) EPA proposed to find that Minnesota was linked to two downwind maintenance-only receptors due to a modeled impact of less than 1 ppb at each receptor. In the

[1] As discussed on page 4 *infra*, EPA has divided the Good Neighbor obligation set out in Clean Air Act ("CAA") § 110(a)(2)(D), 42 U.S.C. § 7410(a)(2)(D), into two "prongs." The obligation to prohibit sources from emitting air pollutants in an amount which will "contribute significantly to nonattainment" is sometimes referred to as "prong 1," and the obligation to prohibit sources from emitting air pollutants in an amount which will "interfere with maintenance" as "prong 2."

final SIP Disapproval, EPA again revised its emissions data and modeling (the "2016v3" modeling platform) and now finds that Minnesota is linked in 2023 to only a single maintenance-only monitor, at a maximum contribution of 0.85 ppb. Further, EPA has since released updated modeling results for 2026 that show that this same monitor will be in attainment without any material reduction of emissions from Minnesota. As a result, after five years of updates, EPA's modeling results support the same conclusion that Minnesota reached in 2018, namely that additional emissions reductions are not needed to prohibit emissions in Minnesota that will contribute significantly to nonattainment, or interfere with maintenance of, the 2015 8-hour ozone NAAQS in any downwind state. We ask that EPA grant this petition for reconsideration to do what it should have done in 2018—Approve the Minnesota SIP.

The approvability of Minnesota's original SIP submittal is corroborated by two additional pieces of information that were not available during the public comment period for the proposed SIP disapproval or prior to EPA's release of its 2016v3 modeling in 2023. First, EPA's 2016v3 emissions inventory materially overstates Minnesota's 2023 NOx emissions; for example, it incorrectly assumes over 2,800 tons of NOx from an electric generating facility that has been idled since 2019 and is projected to have zero emissions in 2023. By merely correcting the projected actual NOx emissions, Minnesota has already achieved more NOx reductions than EPA's FIP would require of Minnesota. This effectively confirms Minnesota's step 3[2] conclusion in its 2018 SIP that no additional permanent or enforceable measures were needed beyond those already implemented by the state.[3]

Second, as EPA has recognized, its CAMx modeling is subject to significant bias in areas of complex meteorology, including the water/land interface occurring at the sole maintenance monitor that EPA has linked to Minnesota emissions. While EPA released with the final SIP Disapproval a review of this localized bias risk for southern Lake Michigan, that review was materially flawed and does not address the significant over-prediction bias occurring on the precise days EPA selected for use in evaluating Minnesota's SIP. As a result, EPA's general conclusion that adjusting for bias will not affect the outcome of its SIP reviews, does not apply to its review of the Minnesota SIP. To the contrary, adjusting for material bias results in the sole maintenance-only monitor to which Minnesota was linked by EPA becoming an attainment monitor in 2023. In other words, eliminating high-bias days alone completely addresses EPA's objection to Minnesota's 2018 SIP and eliminates Minnesota at Step 1 of EPA's four-step analysis.

Reconsideration is appropriate to make the above corrections to the emissions inventory and to account for modeling bias. After incorporating this new material information into the SIP analysis, we believe that EPA will conclude as we have that Minnesota's original 2018 SIP determination that it is not having a downwind impact on attainment or maintenance that requires additional permanent and enforceable measures was correct and warrants approval of

---

[2] *See* page 4 *infra* for the list of four steps in EPA's 4-step framework for evaluating Good Neighbor SIP submissions.

[3] *See* Minnesota's 110(a)(1) and 110(a)(2) "Infrastructure" State Implementation Plan requirements for the National Ambient Air Quality Standards for Ozone, Promulgated in 2015, EPA-R05-OAR-2022-0006-0005, at 12 (October 1, 2018) ("2018 SIP").

the Minnesota SIP. Reconsideration is also appropriate to address a significant procedural flaw in the finalization of the SIP Disapproval. Specifically, the SIP Disapproval relies on information that was not available to EPA, Minnesota, or any other interested parties until 2023, well past the period for Minnesota's SIP submission and EPA's statutory deadline to approve Minnesota's SIP. While EPA has an obligation to use the best available evidence in making its regulatory decisions, that obligation is not unbounded and cannot be used to circumvent the procedures set forth in the Clean Air Act. When Minnesota timely submitted a SIP that is approvable based on the information known at the time, EPA had an obligation to approve the SIP. The Act does not allow EPA unfettered discretion to delay approval until new information becomes available, and then move the goalposts. For States that have done their part to invest resources in developing a timely and approvable SIP, EPA has a statutory obligation to act. EPA may still consider new scientific data and modeling after the statutory deadline, but there is a separate administrative process available to EPA that respects the State's SIP process. Minnesota should have an approved SIP and EPA should be considering whether new information is sufficiently material to require a "SIP call" pursuant to CAA § 110(k)(5), 42 U.S.C. § 7410(k)(5), to give Minnesota the opportunity to revise its SIP given the new available information. Having chosen to use this new information to disapprove prong 2 of Minnesota's SIP instead, EPA deprived Petitioners, the State, and other interested parties of significant procedural protections and opportunities for public input that were required by the Clean Air Act. Granting reconsideration allows EPA the opportunity to cure the procedural flaw that its final action is based on material information that has not been subject to the notice and comment process.

Given that new information was made available after the close of the public comment period, but before the time for judicial review, that such information actually undermines EPA's basis for disapproving prong 2 of Minnesota's 2018 SIP in the SIP Disapproval, and reconsideration would address the harms caused by significant procedural defects in the SIP Disapproval, Petitioners respectfully request that EPA grant reconsideration for the purpose of reviewing this new information and approving prong 2 of Minnesota's 2018 SIP.

Further, since the disapproval of prong 2 of Minnesota's SIP, and the continued implementation of EPA's subsequently-issued FIP, will cause irreparable harm to Petitioners, we request that EPA grant a stay of the disapproval of prong 2 of Minnesota's SIP pending reconsideration and pending judicial review, which will also address the irreparable harm caused by EPA's FIP.

I. Background

On October 1, 2015, EPA promulgated a revised primary and secondary 8-hour ozone NAAQS of 70 ppb. This created a requirement under the CAA for states to submit revised SIPs to EPA by October 1, 2018.[4] SIPs were required to meet the applicable requirements of CAA § 110(a)(2), 42 U.S.C. § 7410(a)(2), including an obligation, sometimes referred to as a "Good Neighbor" obligation, that the SIPs:

[4] 42 U.S.C. § 7410(a)(1).

(D) Contain adequate provisions—

> (i) prohibiting, consistent with the provisions of this subchapter, any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will—
>
> > (I) contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any such national primary or secondary ambient air quality standard, …

42 U.S.C. § 7410(a)(2)(D). The obligation to prohibit sources from emitting air pollutants in an amount which will "contribute significantly to nonattainment" is sometimes referred to as "prong 1," and the obligation to prohibit sources from emitting air pollutants in an amount which will "interfere with maintenance" as "prong 2," of the Good Neighbor obligation.

While EPA has never promulgated regulations imposing more specific interstate transport requirements than what is contained in the statutory text, EPA has developed a 4-step framework that it stated the agency would use to evaluate a state's compliance with its Good Neighbor obligation. Namely:

(1) Identify monitoring sites that are projected to have problems attaining and/or maintaining the NAAQS (i.e., nonattainment and/or maintenance receptors);

(2) identify states that impact those air quality problems in other (i.e., downwind) states sufficiently such that the states are considered ''linked'' and therefore warrant further review and analysis;

(3) identify the emissions reductions necessary (if any), applying a multifactor analysis, to eliminate each linked upwind state's significant contribution to nonattainment or interference with maintenance of the NAAQS at the locations identified in Step 1; and

(4) adopt permanent and enforceable measures needed to achieve those emissions reductions.[5]

Minnesota took a notably conservative approach in its SIP. First, in EPA's Transport Memo, EPA recognized that its four-step framework was not binding, and offered that states "have flexibility to follow this framework or develop alternative frameworks."[6] Despite this flexibility, Minnesota adopted EPA's framework for its SIP.[7] Second, EPA made clear, in the

[6] *Id.*

[7] 2018 SIP at 5.

Transport Memo and in a separate memorandum published later that year, that states did not need to adopt EPA's suggested 1% threshold for determining significant contributions and interference with maintenance at step 2.[8] Here too, Minnesota did not exercise this flexibility, and chose instead to use EPA's preferred approach.[9] Third, EPA guidance offered states flexibility regarding how to determine which downwind monitors should be considered maintenance receptors.[10] Again, Minnesota followed EPA's suggested approach.[11] In other words, while Minnesota was not required to, it followed EPA's own framework and did not rely on additional flexibilities to demonstrate that it had satisfied its Good Neighbor obligations.[12]

Minnesota also used the best information available at the time to determine its Good Neighbor obligations. Specifically, Minnesota used EPA's own modeling and modeling developed by the Lake Michigan Air Directors Consortium ("LADCO") to identify monitoring sites projected to have problems attaining or maintaining the 2015 ozone NAAQS in 2023.[13] It then projected the state's own contributions to those nonattainment and maintenance monitors using both sets of results.[14] Both EPA's and LADCO's modeling showed that Minnesota would contribute less than 1 percent of the NAAQS to all downwind receptors, with a highest receptor contribution from either model of 0.45 ppb.[15] Thus, following EPA's 4-factor framework, and using EPA's own modeling and proposed threshold, Minnesota demonstrated that it was not contributing significantly to, or interfering with maintenance of, the 2015 ozone NAAQS in any downwind state.

This alone would have been sufficient to satisfy Minnesota's Good Neighbor obligation. Minnesota also, however, included in its SIP submission a "step 3" analysis demonstrating that Minnesota emissions of ozone precursors had been reduced from 2002 through 2015 and would be further reduced by emission limitations and reductions required by other programs.[16] Under this step 3 analysis, Minnesota demonstrated that, even if the state were having more than an insignificant impact on downwind receptors (as EPA now asserts), Minnesota's existing glidepath of emissions reductions still supported a finding that no further emission control measures would

[16] *Id.* at 9-12; *see also id.* at 13.

be needed to address this impact. EPA did not meet its obligation to approve or deny Minnesota's complete and approvable SIP within 12 months of submittal.

Approximately three years after EPA's deadline to approve the Minnesota SIP, EPA proposed to disapprove Minnesota's SIP on February 22, 2022, along with SIPs from 18 other states.[17] EPA did not identify a technical error in Minnesota's submission or any inconsistency with the Good Neighbor requirements, or even EPA's own framework. In fact, EPA recognized that "the modeling the MPCA used relied on the most recently available EPA modeling at the time the state submitted its SIP submittal."[18] Nonetheless, EPA proposed to reject Minnesota's SIP because EPA chose to rely "on the Agency's most recently available modeling, which uses a more recent base year and more up-to-date emissions inventories, to identify upwind contributions and 'linkages' to downwind air quality problems in 2023 using a threshold of 1 percent of the NAAQS." *Id.* Based on this data, EPA proposed to reject Minnesota's conclusion that it was not linked to a downwind receptor, and to find instead that Minnesota was linked to two maintenance monitors in Cook County, Illinois, one with a maximum contribution of 0.97 ppb and the other 0.79 ppb.[19]

On February 13, 2023, EPA published the SIP Disapproval. In its final rule, EPA approved Minnesota's SIP as to "prong 1" but disapproved Minnesota's SIP as to "prong 2."[20] Rather than use the emissions data and modeling available to Minnesota in 2018, or even emissions data and modeling available at the time of the proposed SIP disapproval, EPA made a number of additional updates to its emissions inventories and model design to construct a new 2016v3 emissions platform, which it used to generate new air quality modeling without seeking public comment to allow affected party input to help the agency assess the accuracy of the new information utilized in the modeling.[21] Minnesota was now no longer linked to two downwind receptors. It was now linked to only a single maintenance-only receptor, at a maximum contribution of 0.85 ppb for 2023.[22]

While EPA also conducted updated modeling for 2026, it did not release this information in the docket for the SIP Disapproval, stating it was "not applicable" and "not used in this final action."[23] EPA subsequently made these results available, however, on EPA's website for its Federal Implementation Plan ("FIP") for 23 states, including Minnesota.[24] Based on EPA's modeling for 2026, Minnesota is not linked to any downwind nonattainment or maintenance-only receptor. In fact, based on EPA's modeling, the sole maintenance-only receptor Minnesota was linked to in 2023 is in attainment by 2026, and Minnesota's largest contribution to any

downwind nonattainment or maintenance-only receptor is just 0.32 ppb.[25] Notably, this modeling assumed no installation of additional pollution controls in Minnesota. The only emissions reductions included from Good Neighbor obligations were an annual reduction of 139 tons NOx from emissions control optimization at EGUs.[26]

II. Grounds for Reconsideration of the SIP Disapproval

Reconsideration is justified under either CAA § 307(d)(7)(B)[27] or Administrative Procedure Act ("APA") § 553(e) (5 U.S.C. § 553(e)).[28] Under CAA § 307(d), reconsideration is *required* "[i]f the person raising an objection can demonstrate to the Administrator that it was impracticable to raise such objection within such time or if the grounds for such objection arose after the period for public comment (but within the time specified for judicial review) and if such objection is of central relevance to the outcome of the rule."[29] Courts have found that an objection was "impractical to raise" "when the final rule was not a logical outgrowth of the proposed rule." *Alon Refining Krotz Springs, Inc. v. EPA*, 936 F.3d 628, 648 (D.C. Cir. 2019) (*per curiam*). In other words, when interested parties would not have "anticipated that the change was possible, and thus reasonably should have filed their comments on the subject during the notice-and-comment period." *CSX Transp., Inc. v. Surface Transp. Bd.*, 584 F.3d 1076, 1080 (D.C. Cir. 2009) (internal quotations omitted). An objection is of central relevance to the outcome of the rule if it "provides substantial support for the argument that the regulation should be revised." *Chesapeake Climate Action Network v. EPA*, 952 F.3d 310, 322 (D.C. Cir. 2020). Under the APA, EPA has "broad discretion to reconsider" its SIP Disapproval "at any time" Under the APA. *Clean Air Council v. Pruitt*, 862 F.3d 1, 8-9 (D.C. Cir. 2017).[30]

Three grounds support reconsideration under either standard. First, EPA's 2016v3 modeling did not have the benefit of Petitioners' or other public comments. As a result, it contains a significant overestimation of 2023 emissions for Minnesota. Second, EPA's 2016v3 modeling of the sole monitor supporting a potential linkage between Minnesota and Illinois is subject to significant bias which, if corrected for, results in the same receptor modeling attainment in 2023. Third, EPA's rejection of prong 2 of Minnesota's SIP was procedurally

[25] *See* Federal "Good Neighbor Plan" for the 2016 Ozone National Ambient Air Quality Standards, https://www.epa.gov/system/files/documents/2023-03/FRL%208670-02-OAR_Good%20Neighbor_Final_20230314_Signature_ADMIN%20%281%29.pdf, at 198 (pre-publication version).

[27] 42 U.S.C. § 76076(d)(7)(B).
[28] SIP disapprovals are not automatically subject to the exhaustion requirements of Clean Air Act § 307(d). 42 U.S.C. § 7607(d). This subsection lists 22 categories of agency action subject to the exhaustion requirement. SIP approval and disapproval, separate from issuance of a FIP, as occurred in the SIP Disapproval, is not addressed by any of these 22 categories.
[29] 42 U.S.C. § 7607(d)(7)(B).
[30] *See also Trujillo v. Gen. Elec. Co.*, 621 F.2d 1084, 1086 (10th Cir. 1980) ("Administrative agencies have an inherent authority to reconsider their own decisions, since the power to decide in the first instance carries with it the power to reconsider."); *United Gas Improvement Co. v. Callery Properties, Inc.*, 382 U.S. 223, 229 (1965) ("An agency, like a court, can undo what is wrongfully done by virtue of its order.")

improper because it was based entirely on results EPA obtained in 2023, well past the statutory deadline for Minnesota's SIP submission and EPA's decision approving or disapproving it.

A. Errors in EPA's New Emissions Data and Modeling, Which Were Not Subject to Notice and Comment, Support Reconsideration to Ensure EPA's Decision on Minnesota's SIP is Based on Valid and Accurate Information.

EPA "made a number of updates to [its] inventories and model design to construct a 2016v3 emissions platform which was used to update [EPA's] air quality modeling." SIP Disapproval at 9339. The SIP Disapproval uses "this updated modeling to inform [EPA's] final action on [state] SIP submissions," including Minnesota's. *Id.*

The new emissions inventory and modeling platform are of central relevance to EPA's rule. EPA identifies the 2016v3 platform as designed "to inform [the agency's] final action on these SIP submissions." SIP Disapproval at 9339. For Minnesota, the 2016v3 modeling results are the sole record citation EPA provides for its finding that prong 2 of Minnesota's SIP was "ultimately inadequate." *Id.* at 9357.

While there have been errors in each of EPA's inventories at each stage of the regulatory process, these new errors in the emissions inventory arose only with the publication of the final SIP Disapproval. Under both the APA and the CAA, EPA's rulemaking process requires adequate public notice and an opportunity to comment on the evidence on which EPA intends to rely for its final rules.[31] EPA's emissions inventory and modeling design changes were not made publicly available until EPA published the SIP Disapproval and several supporting documents on the same day. As a result, the public, including Petitioners, did not have the opportunity to review EPA's data and correct errors before then.

In the limited time Petitioners have had to review the 2016v3 data, we have identified significant errors in EPA's estimate of NOx emissions for 2023. As an example, EPA added 2,822 tons of NOx for Northshore Mining Co. – Silver Bay power. These boilers have been idled since October 2019 and are expected to have zero emissions in 2023. EPA itself recognizes that zero emissions are expected at this facility in both its OTP Policy Analysis, Appendix A and in its Unit-Level Allocations and Underlying Data for the Final Rule (both available at https://www.epa.gov/csapr/good-neighbor-plan-2015-ozone-naaqs). Yet EPA made no adjustment to its 2016v3 data, resulting in a significant overestimate of 2023 emissions from Minnesota used by EPA to justify disapproval of the Minnesota SIP. If EPA defends including 2,822 tons of NOx emissions for Silver Bay Power in the baseline actual emissions used to model Minnesota's downwind impact in 2023, then Minnesota's state allowance budget should be

[31] *See Small Ref. Lead Phase-Down Task Force v. EPA*, 705 F.2d 506, 540 (D.C. Cir. 1983) (adding evidence on which EPA relies after the close of the comment period would be "highly improper"); *see also Sierra Club v. Costle*, 657 F.2d 298, 400 (D.C. Cir. 1981) ("If … documents of central importance upon which EPA intended to rely had been entered on the docket too late for any meaningful public comment prior to promulgation, then both the structure and spirit of section 307 would have been violated."); *see also Kennecott Corp. v. EPA*, 684 F.2d 1007, 1019 (D.C. Cir. 1982) (finding EPA had not provided adequate opportunity for public comment on economic modeling placed in the docket only one week before promulgation of its final regulations).

increased to reflect those emissions and Silver Bay Power should receive proportional allowance allocations for the 2023 CSAPR ozone season trading program and beyond. To do otherwise would be internally inconsistent, which is an indication of arbitrary rulemaking.

For Minnesota, EPA's most recent modeling identified a single impacted maintenance monitor in 2023, at which Minnesota's maximum impact was 0.85 ppb. EPA's latest modeling projects this same receptor will be in attainment by 2026 with no reductions from Minnesota other than already "on the books" rules and regulations.[32] In other words, EPA's 2026 modeling confirms Minnesota's 2018 SIP conclusion that "the limits and controls that Minnesota already has in place across the state are sufficient to make it reasonably certain that Minnesota will not significantly contribute to nonattainment or interfere with maintenance in any other state" and that "no further controls or emissions limits are required to fulfill [Minnesota's] responsibilities under the interstate transport provisions for the 2015 ozone NAAQS under prongs 1 and 2 of Section 110(a)(2)(D)(i)(I)."[33]

Given the above considerations, EPA should grant reconsideration to reassess Minnesota's 2018 SIP in light of its own modeling showing that no further emission reductions are needed for Minnesota to satisfy its prong 2 good neighbor obligations.

B. The Sole Monitor that Links Minnesota Models in Attainment for 2023 When Bias is Removed.

Minnesota's only link to a downwind state receptor is the Alsip/Village Garage monitor located in Cook County, Illinois (170310001). This monitor is located near the southern shore of Lake Michigan at a land-water interface with complex meteorology**.** This monitor is currently measuring attainment with the 2015 ozone NAAQS using the 2021 4th highest daily maximum value (68 ppb). However, EPA's air quality modeling predicts that this monitor is at risk of violating the ozone NAAQS and, therefore, designates it as a maintenance-only receptor. Upwind states that interfere with this monitor's maintenance of the ozone NAAQS are linked through prong 2**.** However, if a corrected model predicts the monitor's maximum 2023 design value will attain the 2015 ozone NAAQS, this monitor falls out of the analysis at Step 1 and, since no other monitor links to Minnesota, EPA will have no basis for disapproval of prong 2 of Minnesota's SIP.

In the attached analysis, Alpine Geophysics demonstrates that the Cook County monitor models attainment for the 2015 ozone NAAQS in 2023. Alpine Geophysics evaluated this Cook County monitor and concluded that its location at a land-water interface at the southern shore of Lake Michigan presents highly complex meteorological conditions and ozone photochemistry that complicate the air quality model's ability to replicate ozone concentrations reliably. Of note,

---

[32] *See* Air Quality Modeling Final Rule Technical Support Document, https://www.epa.gov/system/files/documents/2023-03/AQ%20Modeling%20Final%20Rule%20TSD.pdf at 17, Table 3-5 (showing Monitor 170310001 no longer listed as a monitor-only receptor in the 2026 base case).
[33] 2018 SIP at 13.

EPA's application of a 12 km grid resolution in such areas is contrary to EPA's own guidance.[34] Alpine Geophysics reviewed EPA's day-specific model performance for the estimation of ozone concentrations on days EPA used to calculate future year design values and found significant bias in the majority of modeled day values used to designate this monitor site as a maintenance-only receptor. When Alpine Geophysics adjusted for this bias by using daily concentration values within acceptable normalized bias boundaries (+/- 15%), the updated list of top ten days used to designate the Cook County monitor resulted in both its average and maximum design values to be calculated in attainment with the 2015 ozone NAAQS.

When one attaining monitor modeled as a maintenance-only receptor is the sole basis for a state's linkage, a refined level of analysis is particularly important when predicting future design values and significant contribution**.** When that monitor is in a highly complex land-water interface area, it is not surprising for refined analysis to show significant bias**.** In its FIP rulemaking, EPA looked at this impact, but evaluated only one of ten Cook County monitors.[35] In doing so, EPA evaluated the only monitor out of the ten where EPA's performance-based recalculation resulted in a higher design value. As a result, EPA's sensitivity analysis materially understates the significance of the bias impact on the Alsip/Village Garage monitor and this issue remains central to EPA's evaluation of Minnesota's 2018 SIP.

Petitioners also had no ability to evaluate the bias in EPA's 2016v3 modeling of the Alsip/Village Garage monitor prior to EPA's release of its model and supporting data. As a result, this information arose after the close of the public comment period and within the time for judicial review.

Since Petitioners have identified significant bias in the sole receptor on which EPA relies to find a link to Minnesota and reject Minnesota's 2018 SIP, reconsideration is appropriate to evaluate the new information and analysis provided. When reasonably adjusting for the bias in EPA's 2016v3 modeling of that receptor, EPA will be in a position to confirm that Minnesota accurately concluded in 2018 that there are no "potential nonattainment or maintenance receptors significantly impacted by ozone transport from Minnesota in 2023" and that "[t]herefore, Minnesota does not have a responsibility to identify or implement any further controls or emissions limits to reduce downwind ozone contribution."[36]

C. Minnesota's SIP Should Have Been Approved Based on the Data Available at the Statutory Deadlines for Submission or Review.

The Clean Air Act sets out a detailed process for EPA's review of SIPs in CAA § 110(k). 42 U.S.C. § 7410(k). For timely submitted plans that have been deemed complete, like Minnesota's,

---

[34] Modeling Guidance for Demonstrating Air Quality Goals for Ozone, $PM_{2.5}$ and Regional Haze, https://www.epa.gov/sites/default/files/2020-10/documents/o3-pm-rh-modeling_guidance-2018.pdf (Nov. 29, 2018).

[35] *See* Federal "Good Neighbor Plan for the 2015 Ozone National Ambient Air Quality Standards Response to Public Comments on Proposed Rule, https://www.epa.gov/system/files/documents/2023-03/Response%20To%20Comments%20Document%20Final%20Rule.pdf at 196.

[36] 2018 SIP at 9.

EPA has twelve months to act on a plan submission. 42 U.S.C. § 7410(k)(2). For a plan that meets the requirements of the Clean Air Act, "the Administrator shall approve such submittal as a whole." *Id.* at (k)(3). If a portion of the plan revision meets all the applicable requirements, EPA "may approve the plan revision in part and disapprove the plan revision in part" but "[t]he plan revision shall not be treated as meeting the requirements of [the Clean Air Act] until the Administrator approves the entire plan revision as complying with the applicable requirements of [the Clean Air Act]." *Id.* In other words, while EPA has discretion to partially approve a SIP submittal that does not meet all requirements of the Clean Air Act, if a submission meets all requirements of the Act, EPA does not have discretion. It must approve the SIP. *See also Utah Physicians for a Healthy Env't v. Kennecott Utah Copper, LLC*, 191 F. Supp. 3d 1287, 1290 (D. Utah 2016) ("If a SIP satisfies the applicable requirements, EPA must approve it.").

In 2018, Minnesota submitted a timely and approvable SIP. As EPA acknowledges in the SIP Disapproval, Minnesota "was not projected to be linked to any receptor in 2023 in the EPA's 2011-based modeling."[37] Petitioners retained Alpine Geophysics to reanalyze Minnesota's SIP submission considering the best evidence available both at the time of Minnesota's SIP submission and at the time of EPA's statutory obligation to approve or disapprove Minnesota's SIP. As detailed in the attached report, Alpine Geophysics' review confirms that Minnesota's SIP submission: (1) had no material errors; (2) relied on the best science (including emissions data and modeling) available at the time; (3) fully complied with the CAA's requirements and EPA's guidance; and (4) would have been approved had EPA not incorporated information unavailable during the statutory review period. As a result, pursuant to 42 U.S.C. § 7410(k)(2) and (k)(3), by April 1, 2020, EPA had a non-discretionary duty to approve Minnesota's SIP. While EPA missed its statutory deadline, this did not relieve EPA of its duty to approve Minnesota's SIP.

While EPA now finds that "in light of more recent air quality analysis," Minnesota is linked to a single maintenance monitor in Illinois, this is based on information that did not exist at the time of Minnesota's SIP submission nor when EPA had a statutory obligation to approve the SIP. This was also not EPA's first use of untimely information to assess Minnesota's SIP. In 2022, EPA proposed to disapprove Minnesota's SIP "[s]ince new modeling ha[d] been performed by EPA with updated emission data," that EPA proposed "to primarily rely on … to identify nonattainment and maintenance receptors in 2023." Proposed Rule at 9867. As EPA acknowledged at the time, this was "a different method for projecting emissions" than what had been available to Minnesota for it to develop its SIP submittal. *Id.* EPA's repeated changes in emissions inventory and modeling platform after the deadline for SIP submissions and after Minnesota's SIP was deemed complete by EPA effectively moved the goalpost for Minnesota's SIP, undercutting the State of Minnesota's ability to identify the requirements EPA would apply to determine an approvable SIP.

The impact was significant. Minnesota's modeled impact went from contributing "below 1 percent of the NAAQS to receptors in 2023" to contributing "greater than 1 percent of the standards to two maintenance-only receptors in Illinois"[38] in the 2022 proposed SIP Disapproval

[37] SIP Disapproval at 9357.
[38] *Id.* at 9867-68.

to now being linked to one maintenance-only receptor in the 2023 SIP Disapproval (assuming no further adjustment for bias or data inaccuracies)). Notably, even using EPA's new data and modeling, Minnesota would still have had no linkage to a downwind maintenance receptor if EPA had not also moved the maximum threshold it indicated it would consider acceptable from 1 ppb to 1% (0.70 ppb).[39] As the D.C. Circuit has held, it is arbitrary and capricious to give states a "constantly moving target," *New York v. EPA*, 964 F.3d 1214, 1224 (D.C. Cir. 2020), let alone two. The language and structure of the Clean Air Act clearly give Minnesota and Petitioners the right to address this new data in the first instance in a SIP amendment, and not in a challenge to a SIP disapproval, as EPA now requires.

Notably, if EPA had followed the CAA procedures, it could have appropriately considered the new information it has developed since 2020, including the 2016v3 modeling it has introduced with the 2023 SIP Disapproval. But EPA cannot rely on its almost three year delay to circumvent the process and procedural protections set forth in the Clean Air Act. Rather, EPA was required to act on the SIP Minnesota submitted. If, after approval, EPA finds that a timely, complete and approved SIP nonetheless is "substantially inadequate … to mitigate adequately the interstate pollutant transport" or otherwise comply with the requirements of the Clean Air Act, "the Administrator shall require the State to revise the plan as necessary to correct such inadequacies." *Id.* at (k)(5). EPA also cannot simply disapprove the state's plan pending a new state submission that incorporated EPA's newly developed information, as the SIP Disapproval effectively does. In the event EPA finds a SIP Call is justified, EPA must first "notify the State of the inadequacies, and may establish reasonable deadlines (not to exceed 18 months after the date of such notice) for the submission of such plan revisions." *Id.* Further, "[s]uch findings and notice shall be public." *Id.* These procedural protections are an important component of the cooperative federalism embodied in the Clean Air Act. As courts have held, "[t]he Clean Air Act is an experiment in federalism, and the EPA may not run roughshod over the procedural prerogatives that the Act has reserved to the states, especially when … the agency is overriding state policy. *Bethlehem Steel Corp. v. Gorsuch*, 742 F.2d 1028, 1036–37 (7th Cir. 1984).

Multiple commenters, including the Minnesota Pollution Control Agency, have raised similar concerns arising from EPA's initial proposal to use 2016v2 modeling to disapprove state SIPs.[40] EPA has attempted to respond to those comments in the RTC, but in doing so, has not addressed the fundamental issue that EPA cannot disapprove a SIP that is approvable based on the information existing at the time that submittals are due, or even at the time EPA's SIP review was statutorily due, and cannot circumvent Minnesota's right to address new data in a SIP amendment, before EPA uses it to disapprove an otherwise approvable SIP. 42 U.S.C. §§ 7410(k)(3) and (5).

---

[39] Minnesota did not rely on the 1 ppb threshold for its SIP submission, but as EPA acknowledged, "[t]he 2018 modeling indicated the state was not projected to contribute above one 1 percent of the NAAQS to a projected downwind nonattainment or maintenance receptor. Therefore, the state may not have considered analyzing the reasonableness and appropriateness of a 1 ppb threshold at Step 2 of the 4-step Step interstate transport framework per the August 2018 memorandum." Proposed Rule at 9867.

[40] *See* RTC at 42-59.

EPA asserts in the SIP Disapproval that its use of new modeling and data did not move the goal post for states because EPA "did not evaluate states' SIP submissions based solely on the 2016v2 emissions platform (or the 2016v3 platform…)" but rather "evaluated the SIP submissions based on the merits of the arguments put forward in each SIP submission." SIP Disapproval at 9366. For Minnesota, however, EPA cites no basis or analysis for its SIP Disapproval other than the 2016v3 modeling results. Having relied on no other information to disapprove Minnesota's SIP, EPA cannot simply assert it had an additional basis with no additional substantiation. As the D.C. Circuit has noted, EPA cannot support its decision on only a "Delphic explanation of [Minnesota's] purported failure to carry its burden of proof." *New York*, 964 F.3d at 1224.

EPA also maintains that data and modeling it developed for the Proposed Rule in 2022, and now additional data and modeling it developed for the SIP Disapproval in 2023, supports a finding that Minnesota's SIP submission is "ultimately inadequate." SIP Disapproval at 9357. But even if this were the case, it does not give EPA a right to disapprove Minnesota's 2018 SIP. For data arising after EPA's statutory deadline to approve Minnesota's SIP, EPA could no longer rely on its obligation to use the "best information available." SIP Disapproval at 9366. Interpreting the Clean Air Act otherwise would not do justice to the cooperative federalism framework Congress established in CAA § 110, and would deprive states of important procedural protections allowing them to control and direct in the first instance, the implementation of the NAAQS within their borders.

The SIP Disapproval misapplies the D.C. Circuit's reasoning in *Wisconsin*, 903 F.3d at 322, when it asserts the SIP submission deadline is "'procedural'" and that to limit EPA's decision to information available at the time of the SIP submission or EPA's statutory review deadline would elevate it above requirements "'central to the regulatory scheme.'" SIP Disapproval at 9366 (quoting *Wisconsin*, 903 F.3d at 322. Neither *Wisconsin*, nor the case on which it relies, *Sierra Club v. EPA*, 294 F.3d 155 (D.C. Cir. 2002), addressed the issue presented here. In *Wisconsin*, the court was responding to an argument that EPA should have selected 2011 as its analytic year even though that year had already passed. In *Sierra Club*, the court was responding to a contention that EPA's ability to extend a SIP submittal deadline should support its authority to extend attainment deadlines. Here, EPA argues for an exception that would swallow the rule. If EPA could simply withhold ruling on a SIP until the State's information had become stale, and then disapprove the SIP and issue a FIP based on the "best available information," the cooperative federalism structure of the NAAQS would be an empty shell.

This is also not a situation like that which arose in *EME Homer City Generation, L.P. v. EPA,* 795 F.3d 118 (D.C. Cir. 2015). There, EPA had approved state SIPs in reliance on the Clean Air Interstate Rule ("CAIR"), which was subsequently found to have "more than several fatal flaws" by the D.C. Circuit. *North Carolina v. EPA*, 531 F.3d 896, 901 (D.C.Cir.2008) (*per curiam*). In addressing whether this ruling allowed EPA to "correct" its earlier SIP approvals under 42 U.S.C. § 7410(k)(6), the D.C. Circuit found EPA could do so, but only due to the unique circumstances of that case. *EME Homer City Generation*, 795 F.3d at 135 n.12 ("Our conclusion on Subsection 7410(k)(6) is limited to the unusual circumstances here, in which a federal court says that EPA lacked statutory authority at the time to approve a SIP."). Notably, the D.C. Circuit

did not decide whether EPA could rely on Clean Air Act §110(k)(6) to disapprove an approved SIP "in any other circumstances," and stated that its holding in particular "should not be read to diminish the scope or force of Subsection 7410(k)(5), which provides that whenever 'the Administrator finds that the applicable implementation plan for any area is substantially inadequate ... the Administrator shall require the State to revise the plan as necessary to correct such inadequacies.'" *Id.* (quoting 42 U.S.C. § 7410(k)(5)).

While in *EME Homer,* EPA had already approved several state SIPs, and in this rulemaking EPA has not yet approved Minnesota's SIP, this is a distinction without a difference. Minnesota submitted its SIP on October 1, 2018. It was deemed complete April 1, 2019.[41] EPA's period for review therefore ended April 1, 2020. As described in the Proposed Rule, Minnesota's SIP submission complied with the Clean Air Act and EPA's guidance for developing an interstate transport SIP for the 2015 ozone NAAQS. 87 Fed. Reg. at 9848-49. As detailed in the attached report, Alpine Geophysics' review confirms that Minnesota timely submitted an approvable SIP. By April 1, 2020, EPA had a statutory duty to approve Minnesota's SIP.

EPA's reliance on its 2016v3 modeling platform (which was not available to the public or interested parties) to reject the conclusions Minnesota reached based on the information that was available to all parties at the time is clearly of central relevance. Had EPA acted by its statutory deadline, Minnesota would have an approved SIP today. Further, while Petitioners have previously commented on the approvability of Minnesota's SIP, the basis for EPA's partial SIP Disapproval for Minnesota, including its decision to rely on its newer 2016v3 modeling platform, was not made public until the final rule. These grounds therefore arose after the close of the public comment period but before the time for judicial review. Reconsideration is therefore appropriate to address this procedural anomaly for Minnesota.

On reconsideration EPA should approve Minnesota's 2018 SIP based on the information that was available to EPA for its statutory review. The agency may then reassess whether, based on the information available today, including the above data and bias corrections, Minnesota's SIP remains sufficient to comply with prong 2 of the state's Good Neighbor obligations. For the reasons explained herein, EPA should find that the 2018 SIP was and is adequate to comply with prong 2.

III. Grounds for Stay of the SIP Disapproval

EPA has authority to stay the SIP Disapproval both pending reconsideration and pending judicial review. First, if the SIP Disapproval is subject to CAA § 307(d), a stay pending reconsideration can be granted for three months. Second, EPA has authority under the APA to stay the SIP Disapproval pending judicial review.

[41] *See* https://www3.epa.gov/airquality/urbanair/sipstatus/reports/mn_infrabypoll.html

A. A Stay Under CAA § 307(d)(7) is Appropriate.

The Clean Air Act provides that, if EPA grants reconsideration of a rule, "[t]he effectiveness of the rule may be stayed during such reconsideration…by the Administrator or the court for a period not to exceed three months." 42 U.S.C. § 7607(d)(7)(B). If the SIP Disapproval is subject to CAA § 307(d), a stay pending reconsideration is justified here.

EPA issued a final rule based primarily on emissions data and modeling that it did not make publicly available before issuance of the final rule. Even upon publication, EPA's release of data was partial and inadequate to reconstruct the modeling that EPA used for its final determinations. Obtaining the data and checking its accuracy has taken several weeks. It would take many more weeks to rerun EPA's modeling to confirm that the results support reversal of EPA's disapproval of prong 2 of Minnesota's SIP. It will likely take a similar amount of time to evaluate the evidence of bias Petitioners are submitting to confirm that it too, supports approval of Minnesota's SIP.

A stay will also not unduly impact downwind states. Minnesota is not modeled to interfere with attainment for any downwind state. Under EPA's most recent modeling, Minnesota is linked only to a single maintenance-only receptor, the most recent monitored design value of the monitor at this location was in attainment, and EPA's modeling for 2026 shows the receptor will model attainment as well with only minimal reductions from Minnesota. As EPA has itself emphasized, the SIP Disapproval does not require any action from the states.[42]

While a stay of the effective date of the SIP Disapproval for Minnesota would also prevent EPA from applying its FIP to Minnesota at the start of the upcoming ozone trading season, which is scheduled to start May 1, 2023, this is not likely to be relevant. In a recent filing, EPA has stated that the FIP is not likely to be effective until "late June to early July."[43] If EPA timely takes action on this reconsideration, this is well within the time EPA would need to conduct reconsideration. Further, while EPA has interpreted the CAA to require it "to address good neighbor obligations as expeditiously as practicable and no later than the next attainment date," RTC at 445, granting a stay of Minnesota's SIP denial pending reconsideration will not interfere with that goal. Minnesota is modeled to impact only a single maintenance-only monitor. As the D.C. Circuit has recognized, this 'may be a valid reason" to postpone addressing emission reductions until even after the next attainment date. *North Carolina v. EPA*, 531 F.3d 896, 912 (D.C. Cir. 2008). A reasonable stay to address reconsideration falls well within EPA's discretion.

B. EPA Should Stay the Effective Date of the SIP Disapproval Pending Judicial Review.

EPA can consider a stay of the entire SIP Disapproval for all affected states. Under the APA, EPA may stay the effective date of the SIP Disapproval pending judicial review when "justice

[42] *See, e.g.*, 2015 Ozone NAAQS Interstate Transport SIP Disapproval – Response to Comments ("RTC") at 466.
[43] Respondents' Consolidated Response in Opposition to the Motions for Stay of the Final Rule, *Texas v. EPA*, Case No. 23-60069, Doc. 109, at 12 (5th Cir. Filed March 27, 2023).

so requires." 5 U.S.C. § 705. Several Petitioners are filing a petition for judicial review of EPA's partial disapproval of Minnesota's SIP contemporaneously with this petition for reconsideration and stay. Multiple other petitions have already been filed for judicial review, including petitions by Arkansas, Kentucky, Oklahoma, Texas, Utah, and Wyoming. More are likely. These cases are already spread across four circuits, and additional litigation may expand the number of courts further.

The effective date of the SIP Disapproval is March 15, 2023. This effective date is significant for both legal and practical reasons. Legally, it will force EPA to promulgate a FIP within two years (though in this case EPA has already finalized its FIP). 42 U.S.C. § 7410(c)(1). States will also be required to prepare SIP revisions if they are interested in addressing the errors in EPA's analysis. Further, the significant legal flaws in EPA's SIP Disapproval discussed above, coupled with the technical and legal concerns it raises, make it likely that judicial review will result in a remand if not vacatur of the current SIP Disapproval. As a result, to avoid the unnecessary expenditure of EPA resources on a FIP, state resources on SIP revisions, and the resources of the public and regulatory industries in addressing a FIP that is likely to not be required, justice requires that the SIP Disapproval be stayed pending judicial review.

Further, while EPA is not bound to apply the same four-factor analysis used by courts for granting a judicial stay pending review, these factors indicate support for EPA in granting a stay of the SIP Disapproval. Under this standard, the considerations for a stay are:

(1) whether the stay applicant has made a strong showing that he is likely to succeed on the merits;

(2) whether the applicant will be irreparably injured absent a stay;

(3) whether issuance of the stay will substantially injure the other parties interested in the proceeding; and

(4) where the public interest lies.

Nken v. Holder, 556 U.S. 418, 434, 129 S.Ct. 1749, 173 L.Ed.2d 550 (2009) (citation omitted). These "four considerations are factors to be balanced and not prerequisites to be met." *State of Ohio ex rel. Celebrezze v. Nuclear Regul. Comm'n*, 812 F.2d 288, 290 (6th Cir. 1987).

1. Petitioners Have Made a Strong Showing They Are Likely to Succeed on the Merits

There is no fixed probability of success the agency must find in applying these considerations. "Ordinarily the party seeking a stay must show a strong or substantial likelihood of success. However, at a minimum the movant must show 'serious questions going to the merits and irreparable harm which decidedly outweighs any potential harm to the defendant if a [stay] is issued.'" *Id. (quoting In re DeLorean Motor Company*, 755 F.2d 1223, 1229 (6th Cir.1985)).

As discussed above, the SIP Disapproval has substantive and procedural flaws, each of which individually, and more so when combined, demonstrate "a high probability of success on the merits." *Ohio ex rel. Celebrezze v. Nuclear Regul. Comm'n.*, 812 F.2d 288, 290 (6th Cir.1987). Substantively, EPA's partial SIP Disapproval for Minnesota was based on an incorrect set of emissions data and biased modeling results that, when adjusted, support Minnesota's original conclusion that the state is not linked to downwind nonattainment or interference with maintenance and, even if linked, does not need to impose additional emission reductions to satisfy its Good Neighbor obligations. Procedurally, EPA did not follow the process required by the Clean Air Act for reviewing and approving Minnesota's SIP. In doing so, EPA deprived the State and Petitioners of the ability to address EPA's concerns in a SIP Call process.

Other flaws in the SIP Disapproval also strongly support a showing of likely success on the merits in a judicial challenge. In particular, we call to the agency's attention: (a) EPA's impermissible reliance on new data to disapprove prong 2 of Minnesota's SIP without providing adequate notice and an opportunity for public comment; and (b) the SIP Disapproval's subversion of the well-established and vital cooperative federalism underlying the entire Clean Air Act and in particular, the NAAQS.

a. *EPA Cannot Base its SIP Disapproval on Information that was Not Subject to Adequate Notice and Public Comment*

Under both the Administrative Procedure Act ("APA") and the CAA, EPA's rulemaking process requires adequate public notice and an opportunity to comment. *Small Ref.*, 705 F.2d at 547. This includes providing the public with the evidence on which EPA intends to rely. *Id.* at 540. Adding evidence on which EPA relies after the close of the comment period is "highly improper." *Id.* at 540; *see also Sierra Club*, 657 F.2d at 400 ("If … documents of central importance upon which EPA intended to rely had been entered on the docket too late for any meaningful public comment prior to promulgation, then both the structure and spirit of section 307 would have been violated."). Even reconsideration cannot cure an inadequate opportunity for notice and comment. *U. S. Steel v. EPA*, 595 F.2d 207, 214 (5th Cir. 1979) ("Permitting the submission of views after the effective date is no substitute for the right of interested persons to make their views known to the agency in time to influence the rulemaking process in a meaningful way.") (Internal quotations omitted).

In the SIP Disapproval, EPA "made a number of updates to [it's] inventories and model design to construct a 2016v3 emissions platform which was used to update [EPA's] air quality modeling." SIP Disapproval at 9339. The SIP Disapproval used "this updated modeling to inform [EPA's] final action on [Minnesota's] SIP submissions." *Id.* The details of these emissions inventory and modeling design changes were first described to the public in the SIP Disapproval and associated documents made publicly available the same day.[44] Even then, EPA did not make public its 2026 modeling results, reserving these for finalization of the FIP several weeks later.

[44] Even then, the supporting data and modeling platform were not made electronically available and needed to be requested by the public, which added several more weeks to gain access.

This data and modeling were clearly of central importance to EPA's disapproval of prong 2 of Minnesota's SIP. In fact, they are the sole basis for EPA's disapproval. *See* SIP disapproval at 9357 (finding Minnesota's analysis "ultimately inadequate" in light of EPA's "more recent air quality analysis"); *see also id*. (disapproving prong 2 of Minnesota's SIP because "[i]n the 2016v3 modeling, Minnesota is projected to be linked above 1 percent of the NAAQS to one maintenance-only receptor"). As a result, EPA was required to provide the public advance notice of its new data and an opportunity for meaningful public comment.

EPA's publication of its revised emissions inventory and modeling the day of the SIP Disapproval did not satisfy this requirement. In *Kennecott Corp. v. EPA*, 684 F.2d 1007, 1019 (D.C. Cir. 1982), the D.C. Circuit found EPA had not provided adequate opportunity for public comment on economic modeling placed in the docket only one week before promulgation of its final regulations. Here, EPA did not make its new emissions data and modeling publicly available until the *day* it published its final SIP Disapproval.

It is not enough to say that Petitioners had the opportunity to comment on EPA's previous version of the emissions data and modeling, or that EPA's latest data simply "incorporates comments generated during the public comment period." SIP Disapproval at 9366. As the D.C. Circuit stated in *Chesapeake*, 952 F.3d at 320, it would be an "unreasonable burden on commenters not only to identify errors in a proposed rule but also to contemplate why every theoretical course of correction the agency might pursue would be inappropriate or incorrect." The new data and modeling on which EPA relies for the SIP Disapproval differs significantly from that which was in the public record. Based on EPA's own summary of the data, Minnesota's largest contribution to a downwind maintenance receptor changed from 0.97 ppb to 0.85 ppb based on EPA's changes. *Compare* Proposed Rule at 9868 *with* SIP Disapproval at 9354. Since EPA's own adopted significant contribution threshold in the SIP Disapproval is 0.7 ppb, a change of 0.12 ppb is clearly significant.[45]

Under both the CAA and the APA, EPA was required to provide notice and an opportunity for public comment on its 2016v3 data. There is no question that EPA provided no notice or opportunity for comment. As a result, there is a high likelihood that Petitioners would be likely to prevail on the merits of a judicial challenge. This strongly supports EPA issuing a stay of the effective date of the SIP Disapproval pending judicial review.

b. *EPA Undermined State Primacy by Disapproving Minnesota's SIP Despite its Adherence to the Requirements of the Clean Air Act.*

As EPA acknowledges, "[t]he CAA establishes a framework for state-Federal partnership to implement the NAAQS based on 'cooperative federalism.'" SIP Disapproval at 9367. Under this model, "the Federal Government establishes broad standards or goals, states are given the

---

[45] EPA's 2016v3 modeling did not just result in significant changes to EPA's assessment of Minnesota's potential impact on downwind states. Six states (Arizona, Iowa, Kansas, New Mexico, Tennessee, and Wyoming) had their status as linked states change entirely. *See* Air Quality Modeling Technical Support Document 2015 Ozone NAAQS SIP Disapproval Final Action, https://www.regulations.gov/document/EPA-HQ-OAR-2021-0663-0017 at 24.

opportunity to determine how they wish to achieve those goals, and if states choose not to or fail to adequately implement programs to achieve those goals, a Federal agency is empowered to directly regulate to achieve the necessary ends." *Id.* Thus, "states have the obligation and opportunity in the first instance to develop an implementation plan to achieve the NAAQS under CAA section 110" and "EPA will approve SIP submissions under CAA section 110 that fully satisfy the requirements of the CAA." *Id.* As the Supreme Court has held: "[e]ach State is given wide discretion in formulating its plan, and the Act provides that the Administrator 'shall approve' the proposed plan if it has been adopted after public notice and hearing and if it meets [the CAA's] criteria." *Union Elec. Co. v. EPA*, 427 U.S. 246, 250 (1976) (*quoting* 42 U.S.C. § 7410(a)(2)).

EPA departed from this framework when it proposed a SIP disapproval based, not on any inaccuracy in Minnesota's evaluation of the data, but on EPA's preference for a different modeling platform and emissions inventory. EPA does not have the authority to condition SIP approval on the state's adoption of EPA's preferred approach, or to supplant Minnesota' interpretation of how best to achieve the goals of the CAA, as long as Minnesota complies with the requirements of the CAA.

EPA's position is predicated on an incorrect summary of its role in the SIP review process and the relevant case law. First, EPA's role is not "secondary" only in that "it occurs second in time." RTC at 425 (internal quotations omitted). EPA relies on *EPA v. EME Homer City Generation*, LP, 572 U.S. 489 (2014) for this proposition, but the case does not support EPA's position. It must be remembered that *EME Homer* involved EPA's authority to promulgate a FIP after EPA had already disapproved SIPs.[46] As a result, the Court did not address EPA's statutory duty to approve a timely and complete SIP submission, which is the issue here. The Court's "interpretations of CAA section 110(a)(2)(D)(i)(I)" on which EPA relies must be read in this light. RTC at 426. The Court upheld interpretive choices EPA made when issuing a FIP. The Court did not say EPA could delay approval until new information became available that supported its disapproval of the SIP.

Second, EPA is wrong to imply that *EME Homer* undermines the long line of cases setting out EPA's secondary (in substance, not just in time) role in developing plans to implement the NAAQS. In fact, the Supreme Court continues to cite these cases for their interpretation of EPA's role. *See West Virginia v. EPA*, 213 L. Ed. 2d 896, 142 S. Ct. 2587, 2600 (2022) ("EPA … does not choose which sources must reduce their pollution and by how much to meet the ambient pollution target. Instead, Section 110 of the Act leaves that task in the first instance to the States, requiring each 'to submit to [EPA] a plan designed to implement and maintain such standards

[46] *See EME Homer*, 572 U.S. at 507 ("The gravamen of the State respondents' challenge ***is not that EPA's disapproval of any particular SIP was erroneous***. Rather, respondents urge that, notwithstanding these disapprovals, the Agency was obliged to grant an upwind State a second opportunity to promulgate adequate SIPs once EPA set the State's emission budget. ***This claim does not depend on the validity of the prior SIP disapprovals***. Even assuming the legitimacy of those disapprovals, the question remains whether EPA was required to do more than disapprove a SIP, as the State respondents urge, to trigger the Agency's statutory authority to issue a FIP.") (emphasis added).

within its boundaries.'") (*quoting Train v. Natural Resources Defense Council, Inc.*, 421 U.S. 60, 65 (1975)).

The SIP Disapproval and RTC makes clear that EPA's disapproval of prong 2 of Minnesota's SIP was not based on a determination that Minnesota's SIP failed to meet the statutory requirements of CAA, but because EPA wanted to apply "a consistent set of policy judgments across all states for purposes of evaluating interstate transport obligations and the approvability of interstate transport SIP submissions for the 2015 ozone NAAQS under CAA section 110(a)(2)(D)(i)(I)." SIP Disapproval at 9339; *see also id.* at 9340 ("Effective policy solutions to the problem of interstate ozone transport going back to the NOx SIP Call have necessitated the application of a uniform framework of policy judgments to ensure an 'efficient and equitable' approach.") (quoting *EME Homer*, 572 U.S. at 519); RTC at 425-426. This was error. EPA's assessment of a SIP is to be based on whether the SIP compiles with the requirements of the CAA, not on EPA's policy preferences or desire for efficiency. Only after a state fails to comply with its statutory requirements can EPA impose what it believes best to achieve the substantive objective of the Act.

Because EPA's SIP Disapproval is based on improper factors that undermine the core cooperative federalism embodied in CAA § 110, Petitioners are likely to prevail on the merits of a judicial challenge. This further supports EPA issuing a stay of the effective date of the SIP Disapproval pending judicial review.

2. Petitioners Will Suffer Irreparable Harm from a Denial of Stay.

Relevant factors for evaluating the harm which will occur include: (1) the substantiality of the injury alleged; (2) the likelihood of its occurrence; and (3) the adequacy of the proof provided. In evaluating the harm which will occur both if the stay is issued and if it is not, the court must look to three factors: the substantiality of the injury alleged, the likelihood of its occurrence, and the adequacy of the proof provided. *Ohio ex re. Celebrezze*, 812 F.2d at 290 (*citing Cuomo v. United States Nuclear Regulatory Commission*, 772 F.2d 972, 974 (D.C.Cir.1985)).

The SIP Disapproval poses substantial and imminent injuries to Petitioners. As discussed in Section II above, the data which EPA should have used to evaluate Minnesota's SIP (see Section II.C), the best available data today, when flaws are addressed (see Sections II.A and B), and even the most likely future data (see Section II.D) strongly support a finding that Minnesota is not significantly contributing to nonattainment or interfering with maintenance of the 2015 ozone NAAQS in any state. EPA's SIP denial is predicated on the erroneous conclusion that there *is* interference with maintenance. This places the entire State of Minnesota in an erroneous state of non-compliance with the Good Neighbor requirement of the Clean Air Act.

EPA's SIP Disapproval also forces EPA to promulgate emission reductions through a FIP. 42 U.S.C. § 7410(c). EPA has already finalized just such a rulemaking. This leaves no time for reconsideration or judicial review to run its course before Petitioners are injured by the FIP, let alone time for Minnesota to remedy EPA's issues with the submitted SIP. Petitioners submitted detailed comments on the FIP identifying numerous substantial injuries from EPA's promulgation

of its Proposed FIP that are likely to occur, and supported by substantial evidence, including detailed technical reports.[47] While EPA made substantial modification to the FIP in response to comments, which Petitioners appreciate reflects considerable work on the Agency's part following the public comment period and has addressed many significant issues with the proposed FIP, the final FIP nonetheless includes significant obligations for Petitioners' electric generating units ("EGUs"), starting in the current 2023 ozone trading season (which begins this year). Even Petitioners without EGUs are substantial consumers of electricity, meaning that they will likely bear much of the burden of the higher costs needlessly imposed on Minnesota power producers because of the FIP. Further, while the Proposed FIP is a separate rulemaking, EPA has itself identified the SIP Disapproval as both a necessary step in issuance of a final FIP[48] and the stay of a SIP disapproval that is the basis for a FIP is an appropriate remedy for injuries arising from the FIP itself. *See EME Homer City Generation, L.P. v. EPA*, 696 F.3d 7, 44 n.6 (D.C. Cir. 2012) (Rogers, J., dissenting), *rev'd on other grounds,* 572 U.S. 489 (2014) ("If [states] wish to avoid enforcement of the Transport Rule FIPs because they contend EPA's SIP disapprovals were in error, the proper course is to seek a stay of EPA's disapprovals in their pending cases; if granted, a stay would eliminate the basis upon which EPA may impose FIPs on those States.") (citing 42 U.S.C. § 7410(c)(1)(B)).

3. Staying the SIP Disapproval will not Significantly Injure Other Parties.

As discussed in Section III.A above, the SIP Disapproval does not on its own impose any emission reductions on sources. As a result, a stay will not directly harm any other party. While a stay would also potentially delay the effective date of the FIP, this is unlikely to result in significant injury to other parties. EPA has recently extended a judicially-enforceable deadline to review Good Neighbor SIPs for three states to December 15, 2023 without any mention of public harm from the delay.[49] Even as a stepping stone to a FIP, while a stay will alleviate imminent and irreparable costs, it will not significantly impact NOx emissions. As discussed above, the FIP is unlikely to be effective until after the start of the current ozone trading season, resulting in an attenuated impact on 2023 emissions. Further, even if projected emission reductions for the full 2023 ozone trading season could be achieved, EPA projects total emission reductions from Minnesota of only 139 tons in 2023. This is unlikely to result in any significant impact on the Cook County maintenance monitor.

4. The Public Interest Lies in Granting a Stay.

As courts have held, there is a public interest enjoining inequitable conduct and in minimizing unnecessary costs to be met from public coffers. *See, e.g. B & D Land & Livestock Co. v. Conner*, 534 F. Supp. 2d 891, 910 (N.D. Iowa 2008). Here, the public interest supports a stay.

[47] See Comments of U. S. Steel, EPA-HQ-OAR-2021-0668-0798 (June 27, 2022); Comments of Xcel Energy, EPA-HQ-OAR-2021-0668-0411 (June 23, 2022); Comments of Minnesota Power, EPA-HQ-OAR-2021-0668-0539 (June 23, 2022); Comments of SMMPA, EPA-HQ-OAR-2021-0668-0351 (June 22, 2022); Comments of Cleveland-Cliffs Inc., EPA-HQ-OAR-2021-0668-0405 (June 23, 2022)

[48] 88 Fed. Reg. 9336 at 9362.

[49] *See* Joint Notice of Second Stipulated Extension of Consent Decree Deadlines, Doc. 33, *Downwinders at Risk v. Regan*, Case No. 4:21-cv-3551-DMR (N.D. Cal. Jan. 30, 2023).

As discussed in Section II.A above, EPA's SIP Disapproval was promulgated through the inequitable exclusion of public participation into the data central to EPA's final rulemaking. The result will be costly public expenditures, both by EPA to promulgate an unnecessary FIP and States to either prepare to implement EPA's FIP or prepare revised SIPs, and well as unnecessary costs borne by Petitioners.

While it was an error for EPA to disapprove Minnesota's SIP based on information not in the record at the time of submission, EPA can ameliorate the harm of this error by staying the effect of its SIP disapproval until the merits of the issues above can be fully evaluated and addressed.

IV. Conclusion

The State of Minnesota has expended substantial effort and resources to regulate the emission of NOx within its borders. Those efforts have successfully reduced State impacts on downwind receptors to a point that Minnesota is not a significant contributor to nonattainment or interference with maintenance of the 2015 ozone standard in any state. Based on the best available data and modeling science available at the time, Minnesota assessed its impact on downwind states, as it was required to do under the Clean Air Act, and appropriately concluded that it was not interfering with maintenance of attainment in any state. EPA has identified no error or omission in Minnesota's analysis. Nonetheless, based on data that was not available at the time, and in fact was not available to the public until February 2023, EPA partially disapproved Minnesota's Good Neighbor plan for the sole reason that, based on EPA's own modeling, it found a single maintenance receptor in Cook County, Illinois that Minnesota state emissions were impacting at a maximum level of 0.85 ppb. Neither Minnesota, nor Petitioners, were given an opportunity to comment on EPA's modeling, fully evaluate it, or even see it, until EPA published its final SIP Disapproval. While a complete analysis of EPA's modeling would require months, based on Petitioners' review of the data specific to them, and based on expert evaluations by Alpine Geophysics of the modeling and data EPA has provided, EPA's results likely overstate the impact Minnesota is having on the Cook County monitor. Because Petitioners have provided new information that reveals flaws in EPA's emissions inventory for Minnesota and bias in EPA's modeling of the lone monitor that links Minnesota emissions to a downwind state, Petitioners have raised material new data undermining the central basis for EPA's disapproval of prong 2 of Minnesota's SIP. Petitioners therefore request that EPA grant reconsideration of its partial SIP disapproval for Minnesota and approve Minnesota's 2018 SIP. Further, to avoid the significant and irreparable harm to Petitions arising from EPA's erroneous disapproval of prong 2 of Minnesota's SIP, EPA should stay the effectiveness of its SIP Disapproval as applied to prong 2 of Minnesota's SIP pending reconsideration and pending judicial review.

Alpine Geophysics, LLC -- 387 Pollard Mine Road -- Burnsville, NC 28714 -- (828) 675-9045

DOCUMENT OBJECTIVE

The objective of this document is for Alpine Geophysics, LLC to provide technical review and professional opinion of Minnesota Pollution Control Agency's (MPCA) SIP revision to address Clean Air Act (CAA) Section 110(a)(2)(D)(i)(I) and the Environmental Protection Agency's (EPA) final action to disapprove the Minnesota State Implementation Plan (SIP) published on February 13, 2023 in the Federal Register.

This document is formatted into three sections that discuss our review and assessment of the following issues:

A. Whether, given time to reassess, MPCA could demonstrate no linkage and/or no significant impact on attainment and maintenance in downwind states;
B. Whether U.S. EPA's revisions to its modeling approach since MPCA's SIP submittal were ancillary; and
C. Whether the Minnesota Pollution Control Agency's state implementation plan revision was approvable based on the state of the science at the time it was submitted to U.S. EPA.

At the end of this document, we also provide a summary of conclusions (Section D) and a regulatory and legislative timeline of actions taken on Minnesota's 2015 ozone SIP for reference (Section E).

A. Given time to reassess, MPCA could demonstrate no linkage and/or no significant impact on attainment and maintenance in downwind states.

EPA provided little time for MPCA to review the significant amount of technical information and associated calculations that were used to justify their disapproval of the Minnesota SIP, especially since EPA used a distinct and largely unrelated modeling platform, emissions inventory, and air quality model to justify its action instead of assessing the platform submitted by MPCA in support of its SIP. Notwithstanding the fact that four years and four months passed since the original Minnesota SIP was submitted to EPA, had appropriate time been given to MPCA to review and address EPA's final disapproval, MPCA could have addressed significant flaws in EPA's modeling that EPA itself should have addressed prior to finalizing any SIP disapproval.

It is our opinion that the U.S. EPA should have approved the MPCA's SIP when it was submitted in 2018. However, since EPA has put forward new modeling, we have reviewed this modeling and found several issues with the emissions that EPA used in the new modeling that weigh against using it as a basis for disapproving the Minnesota SIP.

1. EPA inappropriately revised the emission inventory and conducted new air quality modeling for SIP disapprovals without allowing a meaningful opportunity for stakeholder review and comment.

EPA's revisions to the emission inventory used in the modeling it previously has conducted for historic transport rules raises an administrative concern about public review and comment.

EPA notes in the proposed SIP disapprovals that, after the modeling it conducted in support of earlier transport rules, e.g., CAIR, CSAPR, CSAPR Update, CSAPR Closeout, and Revised CSAPR Update, the agency revised the emission inventory used in the modeling to assess the efficacy of prior transport rules. EPA conducted new modeling using this revised inventory and 2016v2 modeling platform. The agency describes the process as follows:

> *Following the Revised CSAPR Update final rule, the EPA made further updates to the 2016 emissions platform to include mobile emissions from the EPA's Motor Vehicle Emission Simulator MOVES3 model and updated emissions projections for electric generating units (EGUs) that reflect the emissions reductions from the Revised CSAPR Update, recent information on plant closures, and other sector trends. The construct of*

> *the updated emissions platform, 2016v2, is described in the emissions modeling technical support document (TSD) for this proposed rule.*[1]

In December 2021, and in response to EPA requests for inventory review and updates[2,3,4], MPCA and other stakeholders submitted detailed comments on the 2016v2 emission inventory platform to correct errors that existed in that platform. EPA's declared efforts to revise this emission inventory platform at this time raised the question about whether EPA intended to update the modeling that has been used as the basis for the SIP disapprovals and the proposed FIP – but only in support of the final rule. EPA's own summary[5] of the comment process includes the statement that "by spring of 2021 it was necessary to make updates to the inventories to perform credible / defensible modeling in CY2021". In this summary, numerous and significant emission, control, and projection factor changes were requested and only with release of the final SIP denials were the changes shared by EPA for review.

As part of these comments, MPCA submitted comments on the 2016v2 emissions modeling platform (EMP) relative to three areas of improvement within Minnesota:

1. Non-electricity generation stationary (non-EGU) point source emissions controls
2. Future year emissions projections for various point and non-point inventory sectors
3. Stationary point EGU growth rate differences between the ERTAC vs IPM models

Non-EGU point source emissions controls

LADCO worked with member states to identify the highest-emitting sources and applicable control technology information for non-EGU stationary point sources in the region. They generated a spreadsheet with the highest-emitting non-EGU sources in 2016 for each LADCO state, including Minnesota, which also included state updates on emissions control information for listed sources.

A provided spreadsheet identified control information and future emission rate changes for several Minnesota sources within the 2016v2 EMP. The control information identified accounts for the installation of low NOx burners at the taconite facilities in Minnesota as part of the Regional Haze Taconite FIP. Based on MPCA estimates, just under 11,000 tpy in NOx reductions were expected due to the controls required by the Taconite FIP. MPCA noted the importance of

having these significant reductions included in the EPA EMP for non-EGUs and requested that EPA do so.

Below is a summary of approximate NOx emission changes for these sources.

- 2,100 tpy at Minorca Mine
- 2,300 tpy at Hibbing Taconite
- 700 tpy at United Taconite
- 3,600 tpy at US Steel Keetac
- 2,100 tpy at US Steel Minntac

Future year emissions projections for various point and non-point inventory sectors

LADCO used US EPA-generated emissions projection reports and identified a list of SCCs that they believed had incorrect future year projection rates. The 2016v2 EMP projection rates were not found consistent either with real-world emissions trends or regional emissions projection information. It was requested that EPA replace the 2016v2 EMP projections for these sources with the updated rates provided by LADCO.

A spreadsheet was provided that included the list of the SCCs with alternative projection information and LADCO comments on the sources of the alternative information.

Stationary point EGU growth rate differences between the ERTAC vs IPM models

LADCO recognized that EPA used the Integrated Planning Model (IPM) to estimate future year EGU emissions, and that the IPM projection methodology differed from the Eastern Research Technical Advisory Committee (ERTAC) EGU model that is endorsed by the MJOs and most of the states in the eastern half of the country. Minnesota noted support for the use of ERTAC EGU projections in the 2016v2 EMP and asked EPA to consider replacing IPM projections with ERTAC EGU projections for sources in the LADCO region in subsequent modeling platforms.

While most states urged EPA to rely on modeling that accurately reflects current on-the-books regulatory requirements and up-to-date emission inventories, they also strenuously object to the possibility that EPA would conduct any such additional modeling to support a final rule. Furthermore, these states object to EPA not providing the opportunity for those data to be reviewed, analyzed, commented upon, and having those comments addressed by EPA in advance of any final decision on the subject SIP disapproval (or for that matter the related FIP). These concerns were also expressed in July 2021 by several MJOs (WESTAR, LADCO, SESARM, MARAMA, and CENSARA).[6]

[6] https://www.regulations.gov/comment/EPA-HQ-OGC-2021-0692-0012

EPA's Previously Unreleased 2016v3 Modeling Platform

EPA's newest emissions inventory and modeling platform are of central relevance to EPA's final rule. The SIP Disapproval itself identifies EPA's "updates to the 2016v2 inventories and model design to construct a 2016v3 emissions platform which was used to update the air quality modeling" and used "this updated modeling to inform its final action on these SIP submissions.[7]" These data and modeling in fact form the basis for EPA's final disapproval of Minnesota's SIP[8] (finding Minnesota's analysis "ultimately inadequate" in light of EPA's "more recent air quality analysis"). This issue also arose only with the publication of the final SIP Disapproval. EPA's publication of its revised emissions inventory and modeling did not occur until then, and states had no access to the data, the modeling, or even the results of EPA's modeling until that time.

In the limited time that states have had with the modeling data, significant errors have been identified. A robust public comment process for these data is necessary to correct all significant errors to ensure that EPA's regulatory decisions are based on valid and accurate information. Within Minnesota alone, some of these errors include the following:

- EPA incorrectly included NOx emissions of 2,822 tons in 2023 for Northshore Mining Co. – Silver Bay in the future year air quality modeling and associated significant contribution calculations but not in the engineering analysis used to calculate state level EGU budgets. The subject boilers have been idled since October 2019 and are expected to have zero emissions in 2023;

- EPA predicts zero emissions at Minnesota Power's Laskin Energy Center units that have been converted to natural gas and expect continued MISO dispatch to support the renewables transition and regional grid needs / constraints;

These errors, and many like these presumed in other states in the modeling platform, may significantly impact the results of EPA's analysis and could be the difference in nonattainment and maintenance determinations or whether Minnesota is having a downwind effect on the lone Illinois maintenance monitor that subjects Minnesota to the Good Neighbor provisions of the Clean Air Act.

It is our opinion that the absence of inclusion of Minnesota's and other stakeholder's valid EMP revision submissions, as requested by EPA, and without a rerun of the air quality model in both the base and projection year simulations, EPA cannot appropriately identify monitors as nonattainment or maintenance, and in turn, cannot calculate upwind state significant contribution metrics from these same data. Non-EGU emission controls and their associated NOx emission reductions as documented and submitted by MPCA, could be enough to change

[7] 88 FR 9339
[8] 88 FR 9357

nonattainment designations and linked significance using an updated platform, and needs to be considered before making any final decision on denial of MPCA's SIP.

2. The Cook County, Illinois monitor to which Minnesota is linked, is located at the interface of land and water along Lake Michigan and is not properly characterized by EPA's supporting modeling.

EPA did not make a bias adjustment for the only receptor that EPA found "links" Minnesota to downwind interference with maintenance. Observed values at this location (the Alsip/Village Garage monitor) demonstrate significant model overprediction, justifying the need for adjustments to address bias. While EPA has recently investigated bias in southern Lake Michigan, this assessment selectively analyzed only one monitor, which was not representative of the bias observed at the Village Garage monitor. The failue to adequately address bias in EPA's modeling resulted in an overprediction of ozone. Adjusting for this bias supports the conclusion that the Alsip monitor models in attainment of the 2015 ozone NAAQS and therefore Minnesota is not interfering with maintenance at this monitor. EPA's ozone attainment modeling guidance states that:

> *"[t]he most important factor to consider when establishing grid cell size is model response to emissions controls. Analysis of ambient data, sensitivity modeling, and past modeling results can be used to evaluate the expected response to emissions controls at various horizontal resolutions for both ozone and PM2.5 and regional haze. If model response is expected to be different (and presumably more accurate) at higher resolution, then higher resolution modeling should be considered. If model response is expected to be similar at both high and low(er) resolution, then high resolution modeling may not be necessary. The use of grid resolution finer than 12 km would generally be more appropriate for areas with a combination of complex meteorology, strong gradients in emissions sources, and/or land-water interfaces in or near the nonattainment area(s)"*

EPA's modeling in support of the SIP disapprovals simulated a national domain using a 12km grid resolution domain wide. While this makes running a national, regional simulation easier from a technical perspective, it neglects the important issue of the complex meteorology and/or land-water interfaces in or near the nonattainment or maintenance monitors of interest. Indeed, EPA's choice of a 12km grid is an arbitrary choice in contravention of its own guidance when modeling Illinois monitors in Cook County because these monitors are at land-water interfaces.

Photochemical modeling along coastlines is complex for two reasons. First, the temperature gradients along land/water interfaces can lead to localized on-shore/off-shore flows; and

secondly, the photochemical model formulation spreads the emissions in a grid cell throughout the full grid volume of the cell.

Figure 1 presents a unique area along Lake Michigan that is challenged by these complex meteorologic issues at land-water interfaces. For the Cook County, Illinois monitor with which Minnesota is linked in this final rule, EPA's published model performance evaluation (MPE) metrics for ozone have been reviewed by Alpine on a day-specific basis.

Figure 1. Lake Michigan shoreline monitors located on land/water interface in Illinois.

Studies indicate that air quality forecast models typically predict large summertime ozone abundances over water relative to land and that meteorology around Lake Michigan is distinctly unique; both shortcomings warrant individualized attention and a finer grid resolution to best explore actual conditions.[9,10,11]

The 3x3 neighborhood of grid cells used in determining the design values of the relative response factor (RRF) at land-water interface monitors extends into the noted water bodies. Under current guidance, the top ten modeled days within this 3x3 matrix are used in determining this RRF for each monitor with any cell identified as 50 percent or more water, except for cells including monitors, which are omitted from the calculations.

Table 1 below provides a list of top 10 days at monitor 170310001 (Alsip/Village Garage), the Cook County monitor in Illinois to which Minnesota is linked, and comparisons of daily modeled

maximum daily average 8-hour ozone concentrations (highlighted in green) and observations on the same date in 2016 (highlighted in blue). These are the dates selected in EPA's modeling to represent the highest modeled days used in estimating future year design values.

As can be seen in Table 1 below, several days selected for RRF calculation have modeled ozone concentrations that fall outside of normally acceptable normalized bias (NBias) boundaries (±15%), here as the result of over (positive bias) predictions compared to observed concentrations on those days. In fact, at the monitor example below, seven of the ten selected days fall outside of the ±15% bias metric (highlighted in orange in the Table) with a maximum normalized bias of 93.60% (observation was 45.25 ppb and modeled concentration was 87.60 ppb; a difference of over 42 ppb).

When these dates are used, EPA's calculation of future year DV is 68.2 ppb (average) and 71.9 ppb (maximum) using the average RRF of 0.9349, identifying this as a maintenance monitor.

	Average	**Maximum**
Modeled 2016 DV (ppb)	73.0	77.0
Average RRF	0.922	0.922
Future 2023 DV (ppb)	67.3	70.9

Table 2. Alternate bias adjusted list of top 10 days at the Alsip/Village Garage monitor (170310001) in Illinois used in RRF and resulting calculated design values (ppb).

As a result of this bias adjusted calculation, the Alsip / Village Garage monitor located in Cook County, Illinois (170310001) has an average RRF of 0.922, resulting in an average 2023 DV of 67.3 ppb and a maximum DV of 70.9 ppb, identifying this monitor as attainment of the 2015 ozone NAAQS.

Under Step 1 of the ozone transport framework established by EPA, this monitor would not be considered as part of the list of receptors in the significant contribution calculation and therefore any linkages from upwind state contributions would be irrelevant.

Since this is the only monitor in which Minnesota is linked as a significant contributor under EPA's modeling, this linkage would be broken, and Minnesota should be removed from the list of contributing states to downwind receptors.

In the Response to Comments document from the rule, EPA attempted to address the bias issue by preparing an analysis at select monitors in the modeling domain. Specifically, EPA notes[12] that,

> *"Even though the EPA disagrees with commenter's assertion to "throw out" specific days at individual monitors for which model performance does not meet the criteria, out of an abundance of caution, the EPA performed a sensitivity analysis for selected receptors in which the projected 2023 DVs and contributions were recalculated after removing individual days that fell outside the Emery et al., criteria for normalized mean bias and/or normalized mean error. The EPA chose receptors in Coastal Connecticut, the Lake Michigan area, Dallas, and Denver for this analysis. The specific receptors included in this sensitivity analysis are Stratford, Connecticut, Chicago/Evanston, Illinois, Dallas/Denton, Texas, and Denver/Rocky Flats, Colorado."* (emphasis added)

While we agree with EPA's technical approach and calculations in their Chicago/Evanston example provided, EPA's selection of the Evanston monitor is questionable as it is the only monitor out of ten in Cook County, Illinois (three which are identified as maintenance) where performance-based recalculation results in higher design values. This is also not the unique, individual monitor to which Minnesota is exclusively linked. Table 3 presents the ten Cook County, Illinois monitors in EPA's modeling results[13].

As presented in Table 2, using bias-adjusted design values for the individual receptor with which Minnesota is linked (170310001), this monitor is calculated to be in attainment of the 2015 ozone NAAQS in 2023. This decrease is also seen in the remaining Cook County monitors that EPA did not consider in its response to comments on the issue.

Table 3. Future year design values (ppb) and significant contribution calculations of upwind states to monitors in Cook County, Illinois.

Table 4 demonstrates that the Evanston monitor (170317002) in which EPA used to illustrate a noted increase in design value calculations using a bias adjustment calculation was the only monitor out of the ten where the average and maximum design values increased. Had EPA selected any other monitor from Cook County to demonstrate the bias adjustment, their conclusion may have been different than presented in the Response to Comment document.

Table 4. EPA final rule and bias-adjusted future year design values (ppb) of monitors in Cook County, Illinois.

Additionally, the LMOS 2017 study[14] shows that for Lake Michigan coastal monitors the air quality model even at a 4 km resolution does not simulate the proper timing and structure of the land/lake breeze or the inland penetration of elevated ozone concentrations. A review of this LMOS study[15] states "To reproduce the timing and magnitude of the ozone time series at coastal monitors, ozone production over the lake must be correctly simulated; furthermore, details of the lake breeze must be accurate——timing, horizontal extent, and vertical structure." Based on recommendations from the LMOS 2017 study research team, a horizontal resolution of at most 1.3 km is required to reasonably resolve the complex meteorology of the air/water interface for the great lakes and coastal ocean areas. The LMOS 2017 Study researchers believe that a 1.3 km grid spacing will assist in the resolution of the large ozone concentration gradients that often occur along the shoreline as well as the inland penetration of the lake breeze circulation.

As the Alsip / Village Garage example shows, days where modeled ozone was predicted at concentrations differing up to ± 42 ppb are being used to estimate future year ozone concentrations and to make determinations of nonattainment, maintenance, and significant contribution from upwind sources.

Furthermore, to adequately capture the inland penetration of the lake breeze, the LMOS report also cites the need for accurate Lake Michigan water temperatures and correct model physics options. EPA's use of the Pleim-Xiu Land Service Model (LSM) does not adequately capture the lake breeze inland penetration. A review of wind vector observations (from the Meteorological Assimilation Data Ingest System (MADIS) network) compared to modeled wind vectors on RRF and significantly contributing days at nonattainment monitors highlights the differences in wind direction and speed during many hours of these predicted high ozone episodes.

On many days with relatively simple meteorology, EPA-developed wind fields using the Weather Research and Forecasting (WRF) Model agree with the MADIS observed winds. However, the modeled winds have strong disagreement with the observed meteorology on June 15, July 7, July 27 and August 4, 2016, the four days when the CAMx model predicted the highest ozone concentrations and are thus used in estimating RRFs and future year ozone design values. The following presents an example on August 4, 2016, a day within the top ten highest model estimated MDA8 ozone concentrations at the Alsip / Village Garage monitor.

[15] Stanier, C. O., & et al. (2021, November). Overview of the Lake Michigan Ozone Study 2017. BAMS, 19.

In Figure 2 below, the black wind vectors are the wind fields used in the CAMx model. For clarity only every third grid cell is presented. The red vectors are the hourly observed wind vectors from the MADIS archive. The hourly results from 1300 CDT through 1600 CDT are presented in these Figures. The observations clearly show a broad persistent land to lake flow along the western shoreline while the model shows a persistent lake to land flow in this same region during this same period. For this timeframe, when the model is estimating the highest ozone for the ozone season at this receptor, the model has the winds flowing from the lake to the shore while the observations are winds flowing from the shore to the lake.

Figure 2 demonstrates that observed winds (red arrows) are seen moving from land to lake along the western shoreline of Lake Michigan, typically associated with clearing events and lower ozone levels in areas in and around Chicago. In contrast, the model (black arrows) shows a lake to land flow, typically associated with higher model predicted ozone concentrations due to the higher reactive photochemistry over water bodies.

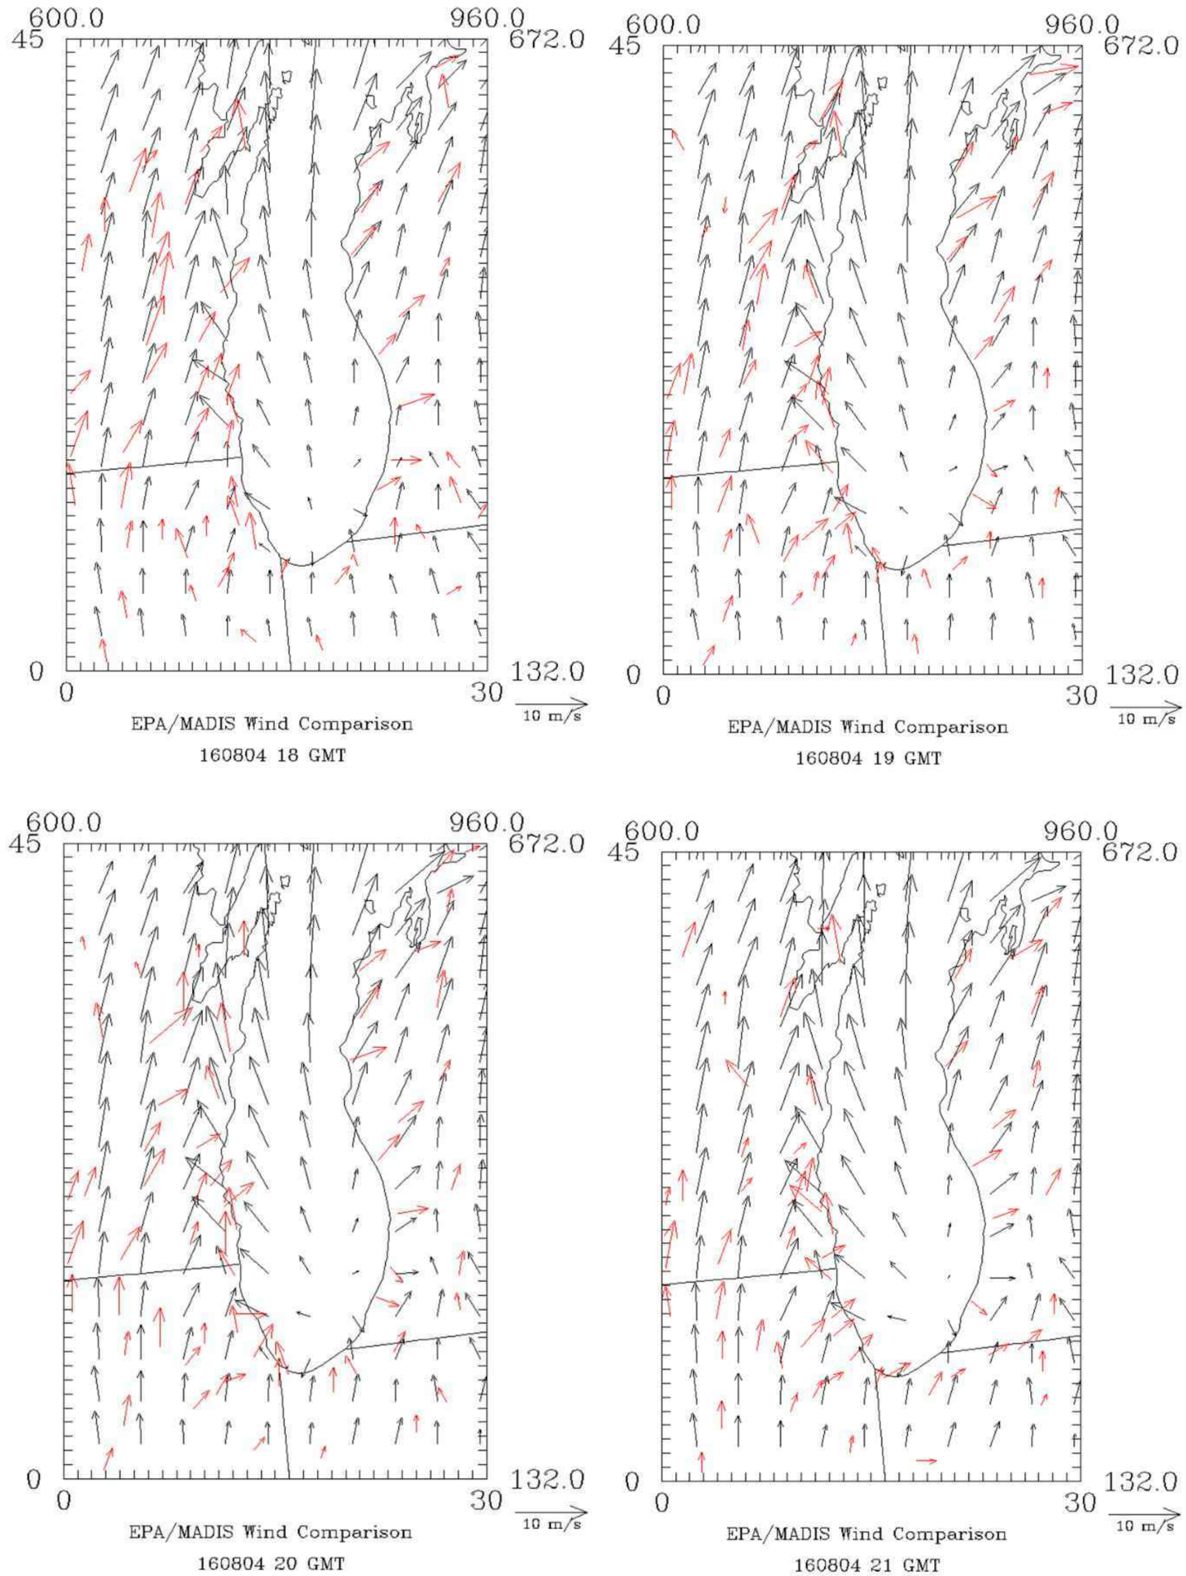

Figure 2. Model estimated (black) and observed (red) winds in the Lake Michigan area at 1300 CDT (top left), 1400 CDT (top right), 1500 CDT (bottom left), and 1600 CDT (bottom right) on August 4, 2016.

These large differences in observed and modeled wind directions are altering the concentration calculations as well as the source/receptor relationships (e.g., determining which sources are "upwind") of the Illinois monitors. As a result, the model cannot accurately reproduce the chemical processes involved with ozone formation. The erroneous modeled meteorological conditions fundamentally change the ozone formation chemistry and modeled source contributions as the chemical transport model predicts more emissions coming from the Chicago urban area than likely the case consistent with the observed wind fields.

When the model is having difficulty resolving fundamental flow patterns in this region with this grid size resolution, EPA needs to reconsider the merit of using the model with this configuration to determine nonattainment status in Step 1 as well as linked significant contributors at receptors in this region under Step 2. For these reasons, EPA must consider finer grid resolution modeling over the Lake Michigan domain to adequately capture ozone formation and significant contribution at receptors located on complex land-water interfaces because model evaluation shows that the model fails to adequately characterize ozone production at these monitors.

Absent a wholesale revision of EPA's modeling protocol, it is our opinion that EPA's use of modeling with poor performance at critical monitors amounts to an unreliable result when used to establish nonattainment or maintenance monitors under Step 1 or linkages under Step 2 of the 4-step framework. Should more refined modeling be undertaken to review the ozone formation potential at monitors located in these land-water interfaces, results may show that these monitors demonstrate modeled attainment and/or remove significant contribution linkages from upwind states.

3. EPA is obligated to address VOC emissions as a critical factor that is influencing ozone nonattainment/maintenance monitors in Illinois

EPA's modeling fails to account for VOC-limited conditions in the Lake Michigan region. Recent information supports the conclusion that VOC-limited conditions in the regional are much more significant that EPA has assumed. This results in EPA's analysis overemphasizing upwind NOx contributions from Minnesota on ozone values at the Alsip/Village Garage monitor and an underemphasis on local VOC contributions, which can be more effectively used to control ozone.

In addition to grid size resolution and complex meteorology issues, modeling performed by EPA[16] and the LMOS 2017 study both showed a negative bias in predicted ozone concentrations in the Lake Michigan region. LMOS 2017 study researchers have experimented with increasing

[16] EPA-HQ-OAR-2021-0668-0099

anthropogenic VOC emissions and decreasing anthropogenic NOx emissions. These emission changes improved air quality model performance reducing the negative bias. VOC speciation and spatio-temporal release patterns should also be reviewed. This evaluation by the LMOS 2017 research scientists indicates there are significant errors in the quantity and speciation of the VOC/NOx emissions used in the EPA's air quality modeling platform to characterize state contribution to ozone in Step 2 of EPA's analyses linking these states to critical nonattainment monitors.

Several downwind nonattainment monitors in urban areas around Lake Michigan recently have been shown to be largely unresponsive to ozone reduction strategies consisting of regional interstate NOx control and that high ozone days in the region were predominantly VOC-limited in nature. This was demonstrated in multiple ozone episodes extensively evaluated in the Lake Michigan Air Directors Consortium (LADCO) Lake Michigan Ozone Study (LMOS) 2017 study[17] where ozone precursor measurements indicated relative increases in VOC concentrations with increases in ozone and where biogenic VOC increases outpaced those of anthropogenic VOC.

In contrast to the peer reviewed research resulting from the 2017 LMOS data collection effort, EPA recently documented its support for additional NOx controls in stating that its "review of the portion of the ozone contribution attributable to anthropogenic NOX emissions versus VOC emissions from each linked upwind state leads the Agency to conclude that the vast majority of the downwind air quality areas addressed by the proposed rule under are primarily NOX-limited, rather than VOC-limited."[18] However, the current situation is that the modeling as conducted does not accurately characterize ozone levels on high ozone days, underpredicting by 10 + ppb, which is a huge error. Other studies indicate that, to better match actual conditions, the model needs less NOx and higher windspeeds at lower levels. The model is therefore demonstrating that less NOx means more ozone and higher ozone concentrations. That further means that, proportionally, the attribution of ozone to out of state NOx predicts a higher impact than is occurring.

The modeled VOC and NOx emission tracers in EPA's Anthropogenic Precursor Culpability Assessment (APCA) modeling can give a general indication of the VOC/NOx sensitivity, but EPA assigning definitive numerical values to that sensitivity provides inaccurate projections, especially using APCA that is known to have a bias toward attributing ozone to NOx emitting anthropogenic sources under VOC sensitive conditions. As documented in the CAMx v 7.10 User's Guide[19], "when ozone formation is due to biogenic VOC and anthropogenic NOx under

[17] https://www.ladco.org/wpcontent/uploads/Research/LMOS2017/LMOS_LADCO_report_revision_apr2019_final.pdf
[18] 87 Fed. Reg. 20,076
[19] https://camx-wp.azurewebsites.net/Files/CAMxUsersGuide_v7.10.pdf, page 177.

VOC-limited conditions (a situation where OSAT would attribute ozone production to biogenic VOC), APCA attributes ozone production to the anthropogenic NOx present. Using APCA instead of OSAT results in more ozone formation attributed to anthropogenic NOx sources and less ozone formation attributed to biogenic VOC sources." Here, it is believed that as applied in this case (with biogenic emissions as an uncontrollable source group), EPA has overestimated the efficacy of NOx controls on these receptors as modeled results have a bias toward attributing more ozone formed to NOx emissions than VOC emissions.

Furthermore, an independent review of EPA's own NOx and VOC contributions challenges the Agency's statement that "[o]ur analysis of the ozone contribution from upwind states subject to regulation under this proposed rule demonstrates that the vast majority of the downwind air quality areas are NOX-limited, rather than VOC-limited."[20] This statement is based on all anthropogenic NOx and VOC emissions from all upwind states and is defined as having NOx emissions contribute to 80% or more of the ozone concentrations modeled at each receptor[21].

EPA further goes on to state that "[t]his review of the portion of the ozone contribution attributable to anthropogenic NOX emissions versus VOC emissions from each linked upwind state leads the Agency to conclude that the vast majority of the downwind air quality areas addressed by the proposed rule under are primarily NOX-limited, rather than VOC-limited."[22]

Alpine's review of EPA's modeled NOx and VOC contributions, by upwind state, focusing on the future year modeled days used in each receptor's Step 2 linkage calculation provides a slightly different picture for monitors around Lake Michigan. As demonstrated in Table 5, of the top future year modeled days impacting significant contribution calculations at the Cook County, Illinois monitor with which Minnesota is linked, more than half of the days are shown to have NOx emission contributions from Illinois below the 80% threshold noted by EPA in determining NOx-limited regions. This is an indicator that on those days, and from anthropogenic sources from those states, VOC controls may demonstrate meaningful impact on ozone concentration reductions at this receptor.

Researchers at the University of Maryland (UMD) have also found in a study of chemical transport model results that by 2023, model predictions of ozone formed under VOC-limited conditions are substantial near the Long Island Sound and the Great Lakes. In a recent presentation[23], they document a source apportionment simulation, conducted with CAMx/APCA on future-year 2023 to determine the major contributing sources and states to air

[20] 87 Fed. Reg. 20053

quality within non-attainment areas. Their findings indicate that ozone production under VOC-limited conditions is important at coastal locations near Long Island Sound and the Great Lakes.

		2023 O3	O3N / O3N+O3V Contribution

Table 5. Modeled ozone contributions to Cook, Illinois monitor (170310001) by percent of emissions from anthropogenic NOx (O3N) compared to emissions from anthropogenic NOx and VOC (O3). Yellow cells indicate contributions of anthropogenic VOC emissions greater than EPA identified "NOx-limited" areas.

Figure 3 presents UMD's findings for model predictions of ozone formation under NOx limited conditions excluding the influence of boundary and initial conditions from the modeling input. As can be seen in these figures, regions around Lake Michigan demonstrate a significantly higher percentage of ozone formed by VOC (blue in color) compared to NOx than most of the eastern US. This observation is seen both on modeled days greater than 60 ppb and on the top ten days of the ozone season (days used in RRF and significant contribution calculations).

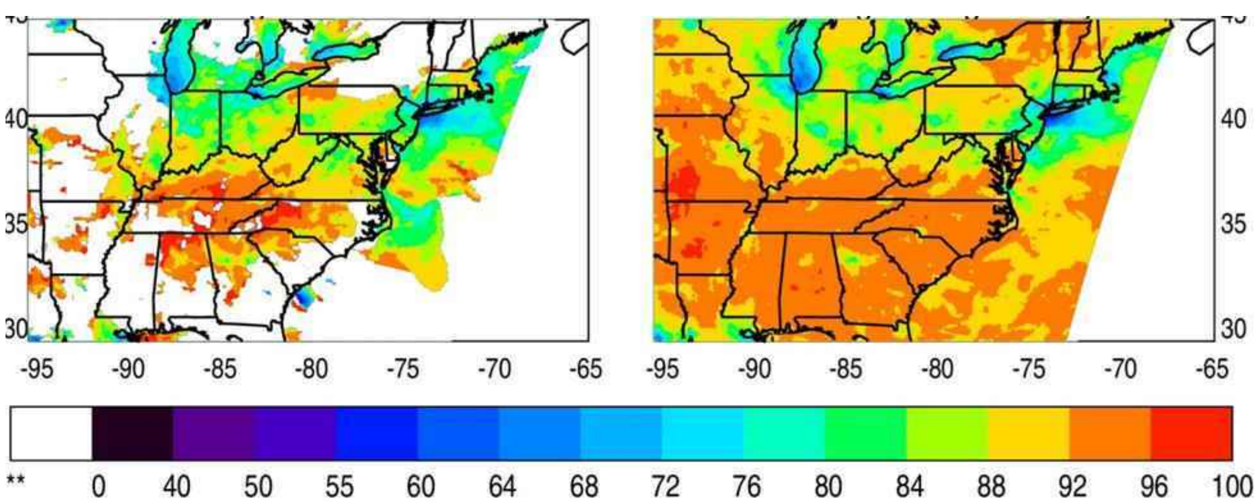

Figure 3. Percent of ozone formed under NOx-limited conditions excluding boundary and initial conditions on all days of MDA8 ozone > 60 ppb (left) and on top ten modeled days (right).

It is also noted that these estimates are a very conservatively high estimate of NOx limited conditions for these coastal areas. In addition to the previous comments highlighting that APCA is known to have a bias toward attributing ozone to NOx emitting anthropogenic sources under VOC sensitive conditions, the UMD analysis footnotes that the APCA run used to generate the results presented in Figure 3 suggests that model configuration led to an underestimation of the contribution of anthropogenic sources to ozone formation, especially during periods of VOC limited chemistry, and as is seen in Figure 3, in the Cook County, Illinois area.

As a result of these findings, EPA is obligated to address the concern that VOC emissions are a factor that is influencing ozone nonattainment and maintenance monitors in Illinois and elsewhere and that EPA determination of ozone nonattainment or maintenance in these areas may be inappropriate for significant contribution and upwind state linkage calculation. It is also our opinion that after review of VOC contribution and limited ozone reduction potential in Chicago and other noted areas, EPA may find that emission reduction plans may fail to justify regional NOx rules for monitors within these transitional and VOC-limited domains.

B. U.S. EPA's revisions to its modeling approach since MPCA's SIP submittal were ancillary.

EPA failed to give appropriate recognition of the merit of the MPCA SIP submitted on October 1, 2018, meeting the statutory deadline for submittal of interstate transport SIPs for the 2015 ozone NAAQS. The submission utilized both EPA modeling released with the March 2018 memorandum and LADCO modeling results previously mentioned. Minnesota followed the 4-step interstate transport framework and used an analytic year of 2023 to describe Minnesota's lack of contributions to out of state receptors and assess emission reduction considerations.

Under the CAA, on April 1, 2019, MPCA's SIP was deemed to be complete since EPA did not act within the 6 months from the date the SIP was submitted. April 1, 2020, 12 months after the completeness date, was the deadline for EPA to have acted on the MPCA SIP submission. Upon this deadline a full, partial or conditional approval was required by CAA Section 110(k)(2), (3), or (4).[24] In this regard, EPA failed to complete its non-discretionary duty to have reviewed and acted upon the MN SIP by April 1, 2020.

It wasn't until February 22, 2022, three years and four months after submittal, that EPA finally assessed the Minnesota SIP submittal and proposed disapproval of the SIP[25] as follows: "Based on EPA's evaluation of Minnesota's SIP submission and after consideration of updated EPA modeling using the 2016-based emissions modeling platform, EPA is proposing to find that the portion of Minnesota's October 1, 2018 SIP submission addressing CAA section 110(a)(2)(D)(i)(I) does not meet the state's interstate transport obligations for 2015 ozone NAAQS, because it fails to contain the necessary provisions to eliminate emissions that will contribute significantly to nonattainment or interfere with maintenance of the NAAQS in any other state."

The EPA reiterated this assessment and issued a partial approval on February 13, 2023, in their final rule stating that "Although the EPA acknowledges that Minnesota's Step 3 analysis was insufficient in part because the State assumed it was not linked at Step 2, this is ultimately inadequate to support a conclusion that the State's sources do not interfere with maintenance of the 2015 ozone NAAQS in other states in light of more recent air quality analysis."[26]

---

[24] **Deadline for Action**. – Pursuant to the CAA Section 110(k)(1)(B) "Within 12 months of a determination by the Administrator (or a determination deemed by operation of law) under paragraph (1) that a State has submitted a plan or plan revision (or, in the Administrator's discretion, part thereof) that meets the minimum criteria established pursuant to paragraph (1), if applicable (or, if those criteria are not applicable, within 12 months of submission of the plan or revision), the Administrator shall act on the submission in accordance with paragraph (3)."

[25] 87 Fed. Reg. 9838

[26] 88 Fed. Reg. 9357

1. EPA's Failure to Act

MPCA has been disadvantaged by EPA's delay in acting to approve or disapprove its 2015 Good Neighbor SIP, which was submitted to EPA on October 1, 2018. EPA published its proposed disapproval on February 22, 2022, and relied in part on newer, updated modeling performed by the EPA which was not available when MPCA submitted its revised SIP. On February 13, 2023, EPA published its final disapproval and again relied on even newer, updated modeling only released with the rule.

By delaying its final decision on Minnesota's submittal for nearly four and a half years, EPA moved the goal post for Minnesota—an act the DC Circuit rebuked in New York v. EPA, 964 F.3d 1214, 1223 (D.C. Cir. 2020). If EPA were to review and approve or disapprove SIPs within the timeframes required by the CAA, EPA would have conducted its review based on the same modeling and data that was available at the time the SIP was submitted and that has been documented in the sections above. EPA offers no indication that additional material information was available to EPA on April 1, 2020, when agency action on the Minnesota SIP was required that could justify disapproval of the Minnesota SIP.

Further, the updated modeling that EPA now offers to support a SIP review has not been adequately available to be reviewed, analyzed, and commented on in advance of any final decision on the subject SIP disapproval.

2. EPA has not developed any official guidance for states to follow in submitting a Good Neighbor SIP

The Good Neighbor SIP has been a required SIP element since the implementation of the 1997 8- hour ozone standard. In the intervening years, EPA has issued no official guidance for states to use in developing an approvable Good Neighbor SIP. It is unclear what standard or criteria EPA uses to determine approvability.

In its only direction on the subject, EPA released three 2018 memos that included modeling and discussion on potential flexibilities in approaches that could be used by states in developing their Good Neighbor SIPs. However, EPA has now disapproved MPCA's SIP which was based on EPA's own modeling results from the memo because it "does not meet the state's interstate transport obligations for 2015 ozone NAAQS, because it fails to contain the necessary provisions to eliminate emissions that will contribute significantly to nonattainment or interfere with maintenance of the NAAQS in any other state."[27]

[27] 87 FR 9869

From the memos, the only concrete guidance states have been provided is the four-step framework. Applied appropriately in the MPCA SIP, this framework demonstrated that Minnesota was not significantly linked to any downwind nonattainment or maintenance monitor. Since MPCA used EPA's own modeling and four-step approach to prepare its SIP, the SIP was approvable at the time submitted and was approvable when EPA was required to act on the SIP on April 1, 2020.

3. EPA's ever-changing list of nonattainment and maintenance monitors moves the target for Minnesota without offering any basis to reject MPCA's original analysis.

As detailed earlier, MPCA's air quality projections based on the ozone modeling conducted by LADCO in October 2018 was corroborated by EPA's own contribution modeling released with the March 2018 flexibilities memorandum and that showed that Minnesota was not linked to any monitor designated as nonattainment or maintenance for the 2015 ozone NAAQS in 2023. In those two modeling studies, the Cook County, Illinois monitor now linked to Minnesota was calculated to be in attainment for the 2015 ozone NAAQS.

Table 6 provides the average and maximum projected design values from the LADCO modeling that supported the original MPCA iSIP and March 2018 EPA memo modeling for this monitor demonstrating modeled attainment at this location.

			LADCO Modeling		EPA March 2018 Memo	
AQS Site ID	State	County	2023 Average DV	2023 Maximum DV	2023 Average DV	2023 Maximum DV
170310001	Illinois	Cook	62.8	64.6	63.2	64.9

Table 6. LADCO and EPA 2023 ozone design values (ppb) for Minnesota linked Cook County, Illinois monitor from original MPCA SIP and March 2018 EPA memo modeling results.

EPA's proposed disapproval mentions new modeling conducted by EPA in the interim where this Illinois monitor is ultimately identified as a maintenance monitor. Table 7 below provides the average and maximum projected design values from these studies and from the final SIP disapproval for this monitor.

In the proposed SIP disapproval, EPA cites the "results of a prior round of 2023 modeling using the 2016v1 emissions platform which became available to the public in the fall of 2020 in the Revised CSAPR Update." [28] In this Revised CSAPR Update modeling, developed for use with the 2008 ozone NAAQS analyses, monitor 170310001 is identified as a maintenance monitor in

[28] Footnote 94, 87 FR 9869

EPA's results. In EPA's results published in the proposed SIP disapproval[29] and in the final SIP disapproval[30], EPA continued to identify this monitor as a maintenance monitor.

	EPA Revised CSAPR Update		EPA Proposed SIP Disapproval		EPA Final SIP Disapproval	
AQS Site ID	2023 Ave DV	2023 Max DV	2023 Ave DV	2023 Max DV	2023 Ave DV	2023 Max DV
170310001	68.4	72.2	69.6	73.4	68.2	71.9

Table 7. EPA 2023 ozone design values (ppb) for Cook County, Illinois monitor from EPA cited modeling results in proposed and final Minnesota SIP disapproval.

In our opinion, EPA should always rely on the best available modeling at the time that an analysis is conducted and results, whether in a SIP or other, are developed and submitted. In this case, EPA has failed to follow this process and instead continued to move the target and objectives for states that, in Minnesota's case, for over four years and four months had been waiting for a review of their "best available data and analysis".

4. Alternative 1 ppb significance threshold

Neither the LADCO modeling nor EPA modeling released with the March 2018 memorandum indicated that Minnesota would contribute over 1% of the NAAQS to any nonattainment or maintenance monitor in 2023. As a result, Minnesota did not think it necessary to consider using a 1 ppb threshold for significant contribution to downwind receptors, which EPA guidance offered as an option to States.

In the SIP disapproval, EPA further elaborates that following their receipt and review of forty-nine good neighbor SIPs for the 2015 ozone NAAQS, their experience was that no state relying on a 1 ppb threshold provided sufficient information and technical support to justify that an alternative threshold was reasonable[31]. EPA does not indicate how many of the reviewed SIPs used a 1 ppb threshold nor do they indicate on how many state SIPs they provided feedback, if any. They go on to state that this alternate 1 ppb threshold may also be politically inconsistent and impractical under the CAA[32].

As EPA not only failed to provide any feedback to Minnesota on its original October 1, 2018 SIP submittal until the February 22, 2022 proposed SIP disapproval, EPA has also failed to honor its March 2018 guidance[33] which was identified to specifically "*provide analytical information*

[29] Table 5, 87 FR 9868
[30] Table III.B-2, 88 FR 9351
[31] 87 FR 9843
[32] Footnote 33, 87 FR 9843
[33] https://www.epa.gov/sites/default/files/2018-03/documents/transport_memo_03_27_18_1.pdf

regarding the degree to which certain air quality threshold amounts capture the collective amount of upwind contribution from upwind states to downwind receptors or the 2015 ozone NAAQS. It also interprets that information to make recommendation about what thresholds may be appropriate for use in state implementation plan (SIP) revisions addressing the good neighbor provision for that NAAQS."

Minnesota has been denied the opportunity to correct the model inputs that EPA uses as the basis for SIP Disapproval at the 1% threshold and denied the opportunity to update its SIP to take advantage of the 1 ppb threshold that EPA offers States an opportunity to justify in its guidance. While EPA continues to regenerate results based on updated emission modeling platforms and other associated information, states have been omitted from the process, denying them the chance to review updated information and to provide revisions to their SIPs to address those updates.

It is important to note that under all of EPA's cited modeling results, Minnesota contributes under the 1 ppb permitted to be considered from EPA's March 2018 guidance. Table 8 below shows that under none of EPA's four modeling platforms does Minnesota contribute over the 1 ppb threshold to the Cook County monitor.

			Minnesota Contribution (ppb) in 2023			
AQS Site ID	**State**	**County**	**EPA March 2018 Memo**	**EPA Revised CSAPR Update**	**EPA Proposed SIP Disapproval**	**EPA Final SIP Disapproval**
170310001	Illinois	Cook	0.76	0.79	0.97	0.85

Table 8. Minnesota contribution to Cook County, Illinois 2023 ozone design values from documented modeling platforms.

EPA's 2018 flexibility memos, including the opportunity for states to make recommendations to support alternate thresholds for significant contribution, remains an important tool for addressing unique State circumstances in developing their good neighbor SIPs. Disapproving the Minnesota SIP without affording the State an opportunity to utilize this flexibility is unreasonable and should be reconsidered.

C. The Minnesota Pollution Control Agency's state implementation plan revision was approvable based on the state of the science at the time it was submitted to U.S. EPA.

1. Introduction

On October 1, 2018, the Minnesota Pollution Control Agency, after review and comment by EPA Region 5 staff, submitted to the U.S. Environmental Protection Agency a request for revision of Minnesota's State Implementation Plan[34].

The proposed SIP revision addressed Minnesota's responsibilities relating to the "Infrastructure" SIP (iSIP) requirements of sections 110(a)(l) and 110(a)(2) of the Clean Air Act (CAA), as they pertain to the National Ambient Air Quality Standard (NAAQS) for ozone, promulgated in 2015. The CAA requires states to submit an iSIP within three years of the EPA's issuance of a new NAAQS to demonstrate their continued ability to implement, maintain, and enforce the federal standards. The iSIP outlined the statutes, rules, and programs that enable Minnesota to ensure attainment of the 2015 ozone NAAQS. These statutes, rules, and programs had previously been reviewed and approved into Minnesota's iSIP, and the materials included with the iSIP demonstrate that the MPCA did not have further obligations under the iSIP requirements.

The MPCA submission utilized both EPA modeling released with a March 2018 flexibilities memorandum[35] and Lake Michigan Air Directors Consortium (LADCO) modeling results[36]. Minnesota followed the 4-step interstate transport framework and used an analytic year of 2023 to describe Minnesota's lack of contributions to out of state receptors and assess emission reduction considerations.

In this document we discuss both the technical and legal validity of MPCA's SIP and EPA's obligation to approve the SIP.

EPA's and LADCO's model projections, along with continuing decreases in the emissions and monitored levels of ozone precursors in Minnesota (nitrogen dioxide and volatile organic compounds), demonstrated that no additional controls or emissions limits were necessary to

[34] EPA-R05-OAR-2018-0689-0003

[35] https://www.epa.gov/interstate-air-pollution-transport/memo-and-supplemental-information-regarding-interstate-transport

[36] https://www.ladco.org/wp-content/uploads/Documents/Reports/TSDs/O3/LADCO_2015O3iSIP_TSD_13Aug2018.pdf

fulfill Minnesota's responsibilities under the good neighbor provisions for the 2015 ozone NAAQS.

On February 13, 2023, almost four and a half years after the original SIP submittal, EPA finalized a rule in connection with the Air Plan Disapprovals; Interstate Transport Requirements for the 2015 8-Hour Ozone National Ambient Air Quality Standards[37].

EPA notes in this final rule, that these disapprovals would not start a mandatory sanctions clock but rather would establish a 2-year deadline for EPA to promulgate a Federal Implementation Plan (FIP), unless EPA were to approve a subsequent SIP submittal that meets CAA requirements. EPA originally proposed a FIP to be finalized December 15, 2022, in complete disregard for the 2-year period allowed by the CAA for responding to any such SIP disapprovals[38]. This FIP[39] was signed by the Administrator on March 15, 2023, and is still awaiting publication in the Federal Register.

In 2018 EPA issued flexibility guidance for states to follow in development of 2015 ozone standard NAAQS God Neighbor SIPs (GNS). We specifically question how EPA's late disapproval contradicts this guidance.

2. MPCA's Modeling Approach

The modeling performed to support the SIP was performed by LADCO and except for the 2023 projected EGU emissions, was identical to the "EN" platform developed by EPA and followed EPA guidance[40] in preparation of technical material for SIP and SIP-related modeling. The EN platform was used by EPA in its March 2018 flexibility memorandum so that "[s]tates can use these data to develop their implementation plans to assure that emissions within their jurisdictions do not contribute significantly to nonattainment or interfere with maintenance of the 2015 ozone standards in other states."

In our opinion, this platform was technically credible, and a SIP developed from these data should have been approvable by EPA at the time of submission in October 2018. The following sections present our opinions on specific technical aspects of MPCA modeling.

[37] Id.
[38] 87 Fed. Reg 20036
[39] https://www.epa.gov/system/files/documents/2023-03/FRL%208670-02-OAR_Good%20Neighbor_Final_20230314_Signature_ADMIN%20%281%29.pdf
[40] https://www.epa.gov/sites/production/files/2020-10/documents/o3-pm-rh-modeling_guidance-2018.pdf

Base Year

The base year for the MPCA modeling was 2011. 2011 was selected because of data availability and because EPA[41] had noted that 2011 meteorology in the Eastern U.S., including the upper Midwest, was warmer and drier that the climatic norm and represented typical conditions conducive to high observed ozone concentrations in the Midwest and Northeast U.S. It is Alpine's opinion that 2011 was an appropriate modeling year.

Model and Data Selection

This section introduces the models and data sources used in the MPCA. The selection methodology followed EPA's guidance for ozone regulatory modeling[42],[43],[44]. EPA's 2018 modeling guidance[45] lists several criteria for model selection that are paraphrased as follows (pp. 24-27):

- It should not be proprietary;
- It should have received a scientific peer review;
- It should be demonstrated to be applicable to the problem on a theoretical basis;
- It should be used with data bases which are available and adequate to support its application;
- It should be shown to have performed well in past modeling applications;
- It should be applied consistently with an established protocol on methods and procedures;
- It should have a user's guide and technical description;
- The availability of advanced features (e.g., probing tools or science algorithms) is desirable; and

- When other criteria are satisfied, resource considerations may be important and are a legitimate concern.

It is Alpine's opinion that the models chosen for the MPCA modeling met these criteria and were appropriate for use in the SIP.

Meteorological Modeling

The Weather Research and Forecasting (WRF) Model is a mesoscale numerical weather prediction system designed to serve both operational forecasting and atmospheric research needs[46],[47],[48]. The Advanced Research WRF (ARW) version of WRF was used in the MPCA modeling study. It features multiple dynamical cores, a 3-dimensional variational (3DVAR) data assimilation system, and a software architecture allowing for computational parallelism and system extensibility. WRF is suitable for a broad spectrum of applications across scales ranging from meters to thousands of kilometers. The effort to develop WRF has been a collaborative partnership, principally among the National Center for Atmospheric Research (NCAR), the National Oceanic and Atmospheric Administration (NOAA), the National Centers for Environmental Prediction (NCEP) and the Forecast Systems Laboratory (FSL), the Air Force Weather Agency (AFWA), the Naval Research Laboratory, the University of Oklahoma, and the Federal Aviation Administration (FAA). WRF allows researchers the ability to conduct simulations reflecting either real data or idealized configurations. WRF provides operational forecasting a model that is flexible and efficient computationally, while offering the advances in physics, numerics, and data assimilation contributed by the research community.

WRF is publicly available, has full documentation and has demonstrated success in simulating meteorological conditions in the Upper Midwest.

MPCA used the U.S. EPA 2011 WRF data for this study[49]. The U.S. EPA used version 3.4 of the WRF model, initialized with the 12-km North American Model (NAM) from the National Climatic Data Center (NCDC) to simulate 2011 meteorology. Complete details of the WRF simulation, including the input data, physics options, and four-dimensional data assimilation (FDDA) configuration are detailed in the U.S. EPA 2008 Transport Modeling technical support document[50]. U.S. EPA prepared the WRF data for input to CAMx with version 4.3 of the WRFCAMx software.

It is Alpine's opinion that the U.S. EPA WRF 3.4 meteorological modeling was appropriate for use in the MPCA SIP.

Initial and Boundary Conditions

MPCA used 2011 initial and boundary conditions for CAMx generated by the U.S. EPA from the GEOS-Chem Global Chemical Transport Model[51]. EPA generated hourly, one-way nested boundary conditions (i.e., global-scale to regional-scale) from a 2011 2.0 degree x 2.5 degree GEOS-Chem simulation. Following the convention of the U.S. EPA O3 transport modeling, year 2011 GEOS-Chem boundary conditions were used by LADCO for modeling 2023 air quality with CAMx.

It is Alpine's opinion that the U.S. EPA GEOS-Chem derived initial and boundary conditions were appropriate for use in the MPCA SIP.

Emissions

The 2023 emissions data for the MPCA SIP were based on the U.S. EPA 2011v6.3 ("EN") emissions modeling platform[52]. U.S. EPA generated this platform for their final assessment of Interstate Transport for the 2008 O3 NAAQS. Updates from earlier 2011-based emissions modeling platforms included a new engineering approach for forecasting emissions from Electricity Generating Units (EGUs). LADCO replaced the EGU emissions in the U.S. EPA EN

platform with 2023 EGU forecasts estimated with the ERTAC EGU Tool version 2.7[53]. ERTAC EGU 2.7 integrates state-reported information on EGU operations and forecasts as of May 2017. The MPCA believes "power sector emissions forecasts must address economic factors, preserve system reliability, and include controls or emission reduction measures justified through some legal framework. It is our understanding that the engineering analysis used by EPA to project EGU emissions to 2023 (version EN of the modeling platform) does not comply with these key requirements. The ERTAC estimates incorporate the key requirements."[54]

In March 2018 U.S. EPA released it flexibilities memo that described a series of flexibilities that states could consider in developing Good Neighbor SIPs for the 2015 ozone NAAQS. The "[u]se of alternative power sector modeling consistent with EPA's emissions inventory guidance" is presented in the Analytics section of EPA's March 2018 memo as a flexibility to consider in preparing a Good Neighbor SIP. This flexibility supports LADCO's use of the ERTAC EGU model for projecting EGU emissions to 2023. MPCA considers the emissions projections from ERTAC EGU to be more representative of the sources in the Midwest and Northeast than the approach used by U.S. EPA in their 2023 EN modeling platform. As ERTAC EGU is developed in collaboration between regional and state air planning agencies, it includes algorithms and data that have been reviewed by many of the states impacted by interstate O3 transport in the Midwest and Eastern U.S.

Preparation of the emissions data to support photochemical models is a very complicated process that entails the use of a number of different "sub-models" to prepare different emission segments.

Sparse Matrix Operator Kernel Emissions (SMOKE)

The Sparse Matrix Operator Kernel Emissions (SMOKE) is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, non-road, area, point, fire and biogenic emission sources for PGMs[55],[56]. As with most "emissions models," SMOKE is principally an emission processing system and not a true emissions modeling system in which emissions estimates are simulated from "first principles." This means that, except for mobile and biogenic sources, its purpose is to provide an efficient, modern tool for converting an existing base emissions inventory data that is typically at the county or point source level into

---

[54] EPA-R05-OAR-2018-0689-0003

[55] Coats, C.J. 1995. Sparse Matrix Operator Kernel Emissions (SMOKE) Modeling System, MCNC Environmental Programs, Research Triangle Park, NC.

[56] UNC. 2018. SMOKE v4.6 User's Manuel. University of North Carolina at Chapel Hill, Institute for the Environment. Chapel Hill, North Carolina. September 24. (https://www.cmascenter.org/smoke/documentation/4.6/manual_smokev46.pdf).

the hourly gridded speciated formatted emission files required by a Photochemical Grid Model (PGM), like CAMx. SMOKE was used to prepare emission inputs for non-road mobile, non-point (area) and point sources. SMOKE performs three main function to convert emissions to the hourly gridded emission inputs for a PGM: (1) spatial allocation, spatial allocates county-level emissions to the PGM model grid cells typically using a surrogate distribution (e.g., population); (2) temporal allocation, allocates annual emissions to time of year (e.g., monthly or seasonally) and day-of-week (typically weekday, Saturday and Sunday); and (3) chemical speciation, maps the emissions to the species in the chemical mechanism used by the photochemical grid model, most important for VOC and $PM_{2.5}$ emissions.

The primary emissions modeling tool used to create the air quality model-ready emissions was the SMOKE modeling system version 3.7 which was used to create emissions files for a 12-km national grid "12US2" that includes all of the contiguous states.

It is Alpine's opinion that the SMOKE emissions model together with the other EPA emissions was appropriate for use in the MPCA SIP.

Motor Vehicle Emissions Simulator (MOVES)

The motor vehicle emissions were prepared by U.S. EPA using the MOVES 2014a emissions model[57],[58],[59]. MOVES 2014a was the most up to date released motor vehicle emissions processor at the time of the MPCA SIP submission and it is Alpine's opinion that the U.S. EPA MOVES 2014a emissions were appropriate for use in the MPCA SIP.

Eastern Regional Technical Advisory Committee EGU Model

The Eastern Regional Technical Advisory Committee (ERTAC) EGU model for growth was developed around activity pattern matching algorithms designed to provide hourly EGU emissions data for air quality planning. The original goal of the model was to create low-cost software that air quality planning agencies could use for developing EGU emissions projections. States needed a transparent model that was numerically stable and did not produce dramatic changes to the emissions forecasts with small changes in inputs. A key feature of the model

---

[57] EPA. 2014a. Motor Vehicle Emissions Simulator (MOVES) – User Guide for MOVES2014. Assessment and Standards Division, Office of Transportation and Air Quality, U.S. Environmental Protection Agency. (EPA-420-B-14-055). July. (http://www.epa.gov/oms/models/moves/documents/420b14055.pdf).

[59] EPA. 2014b. Motor Vehicle Emissions Simulator (MOVES) –MOVES2014 User Interface Manual. Assessment and Standards Division, Office of Transportation and Air Quality, U.S. Environmental Protection Agency. (EPA-420-B-14-067). July. (http://www.epa.gov/oms/models/moves/documents/420b14057.pdf).

includes data transparency; all of the inputs to the model are publicly available. The code is also operationally transparent and includes extensive documentation, open-source code, and a diverse user community to support new users of the software.

Operation of the model is straightforward given the complexity of the projection calculations and inputs. The model imports base year Continuous Emissions Monitoring (CEM) data from U.S. EPA and sorts the data from the peak to the lowest generation hour. It applies hour specific growth rates that include peak and off-peak rates. The model then balances the system for all units and hours that exceed physical or regulatory limits. ERTAC EGU applies future year controls to the emissions estimates and tests for reserve capacity, generates quality assurance reports, and converts the outputs to SMOKE ready modeling files.

ERTAC EGU has distinct advantages over other growth methodologies because it can generate hourly future year estimates which are key to understanding ozone episodes. The model does not shutdown or mothball existing units because economics algorithms suggest they are not economically viable. Additionally, alternate control scenarios are easy to simulate with the model. Full documentation for the ERTAC Emissions model and 2.7 simulations are available through the MARAMA website[60].

Differences between the EPA and ERTAC EGU emissions forecasts arise from alternative forecast algorithms and from the data used to inform the model predictions. The U.S. EPA EGU forecast used in the 2023 EN modeling used CEM data available through the end of 2016 and comments from states and stakeholders received through April 17, 2017[61]. ERTAC EGU 2.7 used CEM data from 2011 and state-reported changes to EGUs through May 2017. The ERTAC EGU 2.7 emissions used for the modeling represented the best available information on EGU forecasts for the Midwest and Eastern U.S. available during Spring-early Summer 2018.

The “consideration of state-specific information in identifying sources [e.g., electric generating units (EGUs) and non-EGUs] and controls” is one of the potential approaches in EPA’s March 2018 flexibilities memorandum. The use of the ERTAC EGU tool falls squarely within the parameters of this documented flexibility and it is Alpine’s opinion that MPCA’s used of EGU emission projections from this model were appropriate in the MPCA SIP.

BEIS

Biogenic emissions were computed by U. S. EPA based on the same version of the 2011 meteorology data used for the air quality modeling and were developed using the Biogenic Emission Inventory System version 3.61 (BEIS3.61) within SMOKE. The landuse input into BEIS3.61 is the BELD version 4.1 which is based on an updated version of the USDA-USFS Forest Inventory and Analysis (FIA) vegetation speciation-based data from 2001 to 2014 from the FIA version 5.1.

It is Alpine's opinion that the U.S. EPA application of the BEIS model was appropriate for use in the MPCA SIP.

3. Air Quality Modeling

The MPCA modeling used the Comprehensive Air-quality Model with Extensions (CAMx) air quality model[62]. CAMx is a state-of-science "One-Atmosphere" multi-scale photochemical grid model (PGM) capable of addressing ozone, particulate matter (PM), visibility and acid deposition at regional, urban and local scale typically for periods of a year. CAMx is a publicly available open-source computer modeling system for the integrated assessment of gaseous and particulate air pollution. Built on today's understanding that air quality issues are complex, interrelated, and reach beyond the urban scale, CAMx is designed to (a) simulate air quality over many geographic scales, (b) treat a wide variety of inert and chemically active pollutants including ozone, inorganic and organic $PM_{2.5}$ and PM_{10} and mercury and toxics, (c) provide source-receptor, sensitivity, and process analyses and (d) be computationally efficient and easy to use.

The U.S. EPA has approved the use of CAMx for numerous ozone and PM State Implementation Plans throughout the U.S. and has used this model to evaluate regional mitigation strategies including those for most recent national transport rules, such as the Cross-State Air Pollution Rule (CSAPR), CSAPR Update, and the modeling used in justification of denial of the MPCA SIP. The MPCA used Version 6.4, which was released in December 2016. Unlike some of EPA's previous ozone modeling guidance that specified a particular ozone model (e.g., EPA 1991 Guidance[63]) or that specified the Urban Airshed Model (UAM)[64], the EPA now recommends that

---

[62] User's Guide: Comprehensive Air Quality Model with Extensions version 6.40. Novato, CA. http://www.camx.com/files/camxusersguide_v6-40.pdf

[63] Draft Guidance on the Use of Models and Other Analyses in Attainment Demonstrations for the 8-hr Ozone NAAQS". U.S. Environmental Protection Agency, Office of Air Quality Planning and Standards, Research Triangle Park, N.C. May.

[64] User's Guide for the Urban Airshed Model. Volume I: User's Manual for UAM (CB-IV) prepared for the U.S. Environmental Protection Agency (EPA-450/4-90-007a). Systems Applications International, San Rafael, CA.

models be selected for ozone SIP studies on a "case-by-case" basis. The latest EPA ozone guidance[65] (pp. 24) explicitly mentions the CAMx PGMs as one of the most commonly used PGMs that would satisfy EPA's selection criteria but notes that this is not an exhaustive list and does not imply that it is "preferred" over other PGMs that could also be considered and used with appropriate justification.

The CAMx model is updated regularly to both update the science in the model and to address coding errors (bugs) in the code. CAMx 6.5 was released at the end of April 2018, approximately 6 months prior to submission the MPCA SIP submission. It is customary for regulatory modeling to "freeze" the model version during the modeling process to keep the modeling on schedule.

It is Alpine's opinion that the CAMx 6.4 air quality model along with the EPA EN platform with 2023 EGU's updated to include ERTAC was appropriate for use in the MPCA SIP.

4. Model Performance

MPCA relied on the model performance evaluation (MPE) conducted by the U.S. EPA on the modeling platform that we used for this study[66] to establish validity in the modeling platform. In addition to the MPE for the base year CAMx simulation, the U.S. EPA reported full MPE results for the 2011 WRF modeling[67] used in the CAMx simulations.

It is Alpine's opinion that the EPA WRF and CAMx performance evaluations showed adequate performance and that the modeling was appropriate for use in the MPCA SIP.

5. Source Apportionment

MPCA used the CAMx Anthropogenic Precursor Culpability Assessment (APCA) tool to calculate emissions tracers for identifying upwind sources of ozone at downwind monitoring sites. MPCA

[65] Modeling Guidance for Demonstrating Air Quality Goals for Ozone, PM2.5, an Regional Haze. [67] US EPA. 2014. Meteorological Model Performance for Annual 2011 WRFv3.4 Simulation. Research Triangle Park, NC. https://www3.epa.gov/ttn/scram/reports/MET_TSD_2011_final_11-26-14.pdf.

used the APCA technique because it more appropriately associates ozone formation to anthropogenic sources than the CAMx Ozone Source Apportionment Technique (OSAT). If any anthropogenic emissions are involved in a reaction that leads to ozone formation, even if the reaction occurs with biogenic VOC or NOx, APCA tags the ozone as anthropogenic in origin.

The APCA source apportionment tool has a robust theoretical basis and a long application history and it is our opinion that the APCA tool is appropriate for identifying upwind sources of ozone at downwind monitoring sites.

6. Interstate Transport Provisions – Section 110(a)(2)(D)

This section of the CAA requires SIPs to have provisions prohibiting sources from emitting air pollutants in amounts that would contribute significantly to nonattainment or interfere with maintenance in any other state. These interstate transport requirements are often referred to as "good neighbor SIPs". The analyses conducted both by LADCO and EPA to support the 2015 ozone good neighbor SIPs show Minnesota does not contribute significantly to air quality problems in any downwind nonattainment or maintenance area. Therefore, no additional controls or emissions limits were required to fulfill Minnesota's good neighbor obligations.

On March 27, 2018, the EPA published a memo, entitled "Information on the Interstate Transport State Implementation Plan Submissions for the 2015 Ozone National Ambient Air Quality Standards under Clean Air Act Section 110(a)(2)(D)(i)(I)". EPA's Memo included new transport modeling data for the year 2023 (the Moderate Attainment deadline for the 2015 ozone NAAQS). These data are provided to assist states in completing the "good neighbor" SIPs for the 2015 ozone NAAQS, and to thereby address interstate transport obligations.

EPA identifies a four-step framework in the Memo, intended to guide states on how to go about developing good neighbor SIPs:

1. Identify downwind air quality problems;
2. Identify upwind states that contribute enough to those downwind air quality problems to warrant further review and analysis;
3. Identify the emissions reductions necessary (if any), considering cost and air quality factors, to prevent an identified upwind state from contributing significantly to those downwind air quality problems; and
4. Adopt permanent and enforceable measures needed to achieve those emissions reductions.

In Step 1, EPA identifies monitoring sites that are projected to have problems attaining and/or maintaining the NAAQS in the 2023 analytic year. Where EPA's analysis shows that a site does

not fall under the definition of a nonattainment or maintenance receptor, that site is excluded from further analysis under EPA's 4-step interstate transport framework. For sites that are identified as a nonattainment or maintenance receptor in 2023, we proceed to the next step of our 4-step interstate transport framework by identifying the upwind state's contribution to those receptors.

In Step 2, EPA quantifies the contribution of each upwind state to each receptor in the 2023 analytic year. The contribution metric used in Step 2 is defined as the average impact from each state to each receptor on the days with the highest ozone concentrations at the receptor based on the 2023 modeling. If a state's contribution value does not equal or exceed the threshold of 1 percent of the NAAQS (i.e., 0.70 ppb for the 2015 ozone NAAQS), the upwind state is not ''linked'' to a downwind air quality problem, and EPA, therefore, concludes that the state does not significantly contribute to nonattainment or interfere with maintenance of the NAAQS in the downwind states.

Comparably, in MPCA's SIP submission, they include LADCO's modeling which additionally follows the same transport framework and is corroborated by EPA's modeling with the data released with the March 2018 memo.

Step 1 - 2023 Air Quality Projections

MPCA's reported air quality projections[68] submitted with their SIP were based on the ozone modeling conducted by LADCO. The result of this LADCO 2023 modeling, using methods utilized by EPA and shown in Table 9 below, forecasted that no downwind monitors in the Midwest or Northeast would be nonattainment for the 2015 O3 NAAQS.

Table 10. EPA 2023 ozone design values at nonattainment and maintenance monitors in the Midwest and Northeast.

[69] https://www.epa.gov/sites/default/files/2018-05/updated_2023_modeling_dvs_collective_contributions.xlsx

An additional six monitors in Connecticut (90010017 and 90099002), Maryland (240251001), Michigan (260050003 and 261630019), and New York (360810124) would be considered maintenance monitors in the projection.

In neither the LADCO nor EPA modeling cited in MPCA's SIP revision submission were the two Cook County, Illinois monitors (170314201 and 170310076) from EPA's SIP denial NPR, or the single monitor from EPA's final SIP disapproval action, identified as either nonattainment or maintenance monitors in the 2023 projections.

Step 2 - Significant Contribution to Downwind States

EPA has previously determined that a state contribution to downwind air quality problems below one percent of the applicable NAAQS is insignificant. This screening method was used in previous good neighbor SIP approvals, and other regulatory actions including (most notably) the Cross-State Air Pollution Rule (CSAPR), and the CSAPR update for the 2008 ozone NAAQS and 2012 NAAQS for particulate matter less than 2.5 micrometers in diameter (PM2.5). The one percent screening method was developed through several previous federal notice and comment rulemakings. One percent of the 2015 ozone NAAQS (70 ppb) is 0.70 ppb. Therefore, any state that contributes less than 0.70 ppb to a projected nonattainment or maintenance area in another state is not culpable for those air quality problems.

EPA and LADCO applied the Anthropogenic Precursor Culpability Analysis (APCA) technique in CAMx to identify upwind states culpable for downwind ozone air quality problems. The method accounts for anthropogenic nitrogen oxides (NO_x) and volatile organic carbon (VOC) emissions from all sources in each upwind state affecting projected 2023 ozone concentrations at each downwind air quality monitoring site designated a nonattainment or maintenance receptor. EPA and LADCO conducted the culpability analysis for the period May 1 through September 30, using the 2023 future emission estimates and 2011 meteorology.

Both LADCO and EPA analyses[70] conclude Minnesota is not culpable for ozone nonattainment, or interference with maintenance, in any downwind states. As shown in Table 11, prepared using data from MPCA's SIP[71], LADCO's analysis shows a maximum contribution of 0.45 ppb to the identified maintenance monitors, less than the 0.70 ppb identified as 1% of the NAAQS (70 ppb). EPA's analysis[72] (Table 12) indicates Minnesota contributes most to Milwaukee, Wisconsin monitor site 550790085. At a concentration of 0.40 ppb, this contribution is roughly equal to 0.57% of the 2015 ozone NAAQS.

Table 12. EPA 2023 O3 design values at nonattainment and maintenance monitors in the Midwest and Northeast and Minnesota's calculated contribution.

For the reasons set forth in this section, it is our opinion that the modeling conducted and cited by MPCA in the development of its 2015 ozone NAAQS transport SIP revision of October 2018 was technically adequate and appropriate for the purpose it was intended and followed all available EPA guidance on preparing technical modeling for SIP and SIP-related analyses.

Additionally, in our opinion, the MPCA SIP adequately demonstrates that Minnesota is not a significant contributor to any downwind monitor identified as in nonattainment or maintenance for the 2015 ozone NAAQS and is corroborated by EPA modeling which included state-of-science configuration and platform at the time the original SIP was submitted.

D. Summary of Conclusions

For the reasons set forth in this document, it is our opinion that the modeling conducted and cited by MPCA in the development of its 2015 ozone NAAQS transport SIP revision of October 1, 2018 was technically adequate and appropriate for the purpose it was intended and should have been approved by EPA at the time of submission. It is further our opinion that decisions made by EPA to compare MPCA's original submitted modeling to recently updated modeling, developed by EPA over four years and four months later than the original Oct 2018 submission, are inconsistent with EPA precedent.

It is our opinion that in the absence of inclusion of Minnesota's and other stakeholder's valid emission modeling platform revision submissions, as requested by EPA, and multiple reruns of the air quality in both the base year (2016) and projection year (2023) simulations, EPA cannot appropriately identify monitors as nonattainment or maintenance, and in turn, cannot calculate upwind state significant contribution metrics from these same data. Non-EGU emission controls and their associated NOx emission reductions as documented and submitted by MPCA, could be enough to change nonattainment designations and linked significance using an updated platform and needs to be considered before making any final decision on denial of MPCA's SIP.

It is our opinion that EPA's use of modeling with poor performance at critical monitors amounts to an unreliable result when used to establish nonattainment or maintenance monitors under Step 1 or linkages under Step 2 of the 4-step framework. Should more refined modeling be undertaken to review the ozone formation potential at monitors located in these land-water interfaces, results may show that these monitors demonstrate modeled attainment and/or remove significant contribution linkages from upwind states.

It is our opinion that the most recent modeling cited by EPA and used to justify the linkage of Minnesota to one downwind maintenance monitors in Cook County, Illinois has technical issues as it relates to that linked monitor which is located in a complex land-water interface and may require finer grid resolution modeling to adequately capture ozone formation and significant contribution, and that EPA must address the impact of VOC emissions in influencing ozone formation at monitors in Illinois.

It is our opinion that EPA has failed to follow the process by relying on the best available modeling at the time that an analysis is conducted, and results are developed and submitted. Instead, EPA continues to move the target and objectives for states that, in Minnesota's case, for over four years had been waiting for a review of their "best available data and analysis".

It is our opinion that EPA should not have used any updated modeling to support a SIP review while not providing the opportunity for that data to be reviewed, analyzed, and commented on in advance of any final decision on the subject SIP disapproval and that any modeling beyond what was conducted in the original SIP submittal was ancillary to the approval process. However, should EPA decide not to review MPCA's SIP revision on its merit, Alpine recommends that EPA withdraw the SIP disapproval in favor of correcting the technical errors that have been identified in its analysis and to propose an appropriate opportunity for Minnesota to address any deficiencies EPA may find in Good Neighbor Plans implementing the 2015 ozone NAAQS.

It is our opinion that EPA's 2018 flexibility memo has become so instrumental to states in developing their good neighbor SIPs, that EPA's decision to disallow the flexibilities that they themselves outlined in guidance, is unreasonable and should be reconsidered.

Additionally, in our opinion, the MPCA SIP adequately demonstrates that Minnesota is not a significant contributor to any downwind monitor identified as in nonattainment or maintenance for the 2015 ozone NAAQS and is corroborated by EPA modeling which included state-of-science configuration and platform at the time the original SIP was submitted. It is our opinion that the original MPCA SIP was and is approvable.

E. Minnesota 2015 Ozone SIP Timeline

October 1, 2015 – EPA finalized the revised 2015 ozone NAAQS. Pursuant to CAA section 110(a)(1), "each state shall . . . submit to the Administrator, within 3 years. . .after promulgation of a [primary NAAQS] (or any revision thereof) a plan which provides for implementation, maintenance, and enforcement of such primary standard. . ." CAA section 110(a)(2)(D)(i)(I) requires such SIPs to "contain adequate provisions prohibiting . . .any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will contribute significantly to nonattainment in, or interfere with maintenance by, and other State with respect to such NAAQS.

March 27, 2018 - EPA published a memo, entitled "Information on the Interstate Transport State Implementation Plan Submissions for the 2015 Ozone National Ambient Air Quality Standards under Clean Air Act Section 110(a)(2)(D)(i)(I)". EPA's Memo included new transport modeling data for the year 2023 (the Moderate Attainment deadline for the 2015 ozone NAAQS). These data are provided to assist states in completing the "good neighbor" SIPs for the 2015 ozone NAAQS, and to thereby address interstate transport obligations.

October 1, 2018 - Minnesota Pollution Control Agency (MPCA) submitted a SIP revision to address CAA Section 110(a)(2)(D)(i)(I) on October 1, 2018 .[73] The submission met the statutory deadline for submittal the interest transport SIPs for the 2015 ozone NAAQS. The submission utilized both EPA modeling released with the March 2018 memorandum and LADCO modeling results previously mentioned. Minnesota followed the 4-step interstate transport framework and used an analytic year of 2023 to describe Minnesota's lack of contributions to out of state receptors and assess emission reduction considerations.

April 1, 2019 – This is 6 months after EPA received the Minnesota SIP submission and is the date that the CAA deems the Minnesota submittal to have been complete since EPA did not take action otherwise.

September 13, 2019 - The D.C. Circuit issued a decision in *Wisconsin v. EPA*, remanding the CSAPR Update to the extent that it failed to require upwind states to eliminate their significant

---

[73] **Completeness Finding** - Pursuant to the CAA Section 110(k)(1)(B) "Within 60 days of the Administrator's receipt of a plan or plan revision, but no later than 6 months after the date, if any, by which a State is required to submit the plan or revision, the Administrator shall determine whether the minimum criteria established pursuant to subparagraph (A) have been met. Any plan or plan revision that a State submits to the Administrator, and that has not been determined by the Administrator (by the date 6 months after receipt of the submission) to have failed to meet the minimum criteria established pursuant to subparagraph (a), shall on that date be deemed by operation of law to meet such minimum criteria."

contribution by the next applicable attainment date by which downwind states must come into compliance with the NAAQS, as established under CAA section 181(a). 938 F.3d at 313.

April 1, 2020 – This is 12 months after the completeness date and is the deadline for EPA to have acted on the MN SIP submission. Upon this deadline a full, partial or conditional approval was required by CAA Section 110(k)(2), (3), or (4).[74]

May 19, 2020 - the D.C. Circuit issued a decision in *Maryland v. EPA* that cited the Wisconsin decision in holding that EPA must assess the impact of interstate transport on air quality at the next downwind attainment date, including Marginal area attainment dates, in evaluating the basis for EPA's denial of a petition under CAA section 126(b). Maryland v. EPA, 958 F.3d 1185, 1203-04 (D.C. Cir. 2020). The court noted that "section 126(b) incorporates the Good Neighbor Provision," and, therefore, "EPA must find a violation [of section 126] if an upwind source will significantly contribute to downwind nonattainment at the next downwind attainment deadline. Therefore, the agency must evaluate downwind air quality at that deadline, not at some later date." Id. at 1204 (emphasis added). EPA interprets the court's holding in Maryland as requiring the states and the Agency, under the good neighbor provision, to assess downwind air quality as expeditiously as practicable and no later than the next applicable attainment date, which is now the Moderate area attainment date under CAA section 181 for ozone nonattainment. The Moderate area attainment date for the 2015 ozone NAAQS is August 3, 2024. At the time of the statutory deadline to submit interstate transport SIPs (October 1, 2018), many states relied upon EPA modeling of the year 2023, and no state provided an alternative analysis using a 2021 analytic year (or the prior 2020 ozone season). However, EPA must act on SIP submittals using the information available at the time it takes such action. In this circumstance, EPA does not believe it would be appropriate to evaluate states' obligations under CAA section 110(a)(2)(D)(i)(I) as of an attainment date that is wholly in the past, because the Agency interprets the interstate transport provision as forward looking. See 86 FR at 23074; see also Wisconsin, 938 F.3d at 322. Consequently, in this proposal EPA will use the analytical year of 2023 to evaluate each state's CAA section 110(a)(2)(D)(i)(I) SIP submission with respect to the 2015 ozone NAAQS.

May 12, 2021 – Downwinders at Risk, et al filed Case No. 21 Civ. 21 Civ 3551 asserting that EPA failed to undertake certain non-discretionary duties under the CAA.

---

[74] **Deadline for Action**. – Pursuant to the CAA Section 110(k)(1)(B) "Within 12 months of a determination by the Administrator (or a determination deemed by operation of law) under paragraph (1) that a State has submitted a plan or plan revision (or, in the Administrator's discretion, part thereof) that meets the minimum criteria established pursuant to paragraph (1), if applicable (or, if those criteria are not applicable, within 12 months of submission of the plan or revision), the Administrator shall act on the submission in accordance with paragraph (3)."

February 22, 2022 - EPA assessed the Minnesota submittal and on February 22, 2022 (3 years, 4+ months after submittal) the agency proposed denial of the Minnesota SIP as follows: "Based on EPA's evaluation of Minnesota's SIP submission and after consideration of updated EPA modeling using the 2016-based emissions modeling platform, EPA is proposing to find that the portion of Minnesota's October 1, 2018 SIP submission addressing CAA section 110(a)(2)(D)(i)(I) does not meet the state's interstate transport obligations for 2015 ozone NAAQS, because it fails to contain the necessary provisions to eliminate emissions that will contribute significantly to nonattainment or interfere with maintenance of the NAAQS in any other state. Air Plan Disapproval; Illinois, Indiana, Michigan, Minnesota, Ohio, Wisconsin; Air Plan Disapproval; Region 5 Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 87 Fed. Reg. 9838 (Feb. 22, 2022).

February 28, 2022 – EPA and Downwinders et al established in a Consent Decree entered into on 1/12/2022 that if EPA proposed a full or partial denial of the Minnesota SIP EPA shall have until December 15, 2022 to sign a final action. Note this is a settlement and does not erase the fact that EPA failed to complete its non-discretionary duty to have reviewed and acted upon the MN SIP by April 1, 2020.

April 30, 2022 – EPA and Downwinders, et established in a Consent Decree entered into on 1/12/2022 that required EPA to sign for publication final rulemaking on April 30, 2022 to approve, disapprove, and conditionally approve the Minnesota SIP submissions for the 2015 ozone NAAQS.

May 22, 2022 – EPA proposed to approve most elements of the Minnesota October 1, 2018 submission intended to address all applicable infrastructure requirements for the 2015 NAAQS. (87 FR 31462).

July 29, 2022 – EPA approved most elements of the Minnesota October 1, 2018 SIP submission from Minnesota regarding infrastructure requirements for the 2015 ozone NAAQS. EPA did not act on the interstate transport requirements and visibility impairments requirements. (87 FR 45663).

December 8, 2022 – EPA and Downwinders et al filed a Joint Motion of Stipulated Extension of Consent Decree deadlines that provided the following schedule.

December 15, 2022 – Former agreed upon deadline by Downwinders for EPA to act on Minnesota SIP, but this deadline was moved by agreement to January 31, 2022.

January 31, 2023 - deadline to sign final action on Minnesota SIP pursuant to agreed upon extension of Downwinders Consent Decree.

February 13, 2023 – EPA publishes final disapproval of State Implementation Plan (SIP) submissions for 19 states, including Minnesota. Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 FR 9336.

March 15, 2023 – EPA issues final federal Good Neighbor Plan for the 2015 ozone NAAQS (publication in the Federal Register is still pending).

Attachment B

(2018 SIP)

Infrastructure/110(a) requirements for the 2015 Ozone National Ambient Air Quality Standard

This State Implementation Plan (SIP) revision addresses the infrastructure requirements of sections 110(a)(1) and 110(a)(2) of the Clean Air Act (CAA) in regards to the National Ambient Air Quality Standards (NAAQS) for ozone, promulgated in 2015.

Contents

Introduction

The Minnesota Pollution Control Agency (MPCA) is, via submission of this document, requesting the revision of Minnesota's State Implementation Plan (SIP) under Sections 110(a)(1) and 110(a)(2), as well as Section 128 [as they are related to Section 110(a)(2)(E)(ii)] of the Clean Air Act (CAA). Sections 110(a)(1) and 110(a)(2) of the Act require that states prepare and submit to the U. S. Environmental Protection Agency (EPA) an "infrastructure" SIP (iSIP) within three years of the EPA's issuance of a new National Ambient Air Quality Standard (NAAQS) to demonstrate their continued ability to implement, maintain, and enforce the revised standards. Infrastructure SIP elements include requirements for limiting the interstate transport of air pollution under Section 110(a)(2)(D)(i)(I), commonly called "good neighbor requirements." Section 128 of the CAA mandates that members of boards governing state agencies that implement the Act represent the public interest and disclose any conflict of interest. This iSIP submittal addresses the 2015 ozone NAAQS revision.

The majority of this iSIP revision was written based on EPA's September 12, 2013 guidance document regarding multi-pollutant iSIPs, "Guidance on Infrastructure State Implementation Plan (SIP) Elements under Clean Air Act Sections 110(a)(1) and 110(a)(2)". The 2013 guidance did not address good neighbor elements.

Section 110(a)(2)(D)(i)(I) requires that states ensure that emissions within the state do not contribute significantly to nonattainment in, or interfere with maintenance by, any other state. This requirement means that Minnesota must show that emissions from within its borders are not significantly contributing to air pollution problems or violations in other states. In order to address the good neighbor requirements of this iSIP revision, MPCA referred to EPA's March 27, 2018 memo, "Information on the Interstate Transport State Implementation Plan Submissions for the 2015 Ozone National Ambient Air Quality Standards under Clean Air Act Section 110(a)(2)(D)(i)(I)". Appendices B and C of the 2018 memo, and associated May 18, 2018 updates to modeling activities, provided states with modeled downwind contribution results for receptors that EPA expects will be nonattainment or maintenance areas in 2023. MPCA used the results of EPA's modeling exercise, in addition to modeling conducted by the Lake Michigan Air Directors Consortium (LADCO), to affirm that Minnesota does not contribute to any downwind receptors above the one percent threshold used by EPA to determine significant impact.

The iSIP below discusses each Section under 110(a) and provides information on how Minnesota meets the requirements for each. Based on information set forth in the 2013 guidance, the 2018 memo, previously approved iSIP submittals, and conversations with Region 5 staff, the MPCA believes that this iSIP submittal meets all of the requirements of CAA Sections 110(a)(1) and 110(a)(2).

Section 110(a)(1): A plan which provides for implementation, maintenance, and enforcement

The Minnesota Pollution Control Agency (MPCA) has, in prior submittals, documented its authority and ability to provide for the implementation, maintenance, and enforcement of primary and secondary air quality standards, as well as to adopt enforceable emission limitations and control measures to meet the primary and secondary standard and to update both state rules and the SIP, as necessary.

Various Minnesota statutes, addressed below, authorize the MPCA to adopt air quality standards.

Minn. Statute § 116.07, subd. 2(a) states:

> "The agency shall improve air quality by promoting, in the most practicable way possible, the use of energy sources and waste disposal methods which produce or emit the least air contaminants consistent with the agency's overall goal of reducing all forms of pollution. The agency shall also adopt standards of air quality…, recognizing that due to variable factors, no single standard of purity of air is applicable to all areas of the state…"

Minn. Stat. § 116.07, subd. 4(a), authorizes the agency to "…adopt, amend and rescind rules and standards having the force of law relating to any purpose… for the prevention, abatement, or control of air pollution…"

Under Minn. Stat. 116.07 § subd. 9, the MPCA is granted the authority to enter into or enforce orders, schedules of compliance, and stipulation agreements; to require owners or operators of emission facilities to install and operate monitoring equipment and to conduct tests; and to conduct investigations, issue notices, and order hearings, as deemed necessary, to discharge the MCPA's duties.

Minn. Stat. § 116.072 authorizes the MPCA to issue orders and assess administrative penalties to correct violations of the MPCA's statutes, rules, and permits. The statute also authorizes administrative penalties up to a maximum of $10,000 for all violations identified during an inspection or compliance review.

Minn. Stat. § 115.071, subd. 1 provides that violations of the MPCA's statutes, rules, standards, orders, stipulation agreements, schedules of compliance, and permits may be remedied with criminal prosecution, action to recover civil penalties, injunction, and action to compel performance, other appropriate action, or any combination of the above. Relatedly, Minn. Stat. § 115.071, subd. 3 indicates that civil penalties may be recovered up to a maximum of $10,00 per day of violation, except for violations related to hazardous waste, the maximum for which is $25,000 per day of violation.

Minnesota's SIP-approved air quality rules are established under the above statutory authorities, and broadly cover the criteria pollutants listed, as defined in Minn. R. Ch. 7005.0100: "sulfur dioxide, particulate matter, nitrogen oxides, carbon monoxide, ozone, lead, and any other pollutants for which national ambient air quality standards have been established…" Primary and secondary ambient air quality standards are defined in Minn. R. Ch. 7009.0010 subp. 2 and 3; Minn. R. Ch. 7009.0020 prohibits emissions that cause or contribute to the violation of any ambient air quality standard. The NAAQS are incorporated by reference in Minn. R. Ch. 7009.0090.

We assert that the above statutory and regulatory authorities fulfill the requirements of Section 110(a)(1).

Section 110(a)(2)(A): Emission limits and other control measures

Minn. Stat. Ch. 116 gives the MPCA the authority to develop rules and regulations and also allows the MPCA to implement current rules and apply existing controls and emissions limits to help maintain new standards. Minn. Stat. § 116.07, subd. 4(a) gives the MPCA the authority to "adopt, amend and rescind rules and standards having the force of law relating to any purpose… for the prevention, abatement, or control of air pollution."

Minn. Stat. § 116.07, subd. 4a(a), gives the MPCA authority to "issue, continue in effect or deny permits, under such conditions as it may prescribe for the prevention of pollution, for the emission of air contaminants, or for the installation or operation of any emission facility, air contaminant treatment facility, treatment facility, potential air contaminant storage facility, or storage facility…"

Minnesota does not have any nonattainment or maintenance areas for the 2015 ozone NAAQS; however, there are methods in place to address emissions of nitrogen oxides (NO_x) and volatile organic compounds (VOCs), which are considered by EPA to be the primary precursors to ground-level ozone formation.

Nitrogen oxides (NO_x)

State rules that limit NO_x, as well as nitrogen dioxide (NO_2) emissions, include Minn. R. Ch. 7011.0500 through 7011.0553, which address Indirect Heating Fossil-Fuel-Burning Equipment, and Minn. R. Ch. 7011.1700 through 7011.1730, which address Nitric Acid Plants in Minnesota.

Volatile organic compounds (VOCs)

In order to minimize the formation of ground-level ozone, we limit the emissions of volatile organic compounds (VOCs), which are the primary ozone precursors, through our Part 70 permit program. In addition, Minnesota's state rules incorporate, by reference, the National Emission Standards for Hazardous Air Pollutants (NESHAPs), which, with Part 70 permits, limit VOC emissions. These limits help to protect the 2015 ozone NAAQS.

More information about emissions limits and other control measures can be found in the discussion of Section 110(a)(2)(D)(i)(I) of this document, which reviews Minnesota's interstate transport obligations.

We assert that the above statutory and regulatory authorities fulfill the requirements of Section 110(a)(2)(A).

Section 110(a)(2)(B): Ambient air quality monitoring/data system

Minnesota monitors for ambient ozone levels at 17 locations throughout the state. Minnesota's ambient air quality monitoring network is designed and operated to meet the requirements of 40 CFR Part 58, "Ambient air quality surveillance". Data from the monitors are submitted to the U.S Environmental Protection Agency's (EPA) Air Quality System (AQS) in a timely manner.

The MPCA completes an annual air monitoring network plan for the state, required under 40 CFR § 58.10, which describes the existing air monitoring network, as well as planned and proposed changes. These network plans are available on the MPCA's website, at https://www.pca.state.mn.us/air/air-monitoring-network-plan. The 2019 Annual Air Monitoring Network Plan for Minnesota was posted and available for public comment from May 1 through June 1, 2018, and will be submitted to EPA prior to the July 1, 2018 deadline. The 2019 plan includes a new Appendix D that describes the MPCA's Photochemical Assessment Monitoring Station (PAMS) Network Implementation Plan, which reflects changes in EPA's ambient ozone monitoring requirements that were made as part of the 2015 ozone NAAQS revision. The PAMS Network Implementation Plan has been tentatively approved by EPA per the early review of the 2019 plan.

Minn. Stat. § 116.07, subd. 9(b) gives the MPCA authority "to require the owner or operator of any emission facility, air contaminant treatment facility, potential air contaminant storage facility, or any system or facility related to the storage, collection transportation, processing, or disposal of waste… to install, use, and maintain monitoring equipment or methods…". Information about the industrial monitoring network in Minnesota is available in Appendix B of annual monitoring plan updates.

We assert that the above statutory requirements and associated ambient air quality monitoring practices at MPCA fulfill the requirements of Section 110(a)(2)(B).

Section 110(a)(2)(C): Programs for enforcement and for regulation of PSD and NSR

As described above, Minn. Stat. §§ 116.07, subd. 9, 116.072, and 115.071 give MPCA the authority to enforce any provisions of section 116 and the rules, standards, orders, stipulation agreements, schedules of compliance, and permits adopted or issued thereunder, or under any other law relating to air contamination.

These sections include, but are not limited to, the following authorities:

- Entering into orders
- Schedules of compliance
- Stipulation agreements
- Requiring owners or operators of emissions facilities to install and operate monitoring equipment
- Conduction of investigations

Minn. Stat. § 116.072 authorizes the MPCA to issue orders and assess administrative penalties to correct violations of MPCA's rules, statutes, and permits; Minn. Stat. § 115.071 outlines the remedies that are available to address such violations. Additionally, Minn. R. 7009.0030 and 7009.0040 provide for enforcement measures related to the violation of ambient air quality standards.

Minn. R. Ch. 7007 contains the requirements of the MPCA's permitting program, through which enforceable emission limitations are placed on facilities.

Minnesota previously used delegated authority, under 40 CFR § 52.21, to permit Prevention of Significant Deterioration (PSD) sources through a Federal Implementation Plan (FIP). On October 4, 2016, the MPCA submitted a SIP revision to incorporate new PSD rules, which incorporated federal PSD rules by reference in Minn. R. Ch. 7007.3000. EPA approved the SIP revision, and the new PSD rules, on September 26, 2017 (82 FR 44734); these rules have been incorporated into Minnesota's SIP at 40 CFR § 52.1220.

Although Minnesota does not have any nonattainment or maintenance areas for the 2015 ozone NAAQS, we have an approved nonattainment New Source Review (NSR) program, which was approved by EPA on May 24, 1995 (60 FR 27411). Minn. R. Ch. 7007.4000 through 7007.4030 incorporates, by reference, the NSR requirements specified in 40 CFR Part 51, Appendix S.

To address the pre-construction regulation of the modification and construction of minor stationary sources and minor modifications of major stationary sources, EPA approved Minnesota's minor NSR program on May 24, 1995 (FR notice citation). Since then, MPCA and EPA have relied on these existing provisions to ensure that new and modified sources not captured by the major NSR permitting programs do not interfere with attainment and maintenance of the ozone and other NAAQS.

We assert that the above statutory and regulatory authority fulfill the requirements of Section 110(a)(2)(C).

Section 110(a)(2)(D): Interstate transport provisions ("good neighbor SIPs")

Section 110(a)(2)(D)(i)(I): Prongs 1 (significant contribution to nonattainment) and 2 (interference with maintenance)

This section requires iSIPs to have provisions prohibiting sources from emitting air pollutants in amounts that would contribute significantly to nonattainment or interfere with maintenance in any other state. These interstate transport requirements are often referred to as "good neighbor SIPs". The analyses conducted to support the 2015 ozone good neighbor SIPs show Minnesota does not contribute significantly to air quality problems in any downwind nonattainment or maintenance area. Therefore, no additional controls or emissions limits are required to fulfill Minnesota's good neighbor obligations.

On March 27, 2018, the EPA published a memo, entitled "Information on the Interstate Transport State Implementation Plan Submissions for the 2015 Ozone National Ambient Air Quality Standards under Clean Air Act Section 110(a)(2)(D)(i)(I)" (Memo). The Memo built off another, published on October 27, 2017, which provided guidance to air agencies regarding the development of ozone interstate transport components of iSIPs for the 2008 ozone NAAQS.

EPA's Memo includes new transport modeling data for the year 2023 (the Moderate Attainment deadline for the 2015 ozone NAAQS). These data are provided to assist states in completing the "good neighbor" SIPs for the 2015 ozone NAAQS, and to thereby address interstate transport obligations.

EPA identifies a four-step framework in the Memo, intended to guide states on how to go about developing good neighbor SIPs:

1. Identify downwind air quality problems;
2. Identify upwind states that contribute enough to those downwind air quality problems to warrant further review and analysis;
3. Identify the emissions reductions necessary (if any), considering cost and air quality factors, to prevent an identified upwind state from contributing significantly to those downwind air quality problems; and
4. Adopt permanent and enforceable measures needed to achieve those emissions reductions.

EPA and states have applied this four-tiered approach, shaped by public notice and comment and refined in response to court decisions, to address good neighbor obligations for previous NAAQS revisions.

1. Identify downwind air quality problems

In the Memo, EPA identifies parts of the country projected to have difficulty attaining or maintaining the 2015 ozone NAAQS by the 2023 moderate attainment deadline. To extrapolate ozone design values (DVs) to 2023, EPA used the Comprehensive Air Quality Model with Extensions (CAMx v6.40) to model 2011 and 2023 emissions. EPA used the outputs from the 2011 and 2023 model simulations to create relative response (of air quality to emission changes) factors. EPA applied the relative response factors to project base period 2009-2013 average and maximum ozone DVs to 2023 at monitoring sites across the country. EPA used the projected future year DVs to identify potential 2023 nonattainment and maintenance receptors for the 2015 ozone NAAQS.

In projecting future year DVs, EPA applied its own modeling guidance and an alternative approach suggested during the January 2017 notice of data availability comment period and backed by other relevant analyses. The alternative excludes from the analysis grid cells positioned over water from the 3 x 3 array of model grid cells surrounding monitoring sites in coastal areas. In the upper Midwest, excluding grid cells positioned over water projects Milwaukee Wisconsin (monitoring site 550790085) as a downwind nonattainment receptor. This means EPA expects the Milwaukee site may have difficulty meeting the ozone NAAQS in 2023 without additional control measures applied in culpable States. Including model grid cells over water projects the Milwaukee site as an attainment receptor. This perspective means the Milwaukee site may achieve ozone design values below the NAAQS without additional controls beyond those addressed in the modeled projections.

The Memo outlines possible alternatives when modeling interstate transport. The Lake Michigan Air Directors Consortium (LADCO), a multi-jurisdictional organization comprised of EPA Region V States, provides modeling support for those states, including Minnesota. LADCO has conducted modeling[1] incorporating alternative bullet #4 in the Memo Analytics section to support 2015 ozone good neighbor SIPs.

Specifically, LADCO replicated EPA's 2023EN platform with the exception of substituting Eastern Regional Technical Advisory Committee (ERTAC) [2] EGU estimates for EPAs engineering analysis estimates. The MPCA believes power sector emissions forecasts must address economic factors, preserve system reliability, and include controls or emission reduction measures justified through some legal framework. It is our understanding that the engineering analysis used by EPA to project EGU emissions to 2023 (version EN of the modeling platform) does not comply with these key requirements. The ERTAC estimates incorporate the key requirements. Table 1 outlines the primary differences between the EPA "engineering analysis" and ERTAC handling of the key requirements. The incorporation of ERTAC in the model simulation produces some new, and changes the status of some, nonattainment or maintenance receptors downwind of Minnesota. Tables 2 and 3 (columns 3 through 6) show the differences.

Table 1. Primary differences between EPA's engineering analysis and LADCO's ERTAC analysis.

Key requirement	EPA engineering analysis	ERTAC
Economic factors	Minimal Economic factors considered. No growth from 2016 to 2023.	Complex growth algorithm based on Annual Energy Outlook (AEO) projections for annual growth and North American Electric Reliability Corporation (NERC) for peak day growth. Growth applied by fuel type and region based on AEO splits.
Preservation of system reliability	No implicit check for reliability.	Complex set of algorithms check system wide capacity against the demand plus safety margins to verify if there is a lack of generation in a region.
Controls or emission reduction measures justified through a legal framework	Applied emission reductions by optimizing existing controls that in 2016 were not optimized without justification the controls will be optimized.	Only applied emission reduction estimates with justification.

2. Upwind states' contributions to downwind air quality problems

EPA has previously determined that a state contribution to downwind air quality problems below one percent of the applicable NAAQS is insignificant. This screening method was used in previous good neighbor SIP approvals, including (most notably) the Cross-State Air Pollution Rule (CSAPR), and the CSAPR update for the 2008 ozone NAAQS and 2012 NAAQS for particulate matter less than 2.5 micrometers in diameter ($PM_{2.5}$). The one percent screening method was developed through several previous federal notice and comment rulemakings. One percent of the 2015 ozone NAAQS (70 ppb) is 0.70 ppb. Therefore, any state that contributes less than 0.70 ppb to a projected nonattainment or maintenance area in another state is not culpable for those air quality problems.

EPA and LADCO implemented the Anthropogenic Precursor Culpability Analysis (APCA) technique in CAMx to identify upwind states culpable for downwind ozone air quality problems. The method accounts for human-made nitrogen oxides (NO_x) and volatile organic carbon (VOC) emissions from all sources in each upwind state affecting projected 2023 ozone concentrations at each downwind air quality monitoring site designated a nonattainment or maintenance receptor. EPA and LADCO conducted the culpability analysis for the period May 1 through September 30, using the 2023 future emission estimates and 2011 meteorology. Refer to pages 5 and 6 of the Memo for more information regarding EPA's culpability analysis.

---

[1] See Attachment 1, "Interstate Transport Modeling for the 2015 Ozone National Ambient Air Quality Standard: Technical Support Document". The TSD includes text about excluding data from the design value calculation based on model performance. The data in this iSIP, Tables 2 and 3, do not reflect this feature.
[2] See Attachment 2, "Documentation of ERTAC EGU CONUS Versions 2.7 Reference and CSAPR Update Compliant Scenario".

Both analyses conclude Minnesota is not culpable for ozone nonattainment, or interference with maintenance, in any downwind states. As shown in Table 2, EPA's analysis indicates Minnesota contributes most to Milwaukee, Wisconsin monitor site 550790085. At a concentration of 0.40 ppb, this contribution is roughly equal to 0.57% of the 2015 ozone NAAQS (70 ppb). LADCO's analysis corroborates EPA's results, showing a concentration of 0.45 ppb, roughly equal to 0.64% of the NAAQS.

While there are some differences in the list of receptors identified as nonattainment or maintenance receptors between the EPA and LADCO modeling exercises, there are no significant differences in Minnesota's contribution to any of the receptors identified by either EPA or LADCO. Although Minnesota 2023 emission estimates with ERTAC are lower than the EPA engineering analysis estimates, Minnesota's downwind culpability remains the same – negligible – as shown in Tables 2 and 3.

Table 2. Minnesota's projected 2023 ozone contributions, from human-made NO_x and VOC emissions, to states with nonattainment or maintenance receptors, based on the "no water" alternative. Source of EPA model data: "March 2018 Memo and Supplemental Information Regarding Interstate Transport SIPs for the 2015 Ozone NAAQS", https://www.epa.gov/airmarkets/march-2018-memo-and-supplemental-information-regarding-interstate-transport-sips-2015; these data include the May 18, 2018 updates. ERTAC-substituted model and data sourced from LADCO – see Attachments 1 and 2. Values in gray did not exceed the 70 ppb modeling threshold used to identify projected 2023 nonattainment or maintenance areas.

*The Richmond, NY site was first included by EPA in the March 27 memo, as it was shown to be a nonattainment receptor in the "water" modeling approach. See Table 3 for projected DV information.

Table 3 shows the list of receptors EPA identified in Appendix B of the Memo using the "water" (non-alternative) cell approach. EPA did not identify state-by-state contributions for this approach, but we include those receptors here for comparison to LADCO's modeling.

Table 3. Minnesota's projected 2023 ozone contributions, from human-made NO_X and VOC emissions, to states with nonattainment or maintenance receptors, based on the "water" alternative. Source of EPA model data: Memo, Attachment B, "Projected ozone design values at potential nonattainment and maintenance receptors based on EPA's updated 2023 transport modeling", p. B-3. Updates to these values were not provided with the other May 18, 2018 updates under the "no water" alternative. ERTAC-substituted model and data sourced from LADCO – see Attachments 1 and 2. Values in gray did not exceed the 70 ppb modeling threshold used to identify projected 2023 nonattainment or maintenance areas.

*Although EPA modeled projected ozone values and identified potential nonattainment and maintenance receptors for both the "water" and "no water" alternatives, EPA did not provide state-by-state contributions to the 2023 8-hour ozone DVs for the "water" scenario in Appendix C or the excel files accompanying the Memo.
**Although the Milwaukee, WI site was not identified as a potential nonattainment or maintenance receptor by either EPA or LADCO under the "water" alternative, we've included it here to demonstrate that it is still the receptor for which Minnesota's contribution is highest.

LADCO's analyses have, in addition to EPA's, concluded that Minnesota is not culpable for ozone nonattainment, or interference with maintenance, in any downwind states.

3. Identify emissions reductions necessary (if any)

Neither the EPA or the LADCO analyses identified any potential nonattainment or maintenance receptors significantly impacted by ozone transport from Minnesota in 2023. For previous good neighbor SIP submittals, the EPA has relied on a one percent threshold to determine significant downwind contributions of regional pollutants. As stated previously and shown in Tables 1 and 2, the highest contribution from Minnesota modeled by EPA and LADCO was at Site 550790085 in Milwaukee, WI; all models showed our contributions to be significantly below the one percent (0.70 ppb) threshold for the 2015 ozone NAAQS. Therefore, Minnesota does not have a responsibility to identify or implement any further controls or emissions limits to reduce downwind ozone contribution.

The following information provides strengthening evidence to the above modeling analysis.

Ambient ozone concentrations in Minnesota

Minnesota has never been in nonattainment for any promulgated ozone NAAQS, and ambient ozone concentrations in Minnesota have consistently been near or below the NAAQS. Figure 1 shows ozone concentrations as a percent of the NAAQS for each given year. Figure 1 shows data starting in 1997, which was the year that the form of the standard changed to represent the "annual fourth-highest daily maximum 8-hr concentration, averaged over 3 years". This continues to be the current form, although the level of the standard has been lowered twice since that first change.

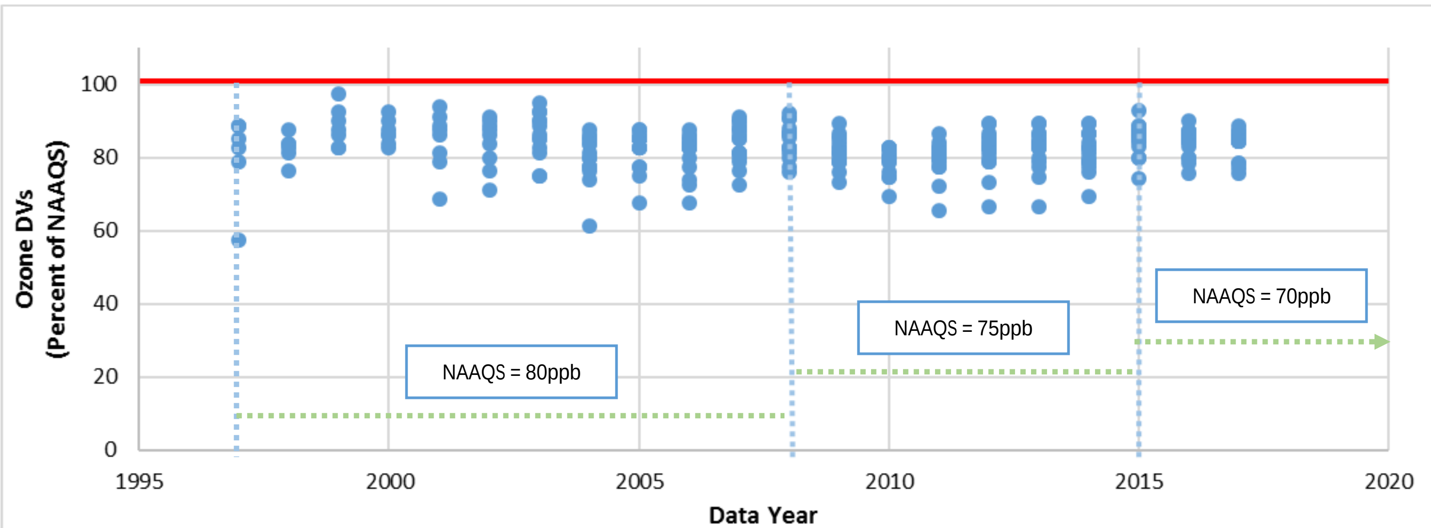

Figure 1. 8-hour (annual fourth-highest daily maximum 8-hr concentration, averaged over 3 years) ozone DVs from Minnesota ambient ozone monitors, shown as percentage of NAAQS, from 1997-2017. Although monitors throughout the state show a range of ambient concentration values, Minnesota has never had an exceedance of any promulgated ozone NAAQS.

As discussed above in Section 110(a)(2)(B), there are currently 17 ozone monitors located throughout the state. Monitoring data from 2015-2017, as shown in Figure 2, indicate that the highest ozone concentration is at Site 27-003-1002, the Anoka Airport in Blaine. At 62ppb, the 2015-2017 DV was at approximately 89 percent of the 70ppb NAAQS.

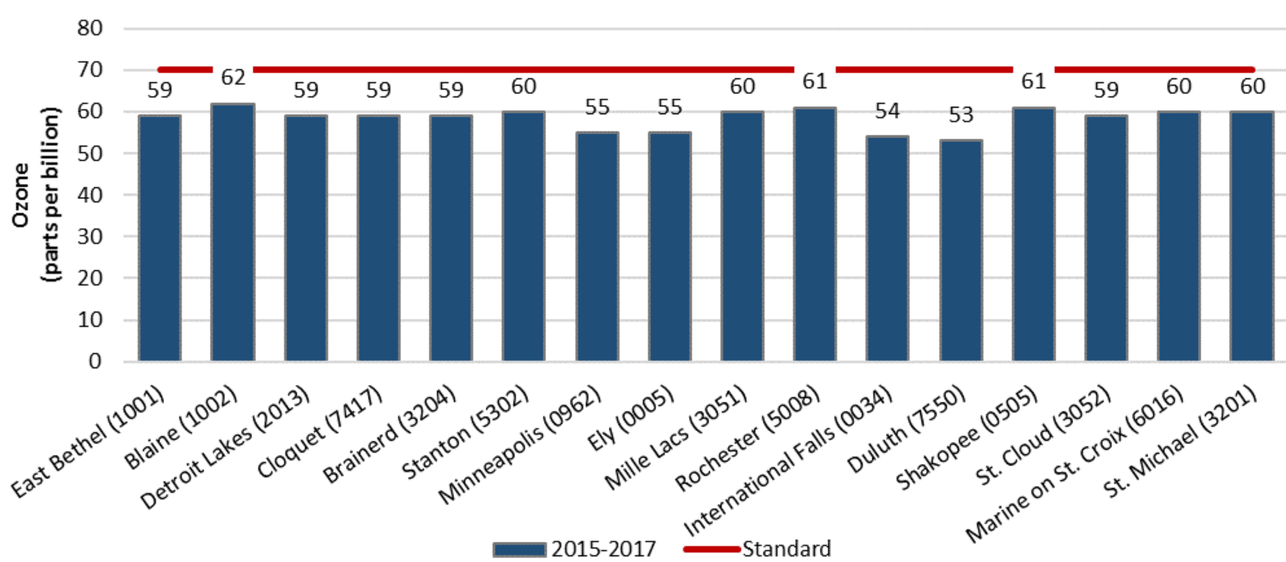

Figure 2. 8-hour average ozone concentrations compared to the 2015 ozone NAAQS, 2015-2017

Minnesota's ambient ozone concentrations are steadily decreasing; it would be reasonable to assume that Minnesota is, therefore, contributing less to ozone concentrations in other states.

Nitrogen oxides (NO_x) and volatile organic compound (VOC) emissions in Minnesota

When conducting modeling with the CAMx APCA platform, EPA identified anthropogenic (human-made) NO_x and VOCs as the primary precursors to ground-level ozone formation. Thus, we will focus our discussion of emissions reductions in Minnesota on NO_x and VOC emissions data.

NO_x emissions have been steadily declining in Minnesota over the past several years. Figure 3 demonstrates the steady decline of emissions from point (permitted), non-point (neighborhood), on-road mobile, and non-road equipment. The largest reductions in emissions have come as a result of emissions limits and reductions at point sources, particularly electric generating utilities (EGUs). Point source emissions reporting is required annually.

Every three years MPCA collects expanded emissions inventories from non-point, on-road, and mobile sources, and works with EPA to identify emissions categories and to verify state-collected data, if necessary. NO_x emissions from these traditionally non-permitted sources have also been declining, though less rapidly than for point sources.

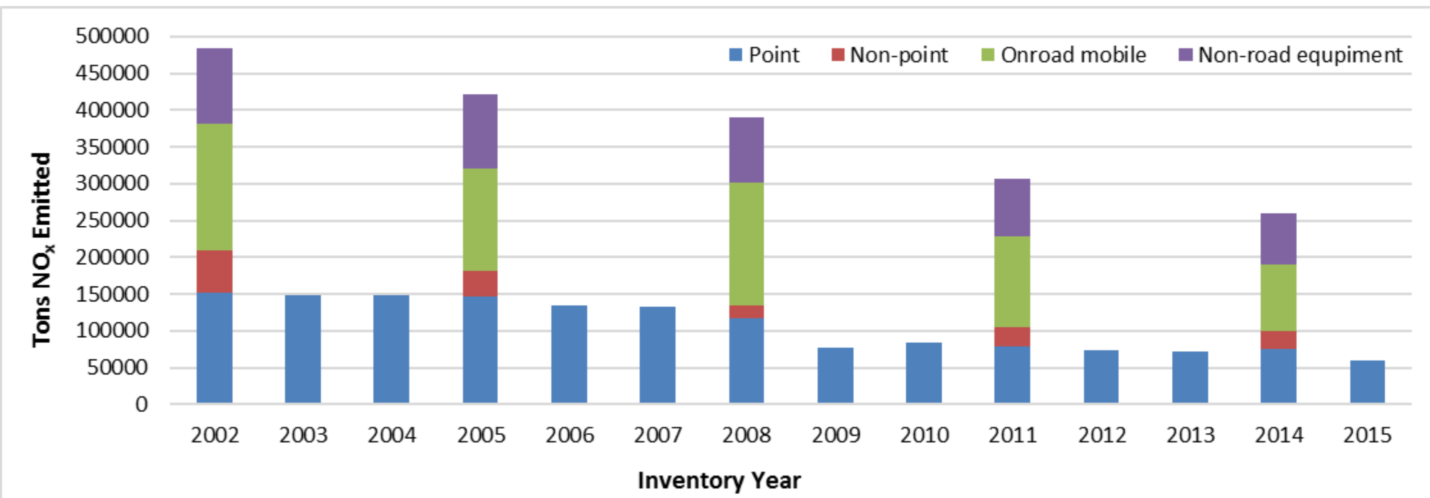

Figure 3. Reported (actual) NO_x emissions for the state of Minnesota, 2002-2015. Inventory data for 2014 are preliminary.

As with NO_x emissions, VOC emissions have been steadily declining in Minnesota over the past several years. Figure 4 shows emissions from point (permitted), non-point (neighborhood), on-road mobile, and non-road equipment.

Again, as with NO_x, MPCA collects expanded emissions inventories from non-point, on-road, and mobile sources every three years. Although some VOC emission reductions have resulted as a co-benefit of emissions limits on point sources, the majority of VOC emission reductions in recent years has come from lower on-road mobile source emissions, primarily through Minnesotans' use of cleaner, more fuel efficient vehicles.

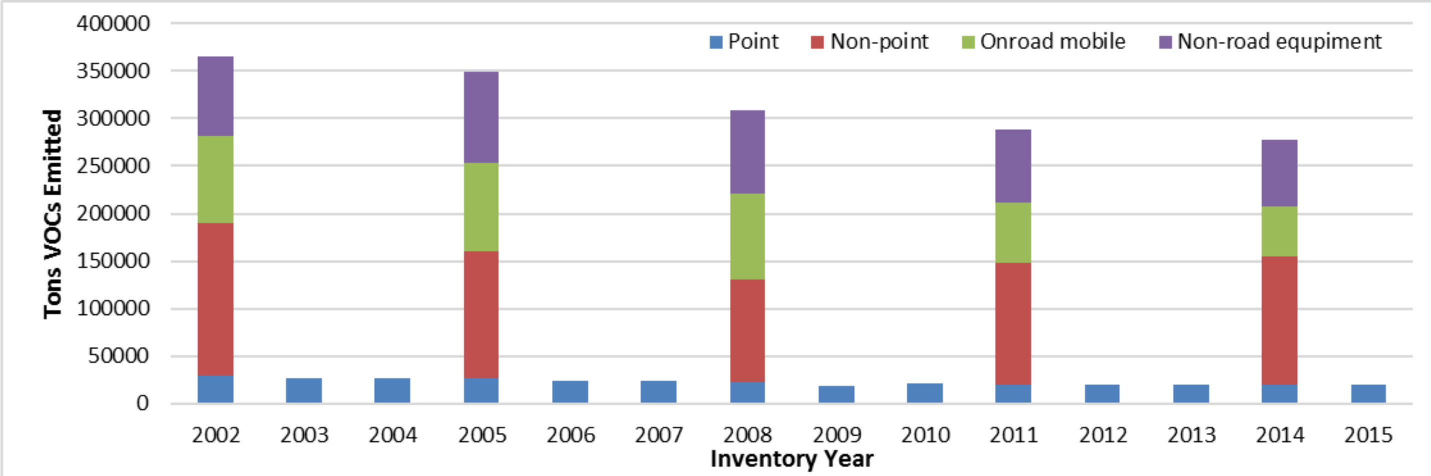

Figure 4. Reported (actual) VOC emissions for the state of Minnesota, 2002-2015. Inventory data for 2014 are preliminary.

4. Adopt permanent and enforceable measures needed to achieve reductions identified in item 3.

Since NO_x and VOC emissions in Minnesota continue to decrease, ozone formation is also declining; ozone is not directly emitted by any sources. This, in combination with the fact that Minnesota is not expected to contribute to any nonattainment or maintenance issues downwind by the year 2023, makes it such that no additional permanent or enforceable measures, beyond those already implemented in the state, are needed at this time.

Current measures that limit emissions of these pollutants and therefore help maintain Minnesota's insignificant contribution to downwind air quality concerns are discussed below.

Multi-pollutant limits

Minnesota has several methods of limiting emissions from facilities in the state. The primary way in which emissions of NO_x and VOCs are limited in Minnesota is through emissions limits described in Part 70 permits.

Minnesota is subject to CSAPR's annual NO_x programs, which were developed to address the 1997 and 2006 $PM_{2.5}$ NAAQS. The CSAPR regulations have resulted in a reduction of NO_x emissions from power plants subject to the rule (see Figure 3, above). In addition, many of Minnesota's coal-fired boilers have been converting to natural and/or fuel gas over the past several years, in response to state regulations to reduce mercury emissions (Mercury Emissions Reduction Act of 2006), as well as more recent Mercury and Air Toxics Standards (MATS). Although intended to reduce mercury emissions, these regulations have also resulted in reductions in co-pollutants, like NO_x and SO_2.

Pollutant-specific limits

Minnesota has, in addition to multi-pollutant limits, pollutant-specific methods of limiting emissions. Most of our pollutant-specific limits are for SO_2 and particulate matter, as those are the two pollutants for which we have had nonattainment (and subsequently, maintenance) areas.

NO_x

State rules that limit NO_x and NO_2 emissions include:

- Minn. R. Ch. 7011.0500 to 7011.0553, for Indirect Heating Fossil Fuel Burning Equipment

- Minn. R. Ch. 7011.1700 to 7011.1705, for Nitric Acid Plants

Minnesota has issued an Administrative Order (AO) to Xcel Energy – Northern States Power Company, Sherburne County Generating Station, as part of Minnesota's Regional Haze SIP. The AO includes NO_x emissions limits.

VOCs

The majority of VOC emissions in Minnesota come from nonpoint (neighborhood) and small point sources. Minnesota's state rules incorporate, by reference, the National Emission Standards for Hazardous Air Pollutants (NESHAPs), which limit VOC emissions. The primary method by which we limit VOC emissions is through the issuance of Part 70 permits and Title I emissions limits in permits, which can help small sources avoid classification as major sources when unnecessary.

The MPCA has statewide partnerships with non-profit organizations, the University of Minnesota, state contractors, and local governments to promote the voluntary reduction of VOCs through education programs and the administration of grants to small businesses, particularly auto body and coating shops.

Summary: Prongs 1 and 2

It can be reasonably concluded from the above analyses that Minnesota does not, and will not by 2023, significantly contribute to nonattainment or interfere with maintenance of the 2015 ozone NAAQS at any of EPA's identified receptors. Minnesota has not historically contributed significantly to any of the monitors projected to have nonattainment or maintenance issues in 2023. Our emissions of ozone precursors, NO_x and VOCs, are on a downward trend, and our emissions sources currently have limits and controls that will continue to reduce ozone concentrations via a reduction in precursors.

EPA's own modeling showed a downwind contribution of less than one percent at all examined receptors, which has historically been accepted as a demonstration that ozone transport will not affect any nonattainment or maintenance receptors, as identified, for the year 2023.

It follows that the limits and controls that Minnesota already has in place across the state are sufficient to make it reasonably certain that Minnesota will not significantly contribute to nonattainment or interfere with maintenance in any other state. We assert that no further controls or emissions limits are required to fulfill our responsibilities under the interstate transport provisions for the 2015 ozone NAAQS under prongs 1 and 2 of Section 110(a)(2)(D)(i)(I).

Section 110(a)(2)(D)(i)(II): Prongs 3 (interference with PSD) and 4 (interference with visibility protection)

This section requires iSIPs to include provisions prohibiting any source or other type of emissions activity in one state from interfering with measures required to prevent significant deterioration of air quality or the protection of visibility in another state.

As mentioned above, Minnesota has recently had its PSD program (at Minn. R. Ch. 7007.3000) approved into the SIP at 40 CFR § 52.1220, and so continues to operate a federally-approved nonattainment NSR (NNSR) permitting program. Thus, all new major sources and major modifications are subject to a comprehensive, EPA-approved permitting program that applies to all NSR pollutants. These programs require the consideration of emission impacts on the air quality of other states. Minn. R. Ch. 7007.0900 provides for the review of Part 70 permits by affected states.

Minnesota does not have any nonattainment areas for the 2015 ozone NAAQS; however, NNSR rules have been promulgated, and are contained in Minn. R. Ch. 7007.4000-7007.4030. These rules ensure that, if there ever is an instance where an area in the state becomes nonattainment, the sources located in those areas would not interfere with neighboring states' PSD programs.

EPA approved significant portions of Minnesota's Regional Haze (RH) SIP on June 12, 2012 (77 FR 34801); however, due to the disapproval of various components, Minnesota is currently subject to a Federal Implementation Plan (FIP) for unapproved sources. Sources that are within Minnesota's jurisdiction – that that were approved in the RH SIP – are not interfering with neighboring states' abilities to protect visibility. Visibility in the two Class I areas within the state of Minnesota continues to improve, as well. Interim visibility goal targets, which show 2018 as a target year, are being met in both locations.

Based on our discussed PSD and RH program components, we assert that Minnesota meets the requirements of prongs 3 and 4 of Secion 110(a)(2)(D)(i)(II).

Section 110(a)(2)(D)(ii): Interstate pollution abatement and international air pollution

Minnesota administers a federally-approved PSD program through Minn. R. Ch. 7007.3000, which incorporates, by reference, 40 CFR § 52.21. Subsequently, new or modified sources are required to notify neighboring states of potential negative air quality impacts. Our previous iSIP submittal for this section was disapproved due to the underlying issues with the PSD program. Now that Minnesota's PSD program has been approved, we assert that Minn. R. Ch. 7007.3000 fulfills the requirements of Section 110(a)(2)(D)(ii), as well as interstate pollution abatement requirements under Section 126(a). Minnesota has no other obligations under Section 126, nor under the international pollution abatement components of Section 115.

We assert that the above regulatory authority fulfills the requirements of Section 110(a)(2)(D)(i)(II).

Section 110(a)(2)(E): Adequate resources and authority, conflict of interest, and oversight of local governments and regional agencies

Per Minn. St. § 116.07, the MPCA is granted the authority and responsibility for developing, implementing, and enforcing rules that allow Minnesota to comply with the Clean Air Act (CAA), including maintenance of the SIP. MPCA's Performance Partnership Agreement (PPG) with EPA provides MPCA the assurances to the availability of resources needed to carry out certain air programs.

MPCA's authority to enforce the NAAQS has been demonstrated previously in this document.

Minnesota's satisfaction of section 110(a)(2)(E)(ii), as it relates to state board requirements of Section 128, is discussed near the end of this document. The rules submitted in this iSIP in order to meet the requirements of Section 128 also satisfy any applicable requirements related to section 110(a)(2)(E)(ii) for the 2015 ozone NAAQS. To the extent that the state board requirements are non-NAAQS specific, we request that EPA also approve these rules as satisfying the applicable Section 110(a)(2)(E)(ii) requirements for any NAAQS for which final action has not been taken.

We assert that the above statutory authority, in tandem with that presented below for Section 128, fulfills the requirements of Section 110(a)(2)(E).

Section 110(a)(2)(F): Stationary source monitoring and reporting

Minn. Stat. § 116.07, subd. 9(b) gives the MPCA authority "to require the owner or operator of any emission facility, air contaminant treatment facility, potential air contaminant storage facility, or any system or facility related to the storage, collection transportation, processing, or disposal of waste... to install, use, and maintain monitoring equipment or methods...".

Minn. R. Ch. 7007.0800, subp. 4 describes the minimum monitoring requirements included in each permit for major stationary sources. Minn. R. Ch. 7011, which includes standards for stationary sources, also lists monitoring requirements for each applicable source category.

Minn. R. Ch. 7017 contains Minnesota's air monitoring and testing requirements, including for continuous monitoring.

Minn. R. Ch. 7019 contains emissions reporting requirements for applicable facilities, which must submit annual emissions inventories to MPCA. The inventory reports must contain information on all criteria pollutants for which a NAAQS has been promulgated. The MPCA also collects emissions inventory for air toxics, including VOCs, on a triennial basis.

The majority of applicable rules in Chs. 7007, 7011, 7017, and 7019 have been previously approved by EPA and subsequently incorporated into Minnesota's SIP at 40 CFR § 52.1220.

We assert that the above statutory and regulatory authorities fulfill the requirements of Section 110(a)(2)(F).

Section 110(a)(2)(G): Emergency episodes

Although historic ambient monitoring data does not indicate a need for specific contingency measures for ozone, Minn. Stat. § 116.11 was promulgated to allow the MPCA to halt or abate specific sources of pollution during an emergency.

Minn. Stat. § 116.11 reads:

> "If there is imminent and substantial danger to the health and welfare of the people of the state, or of any of them, as a result of the pollution of air, land, or water, the agency may by emergency order direct the immediate discontinuance or abatement of the pollution without notice and without a hearing or at the request of the agency, the attorney general may bring an action in the name of the state in the appropriate district court for a temporary restraining order to immediately abate or prevent the pollution. The agency order or temporary restraining order shall remain effective until notice, hearing, and determination pursuant to other provisions of law, or, in the interim, as otherwise ordered. A final order of the agency in these cases shall be appealable in accordance with chapter 14."

Minn. R. Ch. 7000.5000 elaborates on specific actions to be taken to notify and communicate about any emergency declared by the commissioner. Further instruction and requirements for owners and operators of any facility or stationary source during air pollution episodes are provided in Minn. R. Ch. 7009.1000 through 7009.1110.

We assert that the above statutory and regulatory authorities fulfill the requirements of Section 110(a)(2)(G).

Section 110(a)(2)(H): Future SIP revisions

The MPCA has submitted many updates to the SIP at 40 CFR § 52.1220 in the last several years, in addition to iSIPs when required by the Clean Air Act. We intend to continue to submit updates, as needed, in order to ensure changes at existing facilities will not jeopardize the NAAQS, to comply with new or revised NAAQS, or as requested by EPA (e.g., during a "SIP call"). Language confirming the MPCA's ability to adopt or rescind rules and standards related to air pollution can be found in Minn. Stat. § 116.07, subd. 4.

MPCA's authority to issue permits to regulate air pollution can be found in Minn. Stat. § 116.07, subd. 4a.

We assert that the above statutory authority fulfills the requirements of Section 110(a)(2)(H).

Section 110(a)(2)(I): Plan revisions for nonattainment areas

Per EPA's interpretation of the CAA and direction provided in the 2013 iSIP guidance document[3], states are not required to address this Section, as SIP submissions for specific nonattainment areas, as required under the CAA Title I, part D, are subject to a different submission schedule. The MPCA, is not, therefore, addressing Section 110(a)(2)(I) as a part of this iSIP.

Section 110(a)(2)(J): Consultation with government officials, public notification, and PSD and visibility protection

Consultation with government officials

Historically, MPCA actively participated in the Central Regional Air Planning Association, as well as the Central States Air Resource Agencies. MPCA is now a full-time member of the Lake Michigan Air Director's Consortium (LADCO), and has demonstrated that it frequently consults and discusses air quality issues with pertinent Tribes. In addition to LADCO, MPCA is an active participant in the National Association of Clean Air Agencies (NACAA), which has a member total of 185 air agencies, including representatives from all EPA regional offices and headquarters, across the United States.

Public notification

Minnesota dedicates portions of the MPCA website to enhancing public awareness of measures that can be taken to prevent exceedance of all NAAQS generally. Information for non-point (neighborhood), vehicle, and traditionally permitted sources can be found on MPCA's website, at https://www.pca.state.mn.us/air/sources-air-pollution. Information regarding the health impacts of air pollution, especially particulate matter and ozone, can be found at https://www.pca.state.mn.us/air/air-quality-and-health; current air quality and air quality forecasting for the entire state of Minnesota, new in 2017, is also available, at https://www.pca.state.mn.us/air/current-air-quality. MPCA staff developed a free mobile app that provides the same forecasting information as the website, but in a more mobile-friendly format; the app, Minnesota Air, is available for both iOS (Apple) and Android platforms, and can be download through the iOS App Store or Android's Google Play.

Minnesota's procedural rules, applicable across all MPCA media programs, are established in Minn. R. Ch. 7000; these rules include general guidelines, as well as information about contested case hearings (7000.1750 through 7000.2200), emergency and variance procedures (7000.5000 and 7000.7000), and ethical conduct and standards (7000.9000 and 7000.9100).

[3] Memorandum dated September 13, 2013, "Guidance on Infrastructure State Implementation Plan (SIP) Elements under Clean Air Act Sections 110(a)(1) and 110(a)(2)".

Minn. R. Ch. 7007.0850 lists public notice and comment procedures for the issuance of air quality permits. The public may petition for meetings and hearings, including for a contested case hearing, as it relates to any air permit (with reference back to Minn. R. Ch. 7000.1800). In addition to public notice of each air permit being issued by the MPCA, each SIP revision is put on notice, and the public is provided the opportunity to comment and/or request public hearings regarding proposed SIP revisions. This includes iSIPs, any SIP updates at 40 CFR § 52.1220, and site-specific SIP conditions incorporated into air permits at individual facilities (under title I and title 5).

Minn. R. Ch. 7007.0900 also provides for the review of part 70 permits by affected states. Specifically, "[t]he agency shall give notice of each draft part 70 permit, or major amendment to a part 70 permit, to any affected state on or before the time that the agency provides this notice to the public as required by part 7007.0850."

PSD and visibility protection

As described previously in greater detail, Minnesota's PSD program was recently approved by EPA and has been incorporated into the SIP at 40 CFR § 52.1220.

MPCA works with Federal Land Managers on a regular basis to discuss issues impacting Minnesota's Class I areas, including the U.S. Forest Service and the National Park Service.

MPCA is not, however, addressing visibility protection any further in this portion of the iSIP, per EPA's 2013 SIP guidance. The guidance states, on p. 55, that "[t]he EPA believes that there are no new visibility protection requirements under part C [of CAA title I, which is implemented through 40 CFR part 51 subp. P] as a result of a revised NAAQS. Therefore, there are no newly applicable visibility protection obligations pursuant to Element J after the promulgation of a new or revised NAAQS. Air agencies do not need to address the visibility subelement of Element J in an infrastructure SIP submission."

Summary

We assert that the above regulatory authority fulfills the requirements of Section 110(a)(2)(J).

Section 110(a)(2)(K): Air quality modeling and submission of modeling data

MPCA reviews the potential impact of major and some minor new sources.

Under Minn. R. Ch. 7007.0500, MPCA may require applicable major sources to perform modeling in order to demonstrate that emissions do not cause or contribute to a violation of any NAAQS. Minn. R. Ch. 7007.0500, subp. 1E, states that MPCA may notify an applicant that they are required to demonstrate that their emissions do not cause a violation of ambient air quality standards. Such information is mandatory for applicants subject to PSD requirements (Minn. R. Ch. 7007.3000) and/or NNSR requirements (Minn. R. Ch. 7007.4000 through 7007.4030).

The MPCA routinely requests and requires emissions information from air permit applicants. MPCA also maintains expert staff that conduct permit-related (and other) modeling, to support facilities and ensure modeling accuracy, as needed. More information on the MCPA's air modeling program can be found at https://www.pca.state.mn.us/air/air-quality-modeling.

Section 110(a)(2)(L): Permitting fees

The MPCA implements and operates Minnesota's Title V permit program, which EPA approved in full on December 4, 2001 (66 FR 62967). Included in our permit program are Minn. R. Ch. 7002.0005 through 7002.0085, Air Emission Permit Fees, which contain the provisions, requirements, and procedural structures associated with the costs for reviewing, approving, implementing, and enforcing various types of air permits.

We assert that the above regulatory authority, in addition to the approved Title V permit program, fulfills the requirements of Section 110(a)(2)(L).

Section 110(a)(2)(M): Consultation and participation by affected local entities

The MPCA develops, implements, and enforces Minnesota's air quality program and, in doing so, regularly consults with local political subdivisions affected by the SIP.

Under Minn. Stat. § 116.05, other departments and agencies are directed to cooperate with the MPCA, and the MPCA is granted the authority to work with those agencies.

Specifically, Minn. Stat. § 116.05, subd. 1, states that MPCA is "…authorized to cooperate and to enter into necessary agreements with other departments and agencies of the state, with municipalities, with other states, with the federal government and its agencies and instrumentalities in the public interest and in order to control pollution…"

The Minnesota Administrative Procedures Act (Minn. Stat. Ch. 14) provides general notice and comment procedures that govern rulemaking for all state agencies, which the MPCA follows during SIP development. For example, all SIP revisions are put on public notice in the state register; in doing so, the public is provided the opportunity to request a public meeting or comment on the SIP document. If a public meeting is requested, the MPCA will hold one.

We assert that the above statutory and regulatory authorities fulfill the requirements of Section 110(a)(2)(M).

Section 128: State board requirements [as related to Section 110(a)(2)(E)(ii)]

Section 128(a) of the CAA has two requirements:

> (1) that any board or body which approves permits or enforcement orders under this chapter shall have a majority of members who represent the public interest and do not derive any significant portion of their income from persons subject to permits and enforcement orders under this chapter, and
> (2) that any potential conflicts of interest by members of such board or body or the head of an executive agency with similar powers be adequately disclosed. Section 110(a)(2)(E)(ii) requires that states demonstrate compliance with section 128 as part of their Infrastructure SIP (see above).

Per statutory changes from the 2015 legislative session, the state of Minnesota no longer has any board or body which approves permits or enforcement orders in relation to the CAA. We do, however, have rules and statutes which address any potential conflicts of interest by the head of executive agencies that are applicable under the CAA.

The MPCA submitted the following statutes and rules to EPA on May 26, 2016, in addition to the Section 110(a)(2)(D) provisions for the 2008 ozone NAAQS. Per 82 FR 50807, published November 2, 2017, Minnesota's state board requirements – including the elements below – were approved for our previous multi-pollutant iSIP (effective December 4, 2017).

Section 128(a)(1)

Minnesota has no board or body which approves permits or enforcement orders in relation to the CAA. Instead, Minn. Stat. § 116.02, subd. 5, and Minn. Stat. § 116.03, subd. 1 provide the MPCA's Commissioner with the authority, powers, and duties to make decisions on behalf of the agency.

Section 128(a)(2)

Minnesota's statutes and rules require disclosure of any potential conflict of interest by public officials. Under Minn. Stat. Ch. 10A, matters of disclosure and public interest are governed by the Minnesota Campaign Finance and Public Disclosure Board (Board). Additional information about how the board makes decisions regarding disclosure is available at https://cfb.mn.gov/citizen-resources/board-programs/overview/government-officials-disclosure/. The Board's Public and Local Officials Handbook is available at https://cfb.mn.gov/pdf/publications/handbooks/Public_officials_handbook.pdf?t=1527106838 (updated 05/16/2018).

Minn. Stat. §10A.07 requires that, if the Commissioner has a financial interest relating to a matter before the agency, they must make this interest known, in writing. The decision-making responsibility regarding the matter must be either assigned by the Governor to another employee, or the Commissioner must abstain from influence over the matter in a manner prescribed by the Board.

Minn. Stat. § 10A.09 requires that statements of economic interest be filed with the Board upon the nomination of the Commissioner, and a supplementary statement must be submitted annually thereafter.

Minn. R. Ch. 7000.0300 further clarifies the need for candor and disclosure by the Commissioner, stating that:

> "In all formal or informal negotiations, communications, proceedings, and other dealings between any person and any member, employee, or agent of the board or commissioner, it shall be the duty of each person and each member, employee, or agent of the board or commissioner to act in good faith and with complete truthfulness, accuracy, disclosure, and candor."

Minn. Stat. § 10A.07, Minn. Stat. § 10A.09, and Minn. R. Ch. 7000.0300 were incorporated into Minnesota's SIP at § 52.1220 per 82 FR 50807.

Summary

Minnesota has no board governing activities related to the CAA. Our statutes and rules address any foreseeable issues of conflict, disclosure, and the public interest as they relate to the MPCA's commissioner. We therefore assert that the above statutory and regulatory authorities fulfill the requirements of Section 128, as it relates to 110(a)(2)(E)(ii).

Conclusions

Based on the information provided in the 2013 iSIP guidance, the 2018 Memo (and associated data updates), and previous iSIP submissions, the MPCA feels confident that the rules and statutes in place in Minnesota are more than sufficient to support our state's ambient air quality program, and to demonstrate that Minnesota is able to meet and comply with the 2015 ozone NAAQS.

Thus, all Section 110(a) iSIP requirements for the 2015 ozone NAAQS, including the interstate transport requirements, are met for the state of Minnesota.

Executive Summary

1 Introduction

The Lake Michigan Air Directors Consortium (LADCO) was established by the states of Illinois, Indiana, Michigan, and Wisconsin in 1989. The four states and EPA signed a Memorandum of Agreement (MOA) that initiated the Lake Michigan Ozone Study and identified LADCO as the organization to oversee the study. Additional MOAs were signed by the states in 1991 (to establish the Lake Michigan Ozone Control Program), January 2000 (to broaden LADCO's responsibilities), and June 2004 (to update LADCO's mission and reaffirm the commitment to regional planning). In March 2004, Ohio joined LADCO. Minnesota joined the Consortium in 2012. LADCO consists of a Board of Directors (i.e., the State Air Directors), a technical staff, and various workgroups. The main purposes of LADCO are to provide technical assessments for and assistance to its member states, and to provide a forum for its member states to discuss regional air quality issues.

1.1 Project Overview

LADCO conducted regional air quality modeling to support the statutory obligations of the LADCO states under Clean Air Section 110(a)(2)(D)(i)(i), which requires states to submit "Good Neighbor" state implementation plans (SIPs). These SIP revisions are plans to prohibit emissions in one state from interfering with the attainment or maintenance of the National Ambient Air Quality Standards (NAAQS) in another state. LADCO used the Comprehensive Air Quality Model with Extensions (CAMx) to support these analyses. The CAMx Anthropogenic Precursor Culpability Assessment (APCA) tool was used to assess the impacts of interstate transport of air pollution on ground level ozone (O_3) concentrations in the Midwest and Northeast U.S.

In support of previous rulemakings (CSAPR, 2011; CSAPR Update, 2016), the U.S. EPA in partnership with states developed a four-step interstate transport framework to address the "Good Neighbor" provisions of the O_3 and $PM_{2.5}$ NAAQS. This framework established the following four steps to identify and mitigate high O_3 concentrations at locations that were at risk of violating the NAAQS in the future: (1) identify monitors with predicted air quality problems in the future year, (2) identify the upwind states that are "linked" through air mass transport to the problem monitors, (3) identify emissions reductions necessary to prevent upwind states from contributing significantly to NAAQS violations at a downwind monitor, and (4) adopt permanent and enforceable measures needed to achieve the identified emissions reductions. Recently, EPA (2018) issued a memo describing a series of potential flexibilities in this four step framework that states could consider in developing a transport SIP.

LADCO used CAMx to predict O_3 concentration in 2023 to address steps (1) and (2) of the four-step interstate transport framework. The LADCO CAMx modeling results are used here to identify O_3 monitoring sites that may have nonattainment or maintenance problems for the 2015 O_3 NAAQS in 2023. The modeling outputs are also used to quantify the contributions of emissions in upwind states to the monitors in downwind states that are projected to have NAAQS attainment problems in 2023. LADCO presents several "flexibilities" in the analytic approaches used to quantify transport and state linkages per a March 2018 U.S. EPA (2018) memo. These alternatives include a comparison between EPA and LADCO CAMx modeling for 2023, exploring the impacts of including or removing water cells in future design values, and exploring the influence of model bias on future design values. All of the alterative analyses presented here are in the context of establishing links between an upwind state and downwind nonattainment or maintenance problems at surface O_3 monitors in the Midwest and Northeast U.S.

This document describes how LADCO used CAMx source apportionment modeling to link upwind and downwind states and to identify upwind emissions sources that significantly contribute to downwind NAAQS attainment issues. The CAMx APCA modeling outputs of this work are being presented to the LADCO states to support the "Good Neighbor" SIP provisions of their 2015 O_3 NAAQS Infrastructure SIPs (iSIP) that are due to EPA in October 2018.

1.2 Organization of the Technical Support Document

This technical support document (TSD) is presented to the LADCO states for estimating year 2023 O_3 design values and source-receptor relationships using the CAMx APCA technique. The TSD is organized into the following sections. Section 0 describes the 2023 Air Quality Modeling Platform that LADCO used to forecast 2023 O_3. Section 0 describes the approach used for estimating Future Ozone Design Values. This section also includes a discussion on the methods used for identifying sites that are forecast to have O_3 NAAQS attainment problems. Section 0 describes the Ozone Source Apportionment modeling used to link source regions with problem monitors in the future year. Section 0 presents the modeling results that the LADCO states can use to support their 2015 O_3 NAAQS Good Neighbor SIPs. This section includes the following results:

- LADCO benchmarking of the EPA modeling platform on the LADCO computing system;
- Future year air quality forecasts from the LADCO CAMx modeling;
- Interstate transport linkages estimated with the LADCO forecasts;
- Alternative attainment test results of future year design values computed with different analysis flexibilities

2 2023 Air Quality Modeling Platform

LADCO based our 2023 O_3 air quality and interstate transport forecasts on the CAMx modeling platform released by the U.S. EPA in October 2017 in support of the Interstate Transport SIPs for the 2008 O_3 NAAQS (US EPA, 2017). The EPA 2023EN modeling platform was projected from a 2011 base year and included a complete set of CAMx inputs, including meteorology, initial and boundary conditions, and emissions data. The future year, or 2023, component of the air quality modeling platform refers to the emissions data only. All other CAMx inputs, including the meteorology data simulated with the Weather Research Forecast (WRF) model, represented year 2011 conditions. LADCO used the majority of the data and software provided by EPA for this platform, with a few exceptions described below.

2.1 Modeling Year Justification

LADCO selected 2011 as a modeling year for this study because CAMx input data for 2011 were widely available and relatively well-evaluated. 2011 had also been identified as a good year for studying O_3 in the Eastern U.S. The US EPA (2015) noted that year 2011 meteorology in the Eastern U.S., including the LADCO region, was warmer and drier than the climatic norm. As compared to other recent years, the summer of 2011 represented typical conditions conducive to high observed O_3 concentrations in the Midwest and Northeast U.S.

Figure 1 shows the 2009-2013 base year O_3 design values for the modeling period selected for this study. Each bubble on the plot represents an Air Quality System (AQS) O_3 surface monitor. Orange, red, and purple colors indicate monitors that were nonattainment (>=71.0 ppbV) for the 2015 O_3 NAAQS during this period. High O_3 concentrations were observed throughout the domain, with particularly high values along the Lake Michigan shoreline, St. Louis, southern Indiana, and the Northeast Corridor from Washington D.C. to Connecticut.

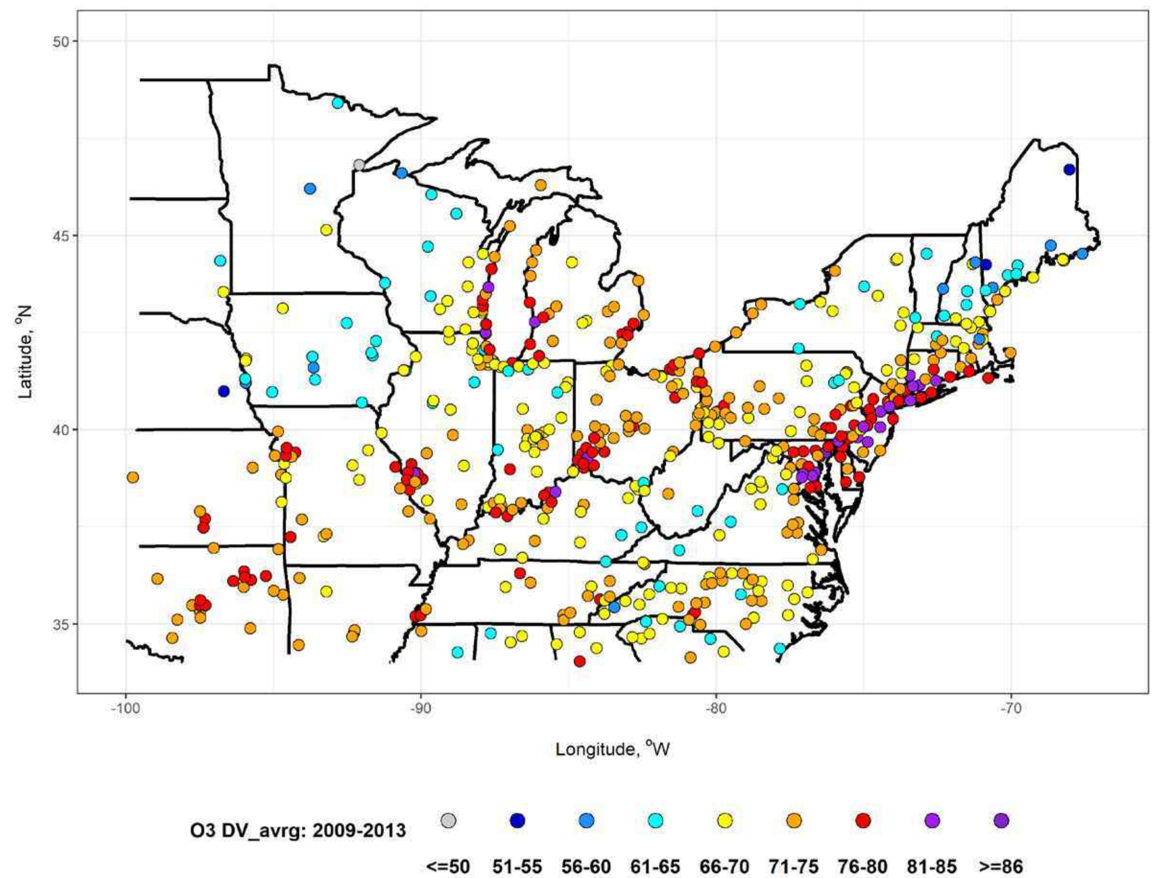

Figure 1. 2011 (2009-2013) O_3 design values for the eastern U.S.

The triennial National Emissions Inventory (NEI) also synchronized with 2011. Since its first release in 2014, the NEI2011 has undergone several revisions, with the most recent updates to version 6.3 released in October 2017 as part of the U.S. EPA's final 2008 O_3 NAAQS interstate transport assessment (US EPA, 2017). The 2011-based emissions modeling platforms are currently the best available national-scale datasets for simulating air quality in the U.S. The U.S. EPA used version 6.3 of the NEI2011-based emissions modeling platform for their preliminary assessment of O_3 transport for the 2015 O_3 NAAQS (US EPA, 2016). Given recent use of 2011-based data for evaluating interstate transport by the U.S. EPA and the lack of a more contemporary national emissions modeling platform, LADCO believes that using 2011-based data and emissions projections are justified for assessing interstate O_3 transport.

LADCO selected 2023 as the future project year based on the availability of data from EPA. EPA selected 2023 for 2015 O_3 NAAQS modeling because it "aligns with the anticipated attainment year for moderate O_3 nonattainment areas" (US EPA, 2018).

2.2 Air Quality Model Configuration

LADCO based the CAMx air quality modeling platform for this study on the configuration that the U.S. EPA used to support both their October 2017 memo on

Interstate Transport SIPs for the 2008 O_3 NAAQS (US EPA, 2015) and their December 2016 technical support document on a preliminary assessment of Interstate Transport for the 2015 O_3 NAAQS (US EPA, 2016). LADCO used CAMx v6.40 (Ramboll-Environ, 2016) as the photochemical grid model (PGM) for this study. CAMx is a three-dimensional, Eulerian air quality model that simulates the chemical transformation and physical transport processes of air pollutants in the troposphere. It includes capabilities to estimate the concentrations of primary and secondary gas and particle phase air pollutants, and dry and wet deposition, from urban to continental spatial scales. As CAMx associates source-level air pollution emissions estimates with air pollution concentrations, it can be used to design and assess emissions reduction strategies pursuant to NAAQS attainment goals.

LADCO selected CAMx for this study because it is a component of recent U.S. EPA modeling platforms for investigating the influence of interstate transport on O_3, and because it has source apportionment capabilities for quantifying air pollution source-receptor relationships. As CAMx is a component of U.S. EPA studies with a similar scope to this project, LADCO was able to leverage the data and software elements that are distributed with U.S. EPA regulatory modeling platforms. Using these elements saved LADCO significant resources relative to building a modeling platform from scratch. CAMx is also instrumented with source apportionment capabilities that allowed LADCO to investigate the sources of air pollution impacting O_3 monitors within and downwind of the LADCO region.

Figure 2 shows the U.S. EPA transport modeling domain for the continental U.S. A 12-km uniform grid (CONUS12) covers all of the continental U.S. and includes parts of Southern Canada and Northern Mexico. The domain has 25 vertical layers with a model top at about 17,550 meters (50 mb). LADCO used the same U.S. EPA 12-km domain for this project because it supported the use of meteorology, initial and boundary conditions, and emissions data that were freely available from U.S. EPA.

As the focus of this study is on O_3, LADCO used CAMx to simulate the O_3 season. LADCO simulated May through September 2011 as individual months using 10-day model spin-up periods for each month.

Complete details of the EPA 2011 CAMx simulation, including a performance evaluation of the model are available from the U.S. EPA (2016).

Figure 2. CAMx 12-km modeling domain (CONUS12)

2.3 Meteorology Data

LADCO used the U.S. EPA 2011 WRF data for this study (US EPA, 2017). The U.S. EPA used version 3.4 of the WRF model, initialized with the 12-km North American Model (NAM) from the National Climatic Data Center (NCDC) to simulate 2011 meteorology. Complete details of the WRF simulation, including the input data, physics options, and four-dimensional data assimilation (FDDA) configuration are detailed the EPA 2008 Transport Modeling technical support document (US EPA, 2015). U.S. EPA prepared the WRF data for input to CAMx with version 4.3 of the WRFCAMx software.

2.4 Initial and Boundary Conditions

LADCO used 2011 initial and boundary conditions for CAMx generated by the U.S. EPA from the GEOS-Chem Global Chemical Transport Model (US EPA, 2017). EPA generated hourly, one-way nested boundary conditions (i.e., global-scale to regional-scale) from a 2011 2.0 degree x 2.5 degree GEOS-Chem simulation. Following the convention of the U.S. EPA O_3 transport modeling, year 2011 GEOS-Chem boundary conditions were used by LADCO for modeling 2023 air quality with CAMx.

2.5 Emissions Data

The 2023 emissions data for this study were based on the U.S. EPA 2011v6.3 ("EN") emissions modeling platform (US EPA, 2017b). US EPA generated this platform for their final assessment of Interstate Transport for the 2008 O_3 NAAQS. Updates from earlier 2011-based emissions modeling platforms included a new engineering approach for forecasting emissions from Electricity Generating Units (EGUs). The U.S. EPA made several changes to the base 2011 and forecasted 2023 emissions in the "EN" platform relative to the earlier "EL" platform (US EPA, 2017b).

LADCO replaced the EGU emissions in the EN platform with 2023 EGU forecasts estimated with the ERTAC EGU Tool version 2.7[1]. The ERTAC EGU Tool provided more accurate estimates of the growth and control forecasts for EGUs in the Midwest and Northeast states than the EPA approach used for the "EN" platform. LADCO used the EPA EN Platform emissions estimates for all other inventory sectors.

2.5.1 Electricity Generating Unit Emissions

The ERTAC EGU model for growth was developed around an activity pattern matching algorithm deliberately built to provide hourly EGU emissions data for air quality planning. The original goal of the model was to create low cost software that air quality planning agencies could use for developing EGU emissions projections. States needed a transparent model that was numerically stable and did not change dramatically with small changes in inputs. A key feature of the model includes data transparency, where all inputs are publicly available. The code is also operationally transparent, which includes extensive documentation, open source code, and a diverse user community to support new users of the software.

Operation of the model is straightforward given the complexity of the projection calculations and inputs. The model imports base year Continuous Emissions Monitoring data from US EPA and sorts the data from peak to the lowest generation hour. It applies hour specific growth rates that include peak and off peak rates. The model then balances the system for all units and hours that exceed physical or regulatory limits. Finally, future year controls are applied to the emissions estimates and tests for reserve capacity, final reporting, and conversion to a SMOKE ready modeling files is done.

ERTAC EGU has distinct advantages over other growth methodologies because it is capable of generating hourly future year estimates which are key to understanding O_3 episodes. Additionally it does not shutdown or mothball existing units because economics algorithms suggest they are not economically viable. Additionally, alternate control scenarios are easy to simulate with the model. Full documentation for the ERTAC Emissions model and 2.7 simulations are available through the MARAMA website[1].

2.5.2 LADCO 2023 Emissions Summary

The tables and figures in this section summarize the emissions used in the LADCO and EPA 2023 CAMx simulations. Table 1 shows the annual NOx and SO_2 EGU emissions for the base year (2011), ERTAC EGU 2023, and the EPA EN 2023 inventories. LADCO state and regional total emissions are presented in this table. Figure 3 and Figure 4 summarize the NOx and SO_2 emissions graphically for the LADCO states. The ERTAC EGU 2023 and EPA EN 2023 EGU emissions estimates differ across the LADCO states. ERTAC estimates 3,314 tons/year more NOx and 8,152 tons/year more SO_2 for IL EGUs than the EPA EN projections. ERTAC estimates 12,567 tons/year more NOx and 24,356

[1] http://www.marama.org/2013-ertac-egu-forecasting-tool-documentation

tons/year more SO_2 in OH than the EPA EN projections. The MI EGU projections are lower from ERTAC by 5,731 tons/year NOx and 23,434 tons/year SO_2 than the EPA EN projections. The differences for IN EGUs are mixed with ERTAC projecting 2,083 tons/year less NOx and 34,393 tons/year more SO_2 than the EPA EN projections.

Regionally, ERTAC projects lower NOx but higher SO_2 emissions in the Northeast and Southeast relative to the EPA EN projections. ERTAC EGU projects higher NOx and SO_2 emissions across the CENSARA and WESTAR states relative to the EPA 2023 projections.

While these annual summaries mask the fine scale temporal differences between the EGU projection methodologies, in general the differences in O_3 projections between the LADCO and EPA simulations (Section 5.4.1,) are consistent with the differences in annual total NOx emissions between the EGU projections used in each simulation. The LADCO 2023 simulation generally forecasted lower O_3 in the Northeast and Southeast than the EPA 2023 EN simulation, consistent with the lower EGU NOx emissions predicted by ERTAC EGU in these regions.

2.6 U.S. EPA Modeling Platform Benchmarking

LADCO benchmarked both the U.S. EPA 2011 and 2023 CAMx "EN" modeling platforms on our computing cluster. The benchmark simulation used the exact same CAMx version and configuration as was used by U.S. EPA. The purpose of these simulations was to confirm that LADCO correctly installed and configured the EPA data and software on our cluster. We needed to verify our installation of the modeling platform on the LADCO computing cluster in order to take advantage of the extensive vetting and evaluation of the platform by U.S. EPA. By reproducing the U.S. EPA CAMx modeling results on the LADCO computer, we inherited the model evaluation completed by the U.S. EPA, thereby validating the use of the platform for this study.

LADCO verified the platform installation on our computing systems by comparing the results of the U.S. EPA and LADCO 2011 and 2023 EN simulations. We simulated the entire O_3 season, with spin up, for both 2011 and 2023 for comparison with the U.S. EPA modeling. The LADCO benchmarking results for the 2011 simulation are presented in Section 5.1.

2.7 Evaluation of the LADCO 2023 CAMx Simulation

As future year air quality forecasts cannot be compared to observations for evaluation, LADCO relied on the model performance evaluation (MPE) conducted by the U.S. EPA on the base modeling platform that we used for this study (US EPA, 2016). In addition to the MPE for the base year CAMx simulation, the U.S. EPA reported full MPE results for the 2011 WRF modeling (US EPA, 2014) used to drive the CAMx simulations.

LADCO compared the 2023 O_3 forecasts that we generated in this study against the 2023 U.S. EPA "EN" platform results. We compared daily average and daily maximum 1-

hour and 8-hour O_3 concentrations at monitoring locations in the Midwest and Northeast. The purpose of this comparison was to evaluate the changes in the LADCO forecasts that result from the change in the EGU emissions forecasts used for this study relative to the U.S. EPA 2023 modeling. The comparisons of the 2023 O_3 forecasts for the LADCO and EPA CAMx simulations are presented in Section 5.2.

3 Future Year Ozone Design Values

LADCO followed the U.S. EPA Draft Guidance for Attainment Demonstration Modeling (US EPA, 2014b), herein referred to as the U.S. EPA Guidance, to calculate future year design values (DVFs) for monitors in the Midwest and Northeast U.S. As we used a base year of 2011, we estimated the base year design values (DVCs) using surface observations for the years 2009-2013. LADCO estimated the DVFs with version 1.2 of the Software for Modeled Attainment Test Community Edition (SMAT-CE)[2]. SMAT-CE was configured to use the average O_3 concentration in a 3x3 matrix around each monitor across the 10 highest modeled days, per the U.S. EPA Guidance.

SMAT-CE uses a four step process to estimate DVFs:

1. Calculate DVC for each monitor
   - For O_3, the design values is a three-year average of the 4th highest daily maximum 8 hour average O_3 ($MDA8_4$):

$$DV_{2011} = (MDA8_{4,2009} + MDA8_{4,2010} + MDA8_{4,2011})/3$$

   - Weighted 5-year average of design values centered on the base model year (2011):

$$DVC_{2011} = (DV_{2011} + DV_{2012} + DV_{2013})/3$$

2. Find top 10 base year modeled days surrounding each monitor
   - Find ten days with the highest base year modeled MDA8 from within a 3x3 matrix of grid cells surrounding each monitor
   - Only days with modeled MDA8 >= 60 ppb are used
3. Calculate relative response factor (RRF) for each monitor
   - Calculate averaged MDA8 for the base and future years from the average of the values in the 3x3 matrix in each of the selected top 10 modeled days
   - Calculate the RRF as the ratio of the future to base year averaged MDA8:

$$RRF = MDA8_{2023,avg}/MDA8_{2011,avg}$$

4. Calculate DVF for each monitor

$$DVF = RRF * DVC_{2011}$$

Following from the U.S. EPA March 2018 Ozone Transport Memo, we also calculated DVFs to account for the influence of surface water on CAMx performance over coastal regions. The alternative DVF calculation approach presented by EPA excludes from the 3x3 matrix around a monitor those model grid cells that are dominated by water (> 50% water by landuse coverage). In the case of water-dominated grid cells that include a monitor, the monitor cell is included in the alternative calculation.

[2] https://www.epa.gov/scram/photochemical-modeling-tools

Additional details of the EPA approaches that LADCO used for calculating DVFs are provided in the U.S. EPA's Ozone Transport Modeling Assessments (US EPA 2018; US EPA, 2016; US EPA, 2015).

LADCO employed another alternative for calculating DVFs that considers the skill of CAMx in reproducing the base year observations near a monitor. The standard EPA DVF approach uses the ten modeled days with the highest MDA8 concentrations around a monitoring location to estimate the relative response factor (RRF) for a monitor. In this approach, the top ten days are selected irrespective of the ability of the model to reproduce the observations during the selected days. Table 3 illustrates an example of the MDA8 modeled and observed concentrations at the Chiwaukee Prairie, WI monitor on the top 10 modeled days from the LADCO 2011 CAMx simulation. The table shows that 6 of the top 10 modeled days correspond with days that are in the top 10 observed days (yellow shading); two of the top 10 modeled days are in the top 15-20 observed days (orange shading). Four of the top 10 modeled days also have percent biases greater than 15%, with one day exhibiting a model overprediction of greater than 134%.

Table 3. Chiwaukee Prairie, WI (AQS ID: 550590019) top 10 modeled MDA8 days

Date	OBS*	MOD*	BIAS*	BIAS%
7/4/2011	79.25	105.63	26.38	33.29%
7/9/2011	83.00	101.03	18.03	21.72%
7/24/2011	41.63	97.69	56.06	134.69%
7/30/2011	51.75	91.22	39.47	76.26%
9/1/2011	96.00	91.21	-4.79	4.99%
7/17/2011	88.25	82.95	-5.30	6.01%
7/10/2011	77.38	78.89	1.52	1.96%
7/23/2011	74.88	77.36	2.49	3.32%
6/7/2011	68.38	73.93	5.55	8.12%
9/2/2011	71.13	73.75	2.62	3.69%

*Units = ppbV

The alternative DFV calculation explored by LADCO filtered the model results by bias, selecting the top 10 model days only from days when the bias falls below a certain threshold. As the EPA Modeling Guidance (2014b) sets the model performance goal for O_3 at 15% mean bias, LADCO excluded days with a bias greater than 15% in an alternative "bias filtered" DVF calculation. Table 4 extends the example for the Chiwaukee Prairie, WI monitor by showing the top 10 modeled days with absolute modeled bias less than 15%. Filtering out the high bias days results in all of the top 10 modeled days corresponding to days in which the observations were in the top 20 concentrations of all days. With this approach, not only will more of the highest concentration observed days be included in the RRF calculation but the days that are included will be those in which the model was able to better reproduce the observations. In exhibiting better skill on these days, the model has a better chance of capturing the causes of the high O_3 and subsequently simulating the sensitivity of changes in emissions on the O_3 concentrations.

Table 4. Chiwaukee Prairie, WI top 10 modeled MDA days with bias <= 15%

Date	OBS	MOD	BIAS	BIAS%
9/1/2011	96.00	91.21	-4.79	4.99%
7/17/2011	88.25	82.95	-5.30	6.01%
7/10/2011	77.38	78.89	1.52	1.96%
7/23/2011	74.88	77.36	2.49	3.32%
6/7/2011	68.38	73.93	5.55	8.12%
9/2/2011	71.13	73.75	2.62	3.69%
8/31/2011	70.38	72.49	2.12	3.01%
6/6/2011	75.29	71.73	-3.56	4.73%
8/2/2011	75.50	69.47	-6.03	7.98%
7/15/2011	65.75	67.48	1.73	2.63%

*Units = ppbV

The DVFs at nonattainment and maintenance monitors in the Midwest and Northeast U.S. from the three alternative comparisons: EPA vs LADCO, LADCO water vs no water, and LADCO bias filtered are presented in Section 0.

LADCO used the DVFs to identify nonattainment and maintenance sites in 2023 using the most recent 3-year monitored design values (2015-2017) per the CSAPR Update methodology (CSAPR Update, 2016). Under this methodology sites with average DVFs that exceed the 2015 NAAQS (71 ppb or greater) and that are currently measuring nonattainment would be considered nonattainment receptors in 2023. Further, monitoring sites with maximum DVFs that exceeds the NAAQS would be considered a maintenance receptor in 2023. Under the CSAPR Update, maintenance only receptors include both those sites where the average DVF is below the NAAQS, but the maximum DVF is above the NAAQS; and monitoring sites with average DVFs above the NAAQS but with DVCs that are below the NAAQS.

The sites that LADCO identified through this process as having potential for nonattainment and maintenance designations for the 2015 O_3 NAAQS in 2023 were the focus of our source apportionment analyses. LADCO used the CAMx source apportionment APCA technique to assess the impacts of upwind sources on nonattainment and maintenance monitors in downwind states. Section 5.3 presents the results of the linkages of LADCO states to downwind maintenance and nonattainment monitors using a threshold of 1% of the NAAQS (0.70 ppb).

4 Ozone Source Apportionment Modeling

LADCO used the CAMx Anthropogenic Precursor Culpability Assessment (APCA) tool to calculate emissions tracers for identifying upwind sources of O_3 at downwind monitoring sites. We selected the APCA technique because it more appropriately associates O_3 formation to anthropogenic sources than the CAMx Ozone Source Apportionment Technique (OSAT). If any anthropogenic emissions are involved in a reaction that leads to O_3 formation, even if the reaction occurs with biogenic VOC or NOx, APCA tags the O_3 as anthropogenic in origin.

In the LADCO 2023 CAMx Source Apportionment modeling protocol (LADCO, 2018), we presented a configuration to tag both source regions and emissions inventory sectors for our APCA modeling. In the final APCA configuration, we primarily tagged only source regions in order to better leverage both the EPA 2023 EN CAMx modeling platform and to optimize the simulation on the LADCO computing cluster. We consolidated the 54 source tracers used by EPA into 32 tracers (Figure 5) based on an analysis of the linkages in the EPA modeling results. We maintained explicit O_3 tracers for only those states that had CSAPR linkages (at least 0.7 ppb MDA8) to nonattainment and maintenance monitors in the latest EPA 2023 modeling (US EPA, 2018). For the rest of the states, such as New England, most of the Southeast, and the West, we grouped them into single tracers for computational efficiency. Following from the EPA 2023 EN modeling platform, in addition to each source region, LADCO created explicit tags for fire emissions, biogenic emissions, offshore emissions, tribal emissions, Canada/Mexico emissions, and Initial/Boundary Conditions.

LADCO used the EPA 2023 EN data processing methods for preparing emissions for the APCA simulation. EPA developed a technique to convert all of the emissions data, including non-point sources such as biogenics and onroad mobile, to CAMx point source formatted data. Tagging of the emissions by state FIPs code is done during the emissions processing sequence to ensure that all of the emissions are properly attributed to the state from which they originate. This tagging is done to avoid the conventional problem in source apportionment modeling of mismatches between grid cell-based source regions and actual political boundaries. Additional details of the EPA emissions tagging approach are in U.S. EPA (2016).

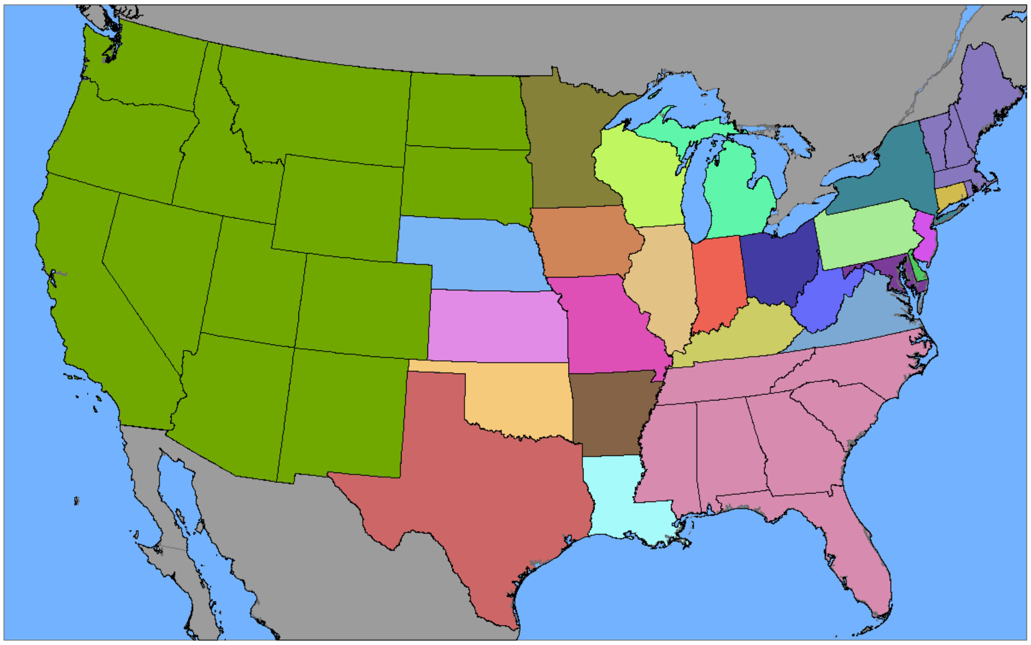

Figure 5. CAMx APCA Source Regions

We used the CAMx APCA results to calculate an O_3 contribution metric for each potential nonattainment and maintenance monitor in the Midwest and Northeast U.S. (US EPA, 2016). The contribution metric is designed to provide a reasonable representation of individual states and sources to the design values at downwind monitors in future years. In particular, per the CSAPR methodology, downwind monitors are considered to be linked to upwind sources if a modeled contribution assessment shows impacts at a monitor that equal or exceeds 1% of the NAAQS. For the 2015 O_3 NAAQS, source regions (and inventory sectors) that contribute 0.70 ppb or more to a monitor would be considered significant contributors to a nonattainment or maintenance monitor.

In Section 0 LADCO presents alternative design values and source apportionment modeling results for different transport modeling flexibilities. This section shows how the 2023 contributions and design values change with different EGU emissions, considerations of whether or not water cells are included in DVF calculations, and considerations of the model bias in the DVF calculations.

5 Results and Discussion

5.1 EPA 2011 EN Platform Benchmarking Results

LADCO simulated the entire O_3 season (May 1 – September 30, 2011) with CAMx using the EPA 2011 EN modeling platform. The purpose of the benchmarking simulation was to demonstrate that LADCO could closely reproduce the EPA results using the same model inputs and configuration used by EPA on a different computing infrastructure. By demonstrating that LADCO can reproduce the EPA results, we establish the validity of the EPA modeling platform on the LADCO systems and inherit the full model performance evaluation and vetting process used by EPA for the 2011 EN platform (US EPA, 2016).

Figure 6 and Figure 7 compare O_3 season MDA8 O_3 between the LADCO 2011 (LADCO_2011en) and the EPA 2011 EN simulations at the locations of all of the AQS and CASTNET monitors in the CONUS12 domain, respectively. The data for these figures are paired in space and time, meaning that each symbol on the plot represents a comparison of the two simulations at the same monitor on the same day. While there is some variability between the two runs (AQS maximum absolute MDA8 difference is 7.06 ppbV), the runs are not expected to be exactly the same due to numerical differences in computing architectures between the EPA and LADCO computing systems. For 194,953 AQS data pairs, the Pearson correlation coefficient for the LADCO and EPA simulations is 0.99969 and the coefficient of determination (R^2) is 0.999, indicating that the two simulations produced very similar results. The comparison of predicted O_3 concentrations at the rural CASTNET monitors shows similar correspondence between the runs ($R^2 = 0.999$).

Figure 8 shows a timeseries comparison of MDA8 O_3 for the EPA and LADCO 2011 simulations at a single monitor location. Each data point on this figure represents the daily MDA8 for the two simulations at the Chiwaukee Prairie monitor in southeastern Wisconsin. This figure also shows a very close correspondence between the EPA (blue line) and LADCO (red line) simulations relative to the observations (black line).

The close correspondence in predicted O_3 between the EPA and LADCO 2011 simulations illustrated in these figures is consistent across states, monitoring networks and time periods. These results demonstrate the LADCO was able to effectively port the EPA 2011 EN modeling platform to the LADCO computing cluster and use the platform as the basis for projecting future year O_3 concentrations. Despite the numerical differences introduced into the 2011 EN simulation by the LADCO computing architecture, LADCO will forecast 2023 O_3 on the same computing architecture as the 2011 benchmark simulation to ensure comparability between the LADCO 2011 and 2023 simulations.

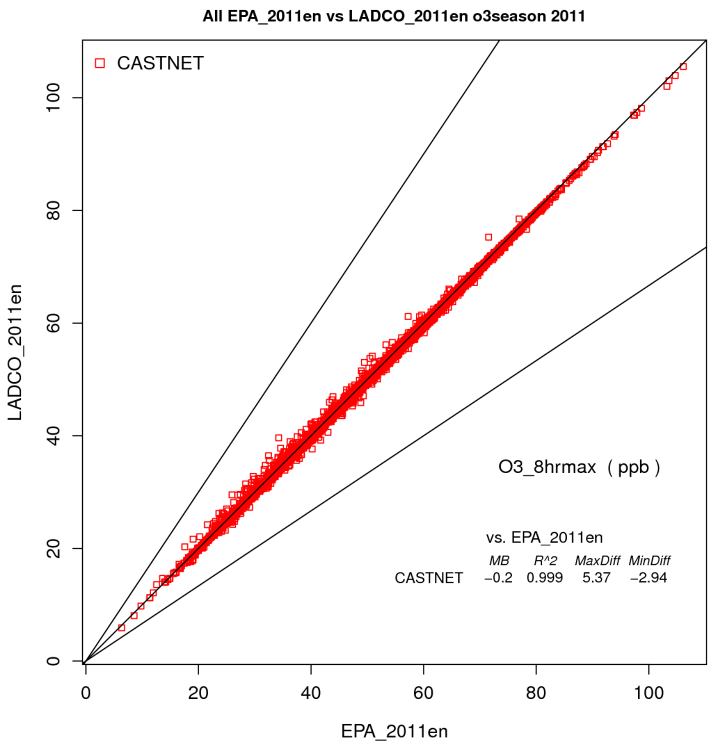

Figure 7. LADCO vs EPA 2011 EN summer season CASTNET MDA8 O_3

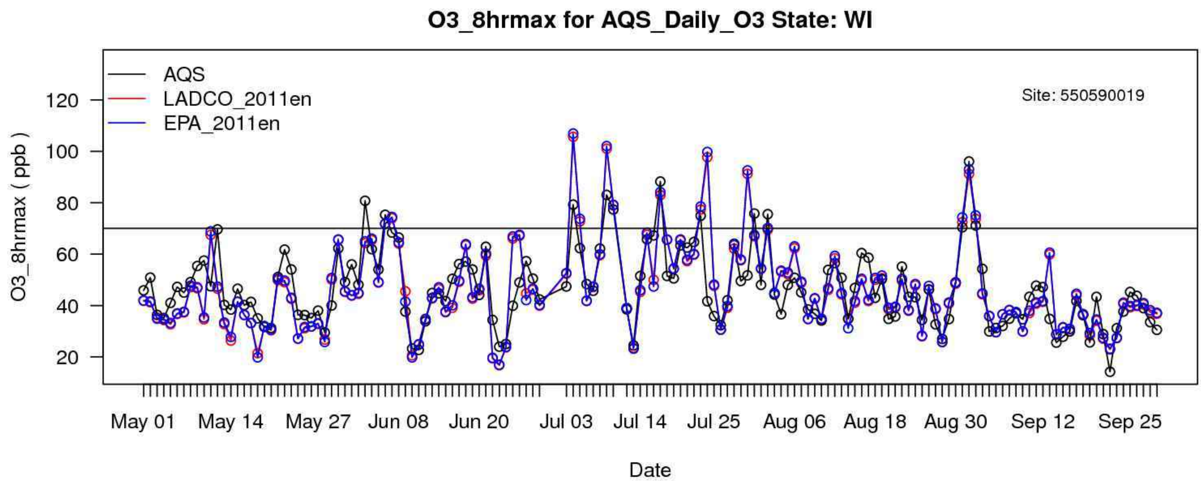

Figure 8. Timeseries of MDA8 O_3 at Chiwaukee Parairie, WI comparing EPA and LADCO 2011 simulations.

5.2 LADCO 2023 Air Quality Projections

LADCO modified the emissions in the EPA 2023 EN platform to create a LADCO 2023 modeling platform (see Section 2.5). The LADCO 2023 simulation forecasts air quality for the continental U.S. using the best available information for North American emissions, including EGU emissions forecasts from the ERTAC v2.7 model. Figure 9 shows the O_3 season (May through September) maximum of MDA8 O_3 for the LADCO and EPA 2023 CAMx simulations on the CONUS12 modeling domain. Figure 10 shows the difference in O_3 season maximum (LADCO – EPA) between the two simulations. Cool colors indicate that the EPA simulation forecasts higher O_3 than the LADCO simulation; warm colors indicate higher O_3 in the LADCO forecast. In general, the EPA simulation predicts higher O_3 in the Midwest, Northeast, Gulf Coast, and Pacific Coast states; the LADCO simulation predicts higher O_3 in the Four Corners region and Central Arkansas. Note that the trends shown in these figures mask finer temporal resolution features (i.e., hourly and daily) that also exist between the LADCO and EPA 2023 simulations.

Figure 11 and Figure 12 compare O_3 season MDA8 O_3 between the LADCO 2023 (LADCO_2023en) and the LADCO 2011 (LADCO_2011en) simulations at the locations of all of the AQS and CASTNET monitors in the CONUS12 domain, respectively. As both of these simulations were run on the LADCO computing cluster, the differences in the runs are due entirely to the emissions projections from 2011 to 2023. The LADCO simulation forecasts MDA8 O_3 to decrease in 2023 by an average of 5.34 ppbV across all AQS monitors and by an average of 6.13 ppbV across all CASTNET monitors. These changes are similar to the EPA forecasts, which estimated average decreases in MDA8 O_3 of 5.23 ppbV at the AQS monitors and 6.15 ppbV at the CASTNET monitors.

Figure 13 shows the O_3 DVFs and RRFs from the LADCO 2023 simulation. LADCO generated these results with SMAT-CE using the standard US EPA attainment test configuration (top 10 modeled days, 3x3 cell matrix around the monitor, including water cells). ***The LADCO 2023 CAMx simulation forecasts that no monitors in the Midwest or Northeast will be nonattainment (orange) for the 2015 O_3 NAAQS.*** The highest mean DVF in these regions is the Suffolk County, NY (AIRS ID: 36103002) monitor at 69.8 ppbV; the highest maximum DVF is Fairfield, CT (AIRS ID: 90019003) at 72.4 ppbV. The RRF plot indicates that the largest reductions (25-30%) in DVFs are forecasted to occur in Chicago, Louisville, Cincinnati, and North Carolina. Regionally, the Mid-Atlantic and Northeast are forecasted to experience widespread reductions in O_3 DVFs in the range of 20-25%.

Figure 14 shows the LADCO DVFs zoomed in on the Lake Michigan region. This plot highlights that only two Lake Michigan shoreline monitors, Sheboygan Co., WI and Allegan Co., MI are at or near maintenance of the 2015 O_3 NAAQS. A third monitor in Wayne Co., MI is also forecast to be near maintenance status.

Table 5 presents the average and maximum DVFs for the near nonattainment and maintenance monitors in the Midwest and Northeast. The red highlighted values indicate forecasted maintenance status for the 2015 O_3 NAAQS. The Kohler Andre monitor in Sheboygan, WI (AIRS ID: 551170006) is the only forecasted maintenance monitor in the LADCO region with a maximum DVF of 71.5 ppbV.

5.3 Interstate Transport Linkages

Table 6 shows the MDA8 O_3 DVF CSAPR linkages between states and monitors estimated by the LADCO 2023 simulation. These linkages are derived from the standard EPA attainment test that includes water cells in the 3x3 matrix surrounding each monitor. The linkages in Table 6 are provided for the same monitors highlighted in Table 5. While there are no projected nonattainment monitors in the LADCO 2023 simulation, the maintenance monitors are highlighted in red text. The states with contributions that equal or exceed 1% of the 2015 O_3 NAAQS (0.70 ppbV) are highlighted with yellow shading.

As described above, the only monitor in the LADCO region projected to be in maintenance for the 2015 O_3 NAAQS by the LADCO 2023 modeling is the Kohler Andre monitor in Sheboygan, WI with a maximum DVF of 71.5 ppbV. Illinois is the highest contributing source region linked to this monitor (14.13 ppbV) followed by WI (9.54 ppbV), IN (6.24 ppbV), MI (2.15 ppbV), and TX (2.02 ppbV). While all of the LADCO states, with the exception of MN, have CSAPR-significant linkages to the maintenance monitors in the Northeast, OH has the largest single contribution to a monitor outside of the LADCO region (2.88 ppbV at Harford, MD). Despite projected attainment, the Wayne Co., MI monitor experiences the largest influence from outside of the U.S. (CNMX = 3.22 ppbV) of all of the monitors in Table 6.

Figure 15 through Figure 23 show the 2023 ozone season maximum of the CAMx APCA O_3 tracers for the LADCO states, Texas, Offshore (commercial marine) sources, and Canada+Mexico. While these plots do not indicate the conditions in which these maximum values occur (i.e., on high or low O_3 days), they do show the maximum magnitudes and spatial extents of the influence of each state on regional O_3 concentrations. Figure 15 shows that CAMx estimated that IL contributes a domain maximum O_3 concentration of 70.8 ppbV. The maximum influence of IL emissions on O_3 is near Chicago and over Lake Michigan. Within the LADCO region, IL sources have the greatest influence on O_3 concentrations in southeast WI, northwest IN, and the Lower Peninsula of MI. CAMx estimated that IL contributes a maximum of 2-4 ppbV O_3 to the coastal areas in the Northeast and up to 8 ppbV O_3 as far south as the Louisiana Gulf Coast.

Figure 16 shows that CAMx estimated that IN contributes a domain maximum 46.6 ppbV O_3. The highest contributed O_3 concentrations from IN sources are in southern Lake Michigan. Within the LADCO region, IN sources have the greatest influence on O_3 concentrations in southern IL, southern MI, and central OH. CAMx estimated similar O_3 impacts for IN as for IL in the coastal areas in the Northeast and in the Gulf Coast.

The CAMx estimates for MI O_3 tracers in Figure 17 show a domain maximum contribution of 38.4 ppbV with the greatest impacts over Lakes Michigan, Ontario, and Erie. Within the LADCO states, MI sources have the greatest influence on O_3 concentrations in northern IN and OH. MI is also estimated to have a slightly greater impact on O_3 in the Northeast than both IL and IN, with maximum O_3 tracer concentrations of 4-6 ppbV extending off the Northeast coast.

Figure 18 shows that the maximum O_3 impact from MN sources is estimated to be 50.1 ppbV and occurs around the Twin Cities. MN has the greatest regional influence on O_3 concentrations in northern WI. The MN O_3 tracers are estimated to extend as far south as Dallas and east into central PA.

Figure 19 shows that OH sources have the greatest impact on O_3 over Lake Erie with a domain maximum tracer concentration of 63.1 ppbV. Within the LADCO region, OH sources are estimated to have the greatest impact on O_3 in eastern IN and southeastern MI. As the easternmost LADCO state, OH is estimated to have the greatest impact on O_3 in the Northeast, with maximum OH tracer concentrations of 8-10 ppbV extending to the Northeast

As shown in Figure 20, WI sources are estimated by CAMx to have the greatest impact on O_3 concentrations along the WI shoreline of Lake Michigan. The highest WI O_3 tracer concentration of 41.2 ppbV occurs over Lake Michigan off the southeast coast of the state. Within the region, WI sources have the greatest influence on O_3 concentrations in western MI and the far northeast corner of IL. CAMx estimates that WI sources influence O_3 concentrations as far away as northeast TX and along the Northeast U.S. coast by a maximum range of 2-4 ppbV.

Figure 21 shows that TX sources are estimated to impact O_3 concentrations in all of the LADCO states. The great influence from TX sources on O_3 in the region are estimated by CAMx to be in southern IL and southern WI by a maximum of 8-10 ppbV. The O_3 tracer from offshore sources shown in Figure 22 has relatively small impacts on O_3 in the LADCO states. Figure 23 shows that sources in Canada and Mexico are estimated by CAMx to influence O_3 concentrations through most of the Continental U.S. The largest influence in the LADCO region is near the Canadian border in eastern MI. Canadian emissions are estimated to impact most of the LADCO states by a seasonal maximum of 2-10 ppbV.

5.4 Interstate Transport Assessment Flexibilities

In March 2018 EPA released a memo (US EPA, 2018) the described a series of flexibilities that states could consider in developing Good Neighbor SIPs for the 2015 O_3 NAAQS. In this section LADCO presents a series of alternatives for calculating DVFs. We compare the results against the standard US EPA attainment test configuration (top 10 modeled days, 3x3 cell matrix around the monitor, including water cells) to demonstrate how the air quality projections and conclusions may change with each approach.

5.4.1 Alternative Power Sector Modeling

The "[u]se of alternative power sector modeling consistent with EPA's emissions inventory guidance" is presented in the Analytics section of EPA's March 2018 memo as a flexibility to consider in preparing a Good Neighbor SIP. This flexibility supports LADCO's use of the ERTAC EGU model for projecting EGU emissions to 2023. As described in Section 2.5.1, we consider the emissions projections from ERTAC EGU to be more representative of the sources in the Midwest and Northeast than the approach used by EPA in their 2023 EN modeling platform. As ERTAC EGU is developed in collaboration between regional and state air planning agencies, it includes algorithms and data that have been reviewed by many of the states impacted by interstate O_3 transport in the Eastern U.S.

The LADCO 2023 CAMx simulation relative to the EPA 2023 EN simulation is an example of an alternative power sector modeling flexibility. The only configuration difference between these simulations is in the EGU emissions used with CAMx to project future year air quality. This sensitivity is slightly confounded by differences in the EPA and LADCO computing platforms when directly comparing the runs. The computing system porting differences between the two runs is relatively small (see Section 5.1) compared to the differences introduced by changing the EGU emissions.

Figure 9 and Figure 10 illustrate the differences in 2023 MDA8 O_3 that result from changing the EGU projection methodology. As described in Section 5.2, the EPA simulation predicts higher O_3 in the Midwest, Northeast, Gulf Coast, and Pacific Coast states; the LADCO simulation predicts higher O_3 in the Four Corners region and Central Arkansas. Figure 24 and Figure 25 compare summer season MDA8 O_3 between the LADCO and EPA 2023 simulations for monitors in the AQS and CASTNET networks, respectively. The LADCO simulation (y-axis) predicts slightly lower O_3 concentrations across all sites (AQS NMB = -0.89%, CASTNET NMB = -0.4%).

Figure 26 and Figure 27 compare the EPA and LADCO 2023 DVFs for the Eastern US and the LADCO region, respectively. Table 7 shows the DVFs and DVCs for the nonattainment and maintenance monitors in the Eastern U.S. ***The LADCO simulation that used ERTAC EGU emissions projections forecasts lower DVFs than the EPA 2023 EN simulation. All six of the projected nonattainment monitors in the EPA simulation are forecasted by the LADCO simulation to be in attainment.*** The RRF plots in Figure 28 further show the regional O_3 reductions in the LADCO simulation relative to the EPA 2023 EN simulation. More yellow and blue colors, representing lower RRFs or greater reductions in future year O_3, are seen in the LADCO simulation through the Great Lakes, Mid-Atlantic, and Northeast regions.

5.4.2 Impacts of Water Cells on Design Values

Confidence in the ability of photochemical models to accurately estimate O_3 over water is a persistent concern with the use of the models for air quality planning. This concern recently prompted measurement campaigns in the Eastern U.S. to address the issue (see Lake Michigan Ozone Study and Long Island Sound Tropospheric Ozone Study). The meteorology and chemistry processes in model grid cells that are dominated by water (> 50% landuse area) are a challenge to simulate because the conventional technical formulations of the models were not optimized for water cells. Even with the introduction of new algorithms to simulate the dynamical and chemical features of water cells, a lack of over-water observations hinders our ability to verify the accuracy of the models in simulating these conditions. In consideration that the models may not perform well in simulating water cells, EPA and others have presented alterative DVF calculation approaches that exclude water cells. Although not explicitly listed in Attachment A of the EPA's March 2018 memo on O_3 Transport Modeling as a flexibility to consider in developing a Good Neighbor SIP, the EPA used the exclusion of water cells in their own DVF calculations (US EPA, 2017a; US EPA, 2018). EPA implicitly endorses the exclusion of water cells when calculating DVFs in their most recent technical guidance for Good Neighbor SIPs (US EPA, 2018).

Exercising this flexibility does not require additional CAMx simulations. It is implemented through a postprocessing sequence per EPA (2018) in which model grid cells that are dominated by water (> 50% landuse area) are removed from the 3x3 matrix in the RRF and DVF calculation. One important modification to this process is to override the exclusion condition for cells that contain monitors; in other words, grid cells that contain monitors will be included in the 3x3 matrix regardless of the amount of water coverage in the cell. For the results presented here, LADCO used EPA postprocessing utilities and scripts that were developed to support their March 2018 memo.

Figure 29, Figure 30, and Table 8 present the impacts of excluding water cells in the DVF calculations for the LADCO and EPA 2023 simulations. Figure 29 and Figure 30 compare the water/no-water DVFs and RRFs for the LADCO simulation, respectively. ***In general, including water cells in the attainment test calculation results in lower DVFs for the lakeshore monitors in the LADCO region.*** A few key downwind monitors (Harford, MD; Richmond, NY; New Haven, CT) have higher DVFs when water cells are included in the calculation.

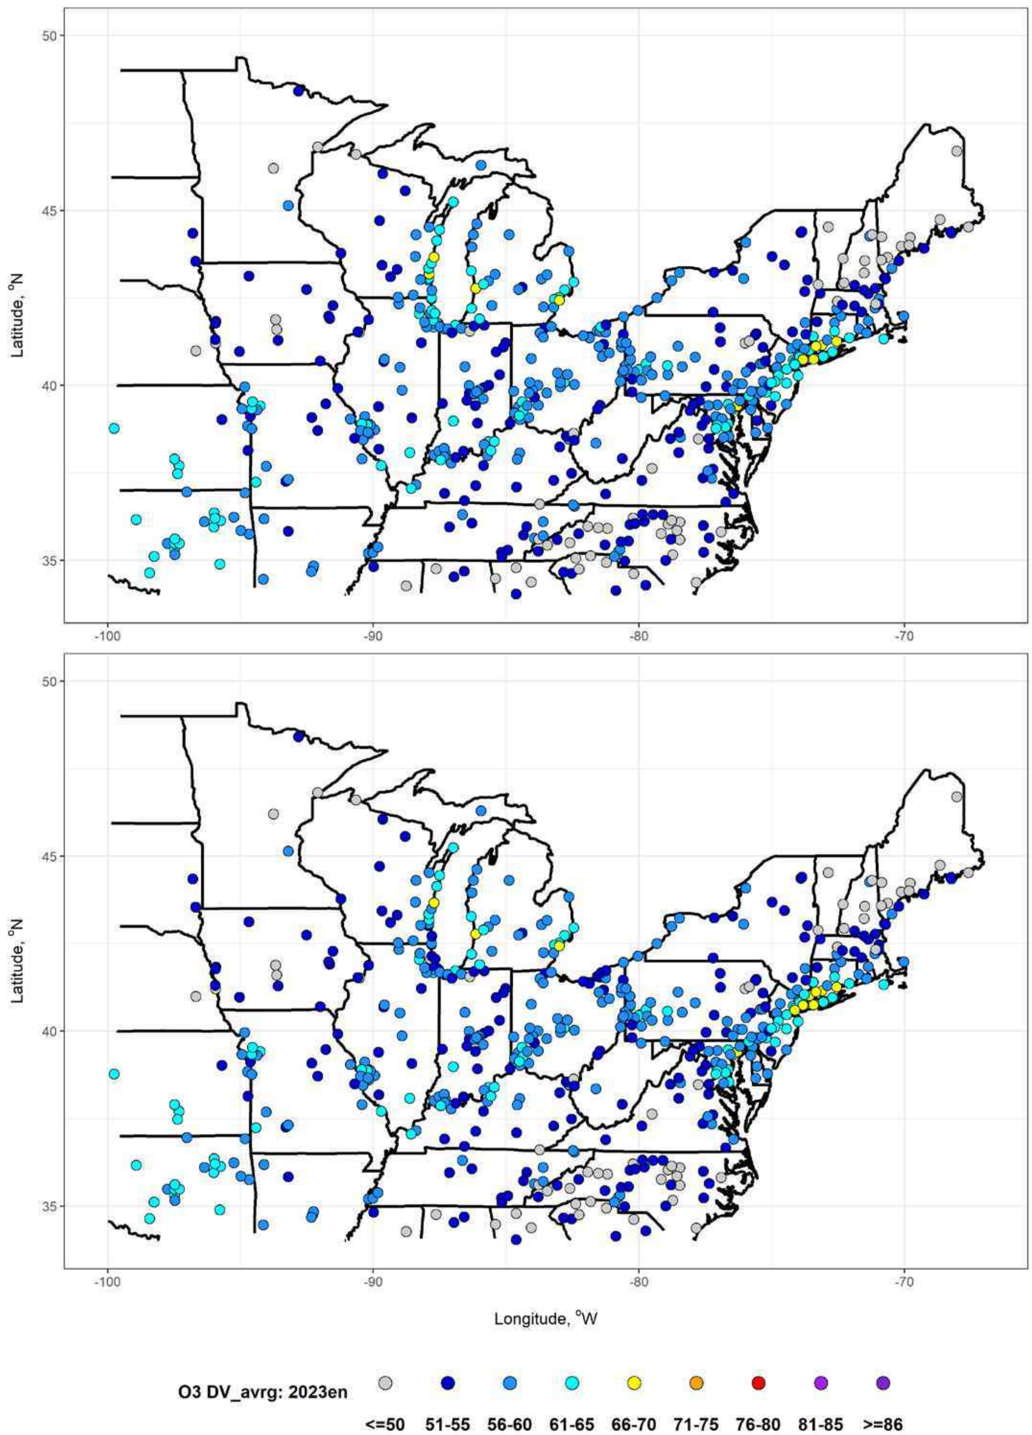

Figure 29. Ozone DVFs calculated with water cells excluded (top) and included (bottom) for the LADCO 2023 CAMx simulation.

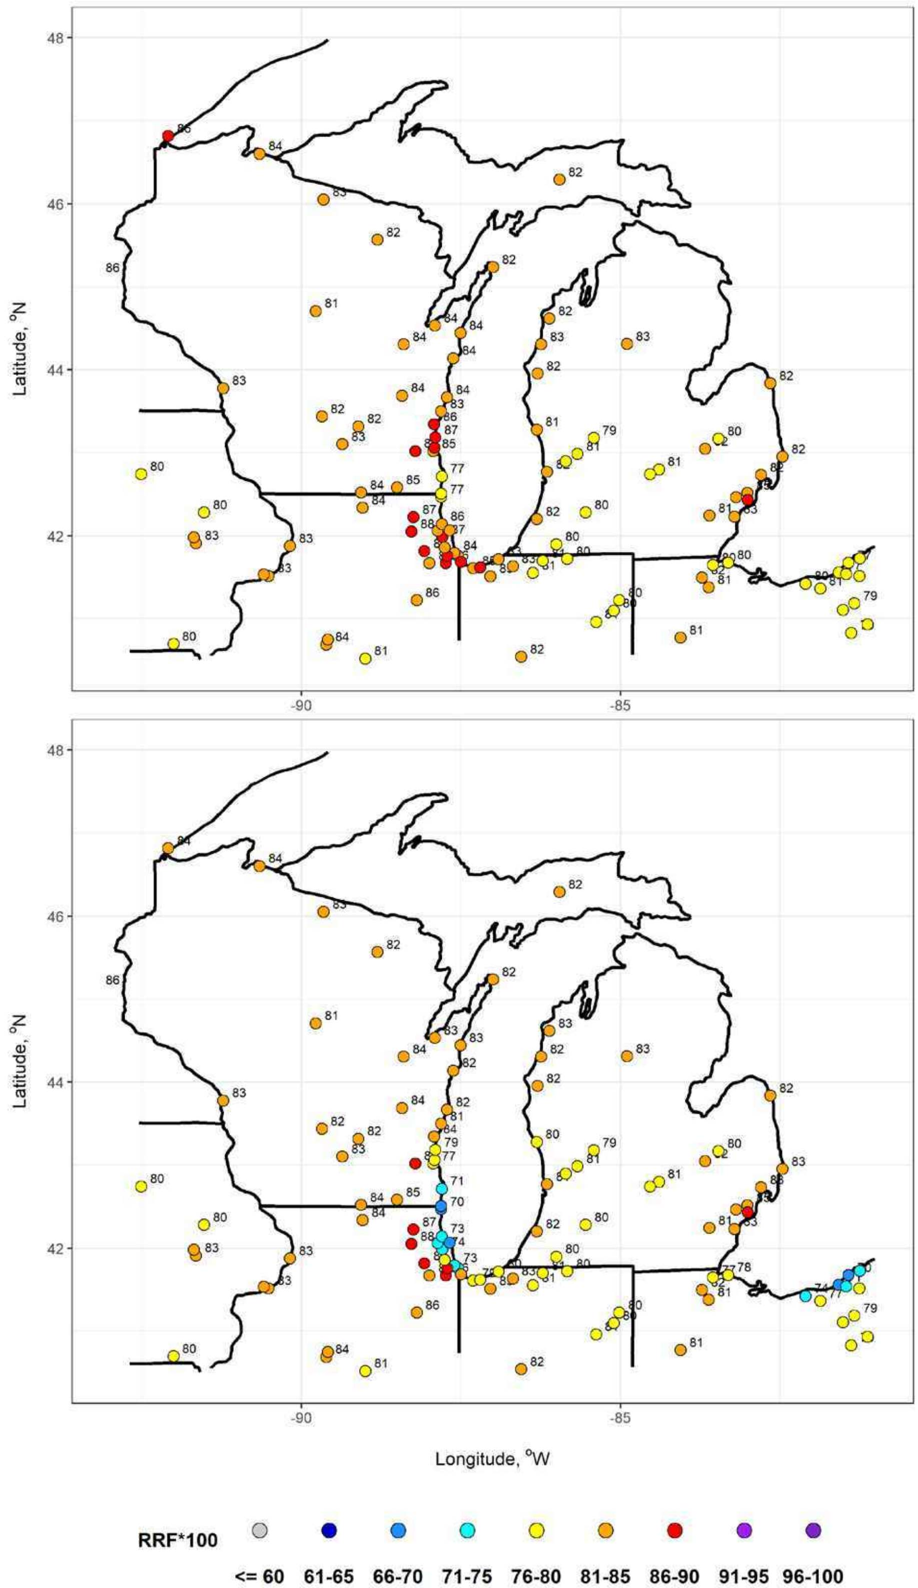

Figure 30. Ozone RRFs calculated with water cells excluded (top) and included (bottom) for the LADCO 2023 CAMx simulation.

5.4.3 Model Bias Filtering

Under the Step 1 flexibilities for Good Neighbor SIP analyses in the EPA March 2018 memo, EPA says that states may "[c]onsider removal of certain data from modeling analysis for the purposes of projecting design values and calculating the contribution metric where data removal is based on model performance and technical analyses support the exclusion." Per this flexibility, for the monitors analyzed in this document LADCO filtered the days used for calculating RRFs and DVFs with an absolute bias threshold of 15%. Instead of calculating RRFs at each monitor from the 10 highest concentration MDA8 modeled days in the base year, we used the 10 highest days with absolute biases <= 15%. We applied the bias filtering to the attainment test calculations that include water cells.

Table 9 and Table 10 compare the LADCO and EPA O_3 DVFs and RRFs with and without bias filtering. The change in the LADCO average DVFs from applying the bias filtering ranged from a 2.2% decrease for the Fairfield, CT (AIRS ID: 90019003) monitor to a 4.8% increase for the Milwaukee, WI (AIRS ID: 550790085) monitor. Although the percentage differences from applying the bias filters are not exactly the same between the two CAMx simulations, the impacts to the EPA average DVFs was proportional to the LADCO DVF calculations. In other words, the bias filtering causes the DVFs to change in the same direction for both simulations. The bias filtering also had comparable impacts on both the average and maximum DVFs. ***Applying the bias filter increases the DVFs at the Sheboygan, WI; Allegan, MI, and Milwaukee, WI monitors; the DVF at the Wayne, MI monitor decreases with the application of the bias filter.*** It should be noted that the bias filtering has more of an impact on the DVFs when water cells are included in the attainment test calculations (these results are not shown here).

ERTAC EGU Committee

Contents

Introduction

The ERTAC Electricity Generating Unit (EGU) Committee develops reference runs for the continental United States (CONUS). CONUS 2.7 is based on 2011 base year continuous emission monitoring (CEM) data and growth factors from the AEO2017 projection that does not include the Clean Power Plan (US Energy Information Administration January 2017). Input files to version 2.7, were developed using input received by June 2017 from a significant outreach effort to states and stakeholders. Final V2.7 runs were done by VA DEQ and OTC in September 2017. The contact person for questions about these run files is Doris McLeod (804-698-4197) for all runs except 2023. For 2023, the contact person is Joseph Jakuta (jjakuta@otcair.org). CONUS 2.7 includes both a reference run and a Cross State Air Pollution Update (CSAPR Update) Rule (81 FR 74504) compliant scenario. The reference run includes only unit change information provided by states. The CSAPR Update compliant run include additional unit adjustments, described further in this text, agreed upon by the ERTAC EGU committee to represent the EGU sector operating in compliance with the CSAPR Update rule. Projections for reference case runs have been prepared for years 2017, 2018, 2019, 2020, 2023, 2025, and 2030. Projections for CSAPR Update compliant scenario have been prepared for years 2020, 2023, 2025, 2028, and 2030. The CSAPR Update compliant files are described also as optimized runs. File names that pertain to the CSAPR Update compliant run include the "opt" identifier in file names.

The ERTAC EGU Committee maintains and distributes reference runs for the continental United States (CONUS), including the hourly input, output, summary, and documentation files for each run. These reference runs and the CSPR Update Compliant Scenario and complete documentation of the ERTAC EGU Tool is located on the MARAMA web site located here:

http://www.marama.org/2013-ertac-egu-forecasting-tool-documentation

ERTAC Input Files

The ERTAC EGU Tool input files are built by the ERTAC leadership committee from a wide variety of existing data. These input files are subject to periodic quality assurance and updating by state agency staff. Agencies provide information on new units and controls, fuel switches, shutdowns and other unit-specific changes. In addition, the ERTAC EGU growth committee prepares updates to the growth factors when new versions of the Energy Information Agency (EIA) Annual Energy Outlook (AEO) become available. Periodic updates of these input files drive creation of new run versions. The ERTAC EGU tool projects fossil fuel fired units that report emissions to USEPA Clean Air Markets Division (CAMD) and serve a generator of at least 25 MW (there are some exemptions in the North East where units are sized less than 25 MW).

A key data source are the hourly reports of generation and emissions collected by CEM and electronically reported to CAMD by facilities for the base year, in this case 2011. Base year SO_2 and NO_X emission rates (lb/mmbtu) are calculated from this data. Future emission rates are developed from base year rates adjusted to account for state knowledge of expected emission controls, fuel switches, retirements, and new units.

The primary sources of expected future change in generation is the Energy Information Agency (EIA) annual projection of future generation and the National Energy Reliability Corporation (NERC) projection of peak generation rates. This information is available by region and fuel type. Where states have local projections these are preferred over national sources. Future generation by unit is estimated by merging these national, regional and state growth files with state knowledge of unit level changes. Hourly future emissions of NO_X and SO_2 are calculated by multiplying hourly projected future heat input by future emission rates.

ERTAC EGU Tool input files are as follows:

- **Base Year Hourly CEM data** – This comma separated file contains hourly unit level generation and emissions data extracted from EPA's CAMD database. In unit-specific situations where base year hourly data needs to be modified, users provide a non-CAMD hourly file, which may be used to adjust or add data to the base year hourly CEM file.

- **Unit Availability File (UAF)** – This tabular file contains descriptions of each generating unit derived from a variety of sources, including the CAMD NEEDS database, state input, EIA Form 860, and NERC data. Each row in the table represents a single generating unit. This file is maintained and updated by the ERTAC committee and provides information on changes to specific units from the base to the future year. For example, the UAF captures actual or planned changes to utilization fractions, unit efficiency, capacity, or fuels. State/Local/Tribal (S/L/T) agencies also add information on actual and planned new units and shutdowns.

- **Control File** – This tabular file contains known future unit specific changes to SO_2 or NO_X emission rates (in terms of lbs/mmBtu) and/or control efficiencies (for example, addition of a scrubber or selective catalytic reduction system). This information is provided by S/L/T agency staff. This file also provides emission rates for units that did not operate in the base year.

- **Seasonal Controls File** – This optional tabular file may be used by S/L/T agencies to enter seasonal or periodic future year emissions rates for specific units for use in future year runs. This file may be used in addition to, or as an alternative to, the Control File.

- **Input Variables File** – This tabular file specifies values for a number of variables used in a particular projection run.

    - **Regions and Fuel Characteristics** are not hardwired into the model. Rather, the regions and their characteristics are specified in the Input Variables File. This file allows the S/L/T agencies to specify variables such as the size, fuel type and location for new units. In addition, the regional scheme and fuel types are specified in this file.

    - **Default New Unit Emission Rates.** Percentile of best performing existing unit emission rates for use in new units. Default is 90th percentile.

    - **New Unit Hourly Profile Characteristics.** For new planned units and generation deficit units (GDUs), users may specify in this file the percentile ranking of the existing unit (operated in the base year) used to create a representative future profile of activity for new units and GDUs.

- **Growth Factor File** – This tabular file contains the annual, nonpeak and peak electrical generation growth factors delineated by geographic region and generating unit type used in a particular run.

    - **Peak Growth and Transition Hours**. The number of peak and transition hours, differentiated by fuel and region, are assigned in the Growth Factor File.

- **Demand Transfer File** – This optional file allows users to transfer power, on an hourly basis, from one region/fuel-unit type to another. It also allows transfer to or from other, non-fossil fuel fired systems such as nuclear and renewables.

Growth factors

Generation for future years by fuel type are based on growth rates which are differentiated by annual, nonpeak, and peak rates.

Annual growth rates are developed by the ERTAC EGU Growth subcommittee from the EIA Annual Energy Outlook (AEO) and NERC projections. In certain cases, S/L/T agencies have developed more refined region specific growth factors which are then used to replace the EIA/NERC factors developed from other information sources, along with supporting documentation for those growth rates. EIA annual average regional growth factors are calculated by dividing AEO future projected generation by base year generation.

Peak growth rates are derived by determining relative peak growth from NERC Electricity Supply & Demand (ES&D) data and applying it to the annual growth rates. The derived relative peak growth rates are not delineated by fuel so the ratio of peak to nonpeak growth rates for each fuel within a single region is constant.

Nonpeak growth rates are calculated within the ERTAC EGU Tool using annual and peak growth rates. Annual average regional growth rates are adjusted to account for the peak hours.

Peak and nonpeak growth is assigned to every hour by ordering all hours of the year by base year utilization. The peak growth factor is assigned by fuel to a limited number of hours with the highest utilization in the base year. Growth is then transitioned gradually to non-peak growth rate. The number of peak and transition hours are differentiated by fuel and region and are assigned in the Input Variables File. Figure 1 shows graphically the relationship between annual, peak and nonpeak growth rates.

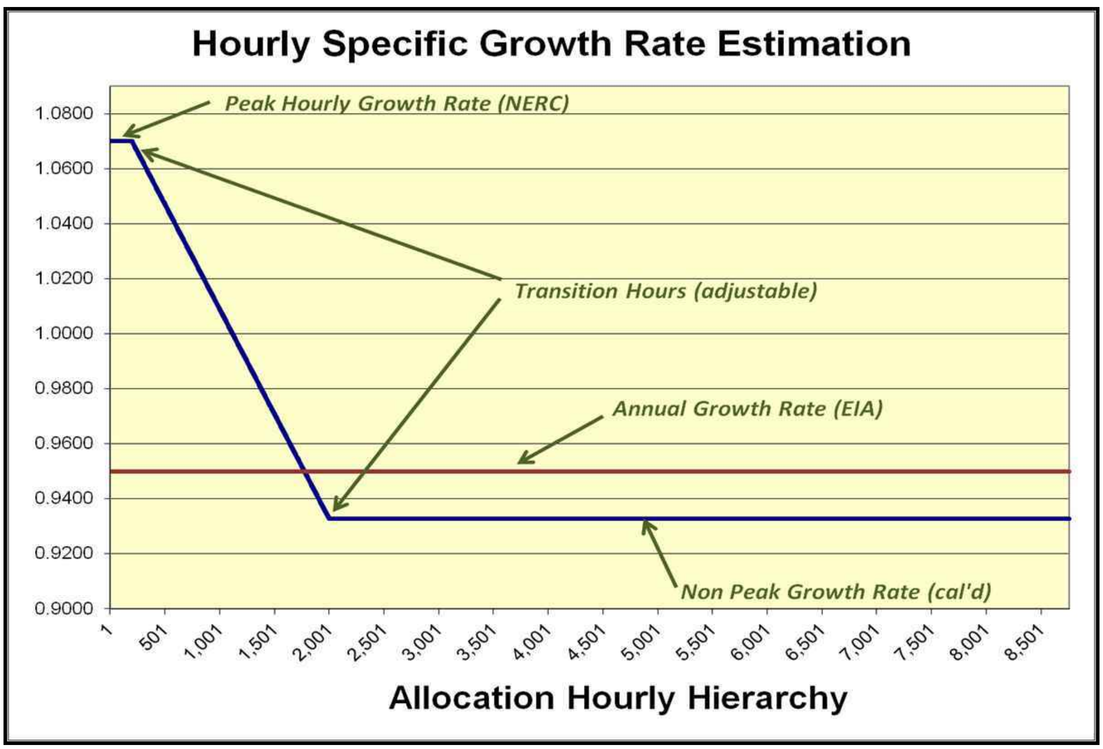

Figure 1. Relationship between the annual, peak, and nonpeak growth rates

Finally, fuel specific hourly regional growth factors are adjusted to account for activity from new units and shutdowns. The tool then applies the adjusted hourly growth factors to the base year hourly generation data to estimate hourly future generation. This generation is assigned to the units burning the specified fuel within the region. After generation is assigned, the tool confirms that unit capacity is not exceeded. If the available capacity is fully utilized new, generic units ("Generation Deficit Units") are created to carry demand that exceeds known unit capacity.

NO_X and SO_2 Emissions

For base year runs, actual CAMD data is averaged to calculate base year ozone season and non-ozone season emission rates.

For future year runs, calculated base year average emission rates for existing units are adjusted to account for new control equipment or other changes provided in the input files.

For new units, two approaches are employed. First, if a state provides new unit emission rates those are used directly. Where emission rates are not provided, these are estimated based on the 90th percentile best performing existing unit for that fuel type and region. The user may adjust this percentile within the input variables file. These rates are applied to each unit's future generation to calculate NO_X and SO_2 emissions.

Output

The ERTAC tool generates hourly generation and emissions for each unit included in the system. In addition, post processors create summary files to facilitate review of the results, as follows:

- Annual base and future year generation (MW-hrs), heat input (mmbtu), SO_2, NO_X emission (tons) and average emission rate (lbs/mmbtu)
- Ozone season base and future year generation and heat input, NO_X emission (tons) and average emission rate (lbs/mmbtu)

Post processors are also available to generate CO_2 estimates.

Geographic Regional System

Each EGU unit included in the model is assigned to a geographic region and fuel type bin in the Unit Availability File. The geographic regional system provided in Figure 2 is used in versions 2.7 reference and CSAPR Update compliant runs is the EIA Electricity Market Module (EMM) regional system. One adjustment that the EIA EMM system for the ERTAC EGU system is that SPNO and SPSO have been combined into a single region.

Because the EIA EMM and NERC regions are not identical, adjustment is required to align these regional systems to develop annual and peak growth rates. To match EIA and NERC, a "best fit" NERC regional growth factor is assigned to each EMM region. In the simplest case, where a clear match between EIA and NERC regional schemes exists, for example NPCC-New England, the NERC relative peak growth rate is assigned to the corresponding EMM region. In more complicated cases, where multiple EMM regions corresponded to a single NERC region, or where regions were organized along substantially different geographic boundaries, the NERC ES&D data was aggregated and averaged to generate a relative peak growth factor for the (usually larger) corresponding NERC region and was applied to the corresponding ERTAC region (which closely resemble the EMM regions). As an example, the EIA SRVC, RFCW, and RFCE regions corresponds to two NERC regions, PJM and SERC East. In this case, the relative peak growth factors were derived from PJM and SERC East and applied to SRVC, RFCW, and RFCE ERTAC regions.

Within each region, individual generation units are further delineated into five unit types as follows:

- Coal;
- Oil;
- Natural Gas – Combined Cycle;
- Natural Gas – Single Cycle;
- Natural Gas – Boiler gas.

Figure 2: Regional boundaries for coal generation, CONUSv2.7

DETAILS OF VERSION 2.7 REFERENCE AND CSAPR UPDATE COMPLIANT RUNS

ERTAC EGU v2.7 was built on improvements to prior runs and included updates to the UAF and control file from states received as of July. A summary of the inputs used to develop the ERTAC EGU v2.7 Reference and CSPAR Compliant runs for the continental United States are shown in Figures 5 and 6 respectively. Details of these changes may be found in the change log document. (ERTAC 2017a)

ERTAC EGU CODE 2.1 – BOTH V2.7 REFERENCE AND CSAPR UPDATE COMPLIANT SCENARIO

Version 2.7 was the first usage of the ERTAC EGU v2.1 code. V2.1 added a new functionality, including the ability to transfer of load between fuel types and regions. Use of this transfer functionality is described later in this document. (ERTAC 2017b)

REGIONAL BOUNDARIES GROWTH RATES– BOTH V2.7 REFERENCE AND CSAPR UPDATE COMPLIANT SCENARIO

AEO regions SPSO and SPNO were aggregated into a single region called SPPR for the coal fuel type only. - SPP operates as a single balancing authority and single wholesale market for the SPPR region. Hence growth in wholesale power production occurs within that single market construct. Application of differential growth rates by fuel type between SPPS and SPPN obscures that single market construct and can produce counter-intuitive fuel-specific emissions forecasts. Combining the individual net generation forecasts for a single fuel type allows for an accurate averaging of the growth rates into an integrated whole. The anticipated outcome will be more reflective of the generation efficiencies and relative fuel balance based on the application of a single wholesale market construct. Since there have been issues of predicted over-emissions in one or more of the states (most notably Oklahoma) when forecasting the two independent smaller regions within the ERTAC construct, the bigger regional footprint partially alleviates this specific problem due to the rebalanced loading for each fuel-unit type.

GROWTH RATES – BOTH V2.7 REFERENCE AND CSAPR UPDATE COMPLIANT SCENARIO

Growth factors used in both v2.7 reference and CSAPR Update compliant scenario were developed based on AEO2017 No Clean Power Plan Case. Relative peak factors were derived from 2016 NERC Electricity Supply & Demand (ES&D). The file containing annual and peak growth factors was provided by Tom Shanley of the ERTAC EGU Growth committee and is named:

CONUSv2.7_AEO2017Ref_noCPP_SPPR_T2017_2030_ertac_growth_rates_7-17-2017.xlsx

These growth factors and default growth curve parameters were used with the following exceptions:

- **SRVC**[1] replaced AEO growth rates and growth curve shape with values based on regional knowledge for combined cycle, Boiler gas and simple cycle fuel bins. The updated local values were used for all future year projections. Development of the local values is described in a memo included as an appendix to this document. Specific changes include:
    - **Combined Cycle** peak to nonpeak growth transition points were set to 200 and 2000 to reflect the fairly large difference in average and peak growth rates (AGR and PGR).
    - **Boiler Gas and Simple Cycle** transition points were set to 100 and 1000 to reflect the large difference in AGR and PGR and ameliorate the Generation Deficit Units (GDU)
    - Any year not included in the SRVC memo was interpolated between SRVC information.

[1] updated using PGR/AGR information in email dated August 8, 2017, transmitted via email from Ming Xie of NC on August 9, 2017.

- **NYCW**[2] replaced AEO annual growth rates with values based on regional knowledge for all fuel bins. The updated local values were developed for 2020 and 2025 and interpolated[3] for use for all future year projections. Development of the local values is described in a memo included as an appendix to this document. Specific changes include: xxx
- **RFCE and RFCM** default growth curve transition points for the combined cycle fuel bin (CC) were replaced with 100 and 1000 to reflect the large growth and increased reliance on CC for base loaded operation in those regions.
- **SRGW** boiler gas peak growth rate for 2028 and 2030 was reduced to 0.98 so that the infinite GDU bug is not triggered. Annual growth rate was not affected.

ERTAC Demand Transfer– Both V2.7 Reference and CSAPR Update compliant Scenario

Demand transfer is a new concept made possible by use of the new v2.1 ERTAC EGU code. The concept is to transfer some demand for particular hours from one fuel bin to alleviate the generation of a GDU. Another use for a demand transfer is the case where a significant system change occurs which was not anticipated by the EIA in the AEO. The example in V2.7 is the retirement of a large nuclear power plant near New York City. This results in other fuel bins having to provide a large amount of generation that was unanticipated by the EIA in the AEO.

Transfers to prevent a coal fired GDU

- **NEWE** 300 MW-hrs was transferred from coal to combined cycle fuel bins in 861 deficit hours to prevent a coal fired GDU. There were 2000 MWs of unused CC capacity in NEWE. This transfer was done in every future year projected.
- **FRCC** Coal generation was transferred to the combined cycle fuel bin for certain hours to prevent a coal fired GDU. There was significant unused combined cycle capacity in FRCC.[4] This transfer was done in every future year projected. However, the amount of generation transferred, and the number of hours required varied by projection year as follows:
    - 2017 – No transfer required
    - 2018 – 2500 MW-hr coal to CC in 1259 deficit hours
    - 2019 – 1000 MW-hr coal to CC in 241 deficit hours
    - 2020 – 1300 MW-hr coal to CC in 444 deficit hours
    - 2023 – 600 MW-hr coal to CC in 59 deficit hours
    - 2025 – 600 MW-hr coal to CC in 90 deficit hours
    - 2028 – 1000 MW-hr coal to CC in 2040 deficit hours
    - 2030 – 1000 MW-hr coal to CC in 239 deficit hours

---

[2] NY memo to MARAMA, dated 02-11-2016

[3] 2020 interpolated growth rates were approved by Ona Papageorgiou (NY) in an email dated 8/1/2017 from Ona to D. McLeod (VA)

[4] FL staff (Hastings Read) approved this approach in an email dated August 9, 2017, to D. McLeod, titled, "RE: FRCC updates for ERTAC CONUS2.7.

Transfers to ameliorate disappearing generation bug

- **RFCE** – In the 2023 and 2025 projection 300 MWh of coal generation in RFCE was transferred to Combined Cycle for each of 4 hours to ameliorate missing generation due to Utilization Fraction limitations on coal fired units. The table below shows the 4 hours. RFCE combined cycle has significant new capacity in 2023, and at least 1000 MW of unused capacity.

Transfers to address nuclear retirement

- **NYCW** - Indian Point nuclear power plant is scheduled to retire in 2021. John Barnes of NY (email dated 7/13/2017) advised that the nuclear transfers should be limited to years after 2021. (2021/2023/2028)

INPUT VARIABLES – BOTH V2.7 REFERENCE AND CSAPR UPDATE COMPLIANT SCENARIO

In SRVC the combined cycle percentile was set at 50th, coal to 70%, and simple cycle to 70th. This was based on region specific sizes, capacities, and characteristics.

NON-CAMD HOURLY FILE– BOTH V2.7 REFERENCE AND CSAPR UPDATE COMPLIANT SCENARIO

A small group of units with abnormal or missing base year hourly data are not assigned any generation by the tool in the future year. To correct this issue, these units are assigned one hour of reasonable, minimal activity in the non-CAMD hourly file to ensure processing. This improvement has negligible impact on base year data.

For ORIS 55178, CT-1 it appears in some hours this unit reported in KW-hr rather than MW-hr, so that certain hours had more than 20,000 MW-hr of production. To correct this issue, any reported load greater than 300 was changed to 300 to fix the 2011 anomalous data. This issue was not discovered in previous runs because the unit had been marked "non-EGU" in prior runs. The state updated this designation to "Full" in the 2.7 comment period, so that the anomalous data became apparent in trial runs[5].

MI and FL supplied gross load data for combined cycle units that did not report power produced from steam generation in the BY CAMD data.

---

[5] See email from Adel Alsharafi (MO) dated 7/20/2017 to D. McLeod (VA)

Negative emissions and load values are replaced with zero.

Added a full year of data for:

- ORIS 8906 (Astoria) Unit IDs 30, 40, and 50—summed reheat and superheat reported data to create the pseudo units.
- ORIS 7839 (Ladysmith) Unit 5, which is equivalent to that reported in 2011 for 7838 (Remington) Unit 5. 7838, 5 does not exist. This is a 2011 CAMD reporting error.

Other similar anomalies were corrected and are documented in the Run Log.

Unit Availability File – Both V2.7 Reference and CSAPR Update compliant Scenario

Numerous detailed corrections and adjustments to these files were made for both v2.7 reference and CSAPR Update compliant runs based on S/L/T agency comments regarding the configuration, characteristics, and utilization estimates of their units. The file name for the final unit availability file is: 2011BASEUnit_Availability_v2.7_17noCPPSeptember 192017_code2_1.xls.

Boiler gas treatment: Many coal fired EGU units have recently announced conversions to firing as boiler gas units. This trend results in a future over-capacity of boiler gas capacity and shortfall of coal capacity compared with projected generation in many regions. These conversions have been left in the coal bin in several cases for two reasons:

- To address shortfall created in coal bin resulting in GDU formation to meet coal fired demand.
- To create a reasonable future year generation profile for the unit.

To address the shortfall the tool created coal fired Generation Deficit Units to meet the demand for coal fired generation. To ameliorate this imbalance, a decision was made to assign boiler gas characteristics, including emission rates to these units, but to leave them in the coal fuel bin. These units were assigned Utilization fractions typical of existing natural gas-fired boilers in their region. The following units were treated in this fashion:

- 6055, 2B1 (Big Cajun 2, LA) in SRDA. Coal to boiler gas conversion assigned a UF limitation of 0.5
- Xxxx We need a complete list of the units treated in this fashion.

Controls File/Seasonal Controls File - Application of Best Practices NO_X Control Rates to EGU Units With Existing Control Devices – V2.7 CSAPR Update compliant Scenario Only

ERTAC EGU V2.7 reference runs did not result in NO_X emissions that met the regulatory requirement to meet the 2017/2018 CSAPR Update budgets in FY 2023. Due to the conservative nature of SIP development and therefore inventory development, states may not always include lower ozone season NO_X rates in projections for units that have flexibility in how they run controls or combustion processes. To address this issue, the ERTAC committee developed the CSAPR Update scenario to reflect reasonable estimates of improved NO_X rates driven by the requirement to purchase allowances under CSAPR Update in future year projections to demonstrate a first-cut estimate of compliance with state level budgets, assurance levels, or regional budgets associated with the CSAPR Update rule addressing the 2008 ozone NAAQS. Files resulting from this approach to editing the control file and seasonal control file for each run are referred to as the “optimized files.” These changes are fully described in the control documentation file titled, "2011BASEControl File-v2.7_17noCPPSeptember 19,2017_code2_1.xls." The descriptions below are background and summaries of the control documentation file.

Development of optimized emission rates. - MD staff prepared an analysis of historical unit performance from 2005-2016 ozone seasons to determine historically best-observed NO_X emission rates for coal-fired units controlled by SCR or SNCR. (Vinciguerra et al 2017) This analysis was based on ERTAC 2.6 results. Based on this analysis it was estimated that 19 units fitted with SNCR could meet an average NO_X rate of 0.125 lbs/mmbtu in the ozone season. Also 141 units fitted with SCR were identified that could meet an average NO_X rate of 0.064 lbs/mmbtu in the ozone season. These average values were selected to represent optimized NO_X rates during the ozone season in the absence of a state-provided optimized NO_X rate. These values may be further updated in later runs to reflect rates from unit-specific analyses.[6] Additionally, OK staff prepared an analysis of ozone season NO_X rates for units within OK not equipped with post-combustion controls but that have reduced NO_X emissions in 2016 based on CAMD data.[7]

Units for which the optimized control rate were applied - To determine which units would receive optimized NO_X rates, Maryland developed a list of coal-fired EGUs within CSAPR states equipped with SCR or SNCR, and matched this list to the ERTAC 2.7 2023 results. The optimized NO_X rates were applied to SNCR units with a 2023 ozone season NO_X emission rate > 0.125 lbs/mmbtu and SCR units with a 2023 ozone season NO_X rate > 0.064 lbs/mmbtu unless the state already provided an ozone season controlled NO_X rate in the seasonal control file. This resulted in optimized OS rates for 163 units – 124 SCR and 39 SNCR units.

Oklahoma Units – Oklahoma submitted optimized ozone season NO_X rates for the CSAPR Update compliant run for the following additional units not included in Maryland's analysis. These rates are based on 2016 ozone season NO_X data as reported by the Oklahoma units to CAMD. For all units except 2952 Unit 6, the non ozone season rates were based on submitted data in the documentation controls file. For 2952, Unit 6, which had no submitted data, the non-ozone season rates were those supplied by the tool as the non-ozone season average in 2011.

Optimized control emission rates were only applied in the ozone season - The optimized rates were included in the seasonal controls files and applied from May 1 through Sept 30 each year, beginning in 2017. In other periods of the year emission factors were equivalent to the 2011 data for the non-ozone season unless states had provided controlled NO_X rates as inputs. Where states provided a future year controlled NO_X rate that controlled rate was used for the non-ozone season. State provided annual NO_X control information for optimized units was removed from the annual control file to ensure that the ERTAC EGU tool would correctly select the NO_X rate supplied in the optimized seasonal controls file. However, state comments concerning annual controls were preserved in the non-ozone seasonal control file records. The optimized controls file and seasonal controls file can be used for years 2020 and beyond with no further modifications to the files.

- **Controls file:**
  Based on 2011BASEControl File-v2.7_17noCPPSeptember 192017_code2_1.xls.

[6] Email dated 7/12/2017 from H. Ashenafi-MD to D. McLeod-VA contained the updated rates for the various ORIS code/Unit ID combinations.
[7] Email dated 8/3/2017 from T. Richardson-OK to D. McLeod-VA contained the updated rates for the various ORIS code/Unit ID combinations.

- **Seasonal Controls File:**
  Based on 2011BASEControl File-v2.7_17noCPPSeptember 1922017_code2_1.xls.
  The following items are documented in the controls file but are also worthy of explanation here:
  - North Carolina submitted a large number of new seasonal control records. For units with a pollutant in the seasonal controls file, those line items were deleted from the controls file. [8]

Figure XXX New Oklahoma Emission Rates based on 2016 CAMD

ORIS	Unit ID	Facility	State	ERTAC Region	Fuel/Unit Type Bin	Previously Submitted or Calculated OS NOx Rate, (lbs/mmbut)	Calc. 2016 CAMD OS NOx Rate (lb/MMBtu)
165	2	Grand River Dam Authority	OK	SPPR	Coal	0.1600	0.1461
2952	6	Muskogee	OK	SPPR	Coal	0.3391	0.2813
2956	1	Seminole (2956)	OK	SPPR	boiler gas	0.2030	0.1061
2956	2	Seminole (2956)	OK	SPPR	boiler gas	0.2120	0.0954
2963	3313	Northeastern	OK	SPPR	Coal	0.1500	0.1317
10671	1A	AES Shady Point	OK	SPPR	Coal	0.1225	0.0712
10671	1B	AES Shady Point	OK	SPPR	coal	0.1245	0.0716
10671	2A	AES Shady Point	OK	SPPR	coal	0.1262	0.0669
10671	2B	AES Shady Point	OK	SPPR	coal	0.1268	0.0662
50558	CC01	Oklahoma Cogeneration LLC	OK	SPPR	combined cycle gas	0.2000	0.1222

Prior Runs

Prior reference runs files and documentation using 2011 base year data are as follows:

v2.6 – Run in March, 2017, using input files current as of January 2017, and run by VA DEQ, IN DEP, and OTC in March 2017. Significant change in this run is that boiler gas units in many states, including PA were left in the coal bin and more seasonal controls were added, including MD. Growth factors are based on AEO2015 High Oil and Gas Scenario.

v2.5L2 - Run in August, 2016, using input files current as of August 2016, and run by VA DEQ. Growth factors are based on AEO2015 High Oil and Gas Scenario.

v2.4 – Run in August, 2015, using input files current as of July 2015, and run by VA DEQ. As occurred with v2.3, growth factors are based on AEO2014

v2.3 – Run in October 2014. This run included major updates to the UAF and Control files received as of August 24, 2014. This is the first use of growth rates from AEO2014.

v2.2 – Run in June 2014. Same as v2.1. This run included major updates to the UAF and Control files received as of March 31, 2014. This is the first use of the new code 1.01. Growth rates were from AEO2013.

v2.1L1 – Run in April 2014. Same as 2.1 except this run included updates from Midwest to UAF and control file for Indiana, Illinois, Wisconsin, Michigan and Ohio primarily for coal fired units received dated March 3, 2014.

v2.1 – Run in March 2014. This run included updates to the UAF and control file from several states. UAF updated with adequate data to calculate an ERTAC heat rate. Negative values in CAMD replaced with zero. An adjustment to implement zero growth for the Boiler gas was included. Combustion turbines and combined cycle units were adjusted in the 2.1 factors to account for the boiler-gas generation.

v2.0 – Run in January 2014. This run was the first using base year 2011. In addition, the Midwest states provided updates to the UAF and control files. These updates were completed by the Northeast in prior runs.

Figure 3 and summarize the inputs to v2.7 Reference and CSAPR Update compliant runs, respectively.

Figure 3: Inputs to ERTAC EGU v2.7 Projection Runs

ERTAC File Name	Description	Run Notes
OVERVIEW	Version 2.7	Run by VA DEQ - Doris McLeod , OTC-Joseph Jakuta in Aug-Sep 2017
	Code: 2.1	New code, with new ertac_demand_transfer feature. Also, used a file converter for the new code to update to v2.1 format the UAF and input variables. This set of runs will be the only set using the file converter. Next runs will start with the v2 formats.
	Base Year: 2011	
	Future Years: 2017, 2018, 2019, 2020, 2023, 2025, 2030 (in nomenclature of files, XX denotes year, example 17 = 2017)	Note that years 2020-2030 have both ref and opt runs. Ref indicates all inputs are based on state supplied data. Opt indicates that state supplied data was augmented with MD optimization control strategy, and OK supplied unit-specific data solely for optimization runs.
camd_hourly_base.csv	Hourly CAMD CEM data	Same for all years.
ertac_hourly_noncamd.csv	Hourly CEM data replacing data in CAMD	C2.1CONUSv2.7_ertac_nonCAMD_hourly.csv Same for all years
	Added MO unit to correct hourly data that was reported in the wrong units (kW instead of GW)	
ertac_initial_uaf.csv	Unit Availability File	C2.1CONUSv2.7_20XX_ertac_initial_uaf.csv (based on final Sept 2017 documentation file.) Same for all years Files were run through the file converter to create the new code input file, ertac_initial_uaf_v2.csv
ertac_control_emissions.csv	Annual Control File	C2.1CONUSv2.7ref_20XX_ertac_control_emissions.csv, C2.1CONUSv2.7opt_ertac_control_emissions.csv (based on final Sept2017 controls file) Same for all years.
	For 2.7, two control files were used. One is the reference case (ref) that includes only those controls supplied by states. One is an optimized file (opt) that removes certain SCR/SNCR coal fired units and certain OK units since they were moved to the seasonal controls file.	
ertac_seasonal_control_emissions.csv	Seasonal Control File	C2.1CONUSv2.7ref_20XX_ertac_control_emissions.csv (based on final Sept2017 controls file) and C2.1CONUSv2.7opt_20XX_ertac_control_emissions.csv Same for all years. For 2.7, two seasonal control files were used. One is the reference case (ref) that includes only those controls supplied by states. One is an optimized file (opt) that includes state data as well as additional ozone season information for certain SCR/SNCR coal fired units and certain OK units. For the optimized units, only OS NOx rates were reduced. NOx rates in other months were left equivalent to reference case information.
	For 2.7, two seasonal control files were used. One is the reference case (ref) that includes only those controls supplied by states. One is an optimized file (opt) that includes state data as well as additional ozone season information for certain SCR/SNCR coal fired units and certain OK units. For the optimized units, only OS NOx rates were reduced. NOx rates in other months were left equivalent to reference case information.	
ertac_growth_rates.csv	Growth Files	C2.7CONUSv2.7ref_20XX_ertac_growth_rates.csv
	Based on AEO 2017 no CPP rates. Used NYCW and SRVC specific growth rates. NYCW did not have updated values. SRVC provided updated values.	
ertac_input_variables.csv	Input Variables File	C2.7CONUSv2.7ref_20XX_ertac_input_variables.csv Code 1.01 files were run through the file converter to create the Code 2.1 input file called ertac_input_variables_v2.csv
ertac_demand_transfer.csv	Transfers of power between regions, fuel/unit types, into or out of systems from renewables and nuclear, etc	C2.7CONUSv2.7ref_20XX_ertac_demand_transfer.csv. Different for all years.
group_total_listing.csv	Aggregation scheme for multi-state caps	C2.7CONUSv2.7ref_20XX_group_total_listing.csv (same for all years) Updated to include latest CSAPR update values
state_total_listing.csv	Aggregation scheme for state level caps	C2.7CONUSv2.7ref_20XX_state_total_listing.csv (same for all years) Updated to include latest CSAPR update assurance level values.

ERTAC File Name	Description	Run Notes
OVERVIEW	Version: 2.7 Reference	Run by VA DEQ - Doris McLeod Sep 2017.
	Code: 2.1	
	Base Year: 2011	Update to UAF, Controls, and nonCAMD hourly. States feedback deadline: June, 2017.
	Future Years: 2020, 2021, 2023, 2025, 2028, and 2030	
camd_hourly_base.csv	Hourly CAMD CEM data	
ertac_hourly_noncamd.csv	Hourly CEM data replacing data in CAMD	C2.1CONUSv2.7_ertac_nonCAMD_hourly.csv
	Updates include adding one hour of reasonable, minimal data to approximately 44 units that Emily Bull (MDE) identified as missing in output files to allow the tool to process these units fully.	
ertac_initial_uaf.csv	Unit Availability File (XX denotes year, example 17 = 2017)	C2.1CONUS2.7_20XX_ertac_initial_uaf.csv: Updates include state inputs and regional boundaries for MROS.
ertac_control_emissions.csv	Annual Control File (XX denotes year, example 17 = 2017)	CONUSv2.7ref_20XX_05052016_ertac_control_emissions.csv
ertac_seasonal_control_emissions.csv	Seasonal Control File (XX denotes year, example 17 = 2017)	C2.1CONUSv2.7_20XX_ertac_seasonal_control_emissions.csv
	Seasonal controls provided by VA, GA, PA (Brunner Island Units 1, 2 & 3 have lower NOX and SO2 rates during the ozone season to represent NG firing.) and MD & NJ	
ertac_growth_rates.csv	Growth Files (XX denotes year, example 17 = 2017)	CONUSv2.7ref_20XX_05052016_ertac_growth_rates.csv
	ANNUAL GROWTH rates spreadsheet supplied by T. Shanley of MI DEQ called AEO2017 GRs.xlsx. Adjustments to	
		SRVC - Peak and annual growth rates supplied by NC for SC, NC, VA and WV.
		NYCW - GRs supplied by NY in memo to MARAMA.
	PEAK GROWTH Rate spreadsheet supplied by T. Shanley (MI) called Gas_Adj_AEO2014_NERC2013 Growth Rates v4	
		SRGW peak growth rate for oil was set to 2.0 to ameliorate an extremely high peak rate, per LADCO.
		SRSE peak GRs and transition hours adjusted for Coal, CC, SC, BG as in Lopez (MI) email to Byeong Kim (GA) 7/20/2017 with subject "SRSE Peak Growth Rate Adjustments"
		COMBINED CYLE GAS: Ameleoration of GDUs created solely for Peak hour demand deficits
		RFCM, MROZ, and MROW combined cycle peak growth rate set to 1.3 and transition hours peak->formula set to 200; formula-> nonpeak set to 2000 based on LADCO, WI, and MI input. All other transition hours remain at default levels.
		CAMX, ; NWPP; RFWZ; SRCE; SRGW Combined cycle gas peak 2028 GR set to 1.3 and transition hours set to 200 and 2000.
	EMM to NERC Crosswalk	SPPR – Two AEO regions, SPPN and SPPS, were aggregated for the coal fuel type only.
ertac_input_variables.csv	Input Variables File (XX denotes year, example 17 = 2017)	C2.1CONUSv2.7_20XX_ertac_input_variables.csv
group_total_listing.csv	Aggregation scheme for multi-state caps (XX denotes year, example 17 = 2017)	C2.1CONUSv2.7_20XX_group_total_listing.csv
state_total_listing.csv	Aggregation scheme for state level caps (XX denotes year, example 17 = 2017)	C2.1CONUSv2.7_20XX_state_total_listing.csv

MINNESOTA POLLUTION CONTROL AGENCY

Attachment 3:

Public notice

Minnesota Pollution Control Agency
Environmental Analysis and Outcomes Division
Public Notice on State Implementation Plan Revision

NOTICE IS HEREBY GIVEN that the Commissioner of the Minnesota Pollution Control Agency (MPCA) has determined that a State Implementation Plan (SIP) revision must be submitted to meet Minnesota's requirements under sections 110(a)(1), 110(a)(2), and 128 of the Clean Air Act (the Act). The draft SIP revision is now available for public comment.

Background. Sections 110(a)(1) and 110(a)(2) of the Act require that states prepare and submit to the U. S. Environmental Protection Agency (EPA) an "infrastructure" SIP within three years of the EPA's issuance of a new National Ambient Air Quality Standard (NAAQS) to demonstrate their continued ability to implement, maintain, and enforce the revised standards. This infrastructure SIP submission addresses the 2015 ozone NAAQS.

Purpose of the SIP revision. The purpose of this SIP revision is to fulfill Minnesota's responsibility under the Act to demonstrate its ability to implement, maintain, and enforce the revised ozone NAAQS cited above. This includes information about Minnesota's air quality programs such as monitoring, permitting, and modeling. Many of these requirements have already been submitted as part of the SIP.

The MPCA will consider changing the contents of the proposed SIP revision based on comments received during the comment period. Following the end of the comment period, the Commissioner will decide whether to submit the proposed SIP revision to the EPA.

MPCA contact person. The MPCA contact person is Christine Steinwand. Written comments, requests, and petitions should be mailed to: Christine Steinwand, Minnesota Pollution Control Agency, Environmental Analysis and Outcomes Division, 520 Lafayette Road North, St. Paul, Minnesota 55155-4194; telephone: 651-757-2327 or toll free 1-800-657-3864; fax: 651-297-8324; and email: Christine.Steinwand@state.mn.us. TTY users may call the MPCA at TTY 651-252-5332 or 1-800-657-3864.

Availability of SIP. A copy of the proposed SIP revision is available on the MPCA's web site at http://www.pca.state.mn.us/public-notices. A copy of the proposed SIP revision is also available upon request by contacting Christine Steinwand at 651-757-2327 or Christine.Steinwand@state.mn.us, or can be mailed to any interested person upon the MPCA's receipt of a written request. Additional materials relating to the SIP revision are available for inspection by appointment at the MPCA, 520 Lafayette Road North, St. Paul, Minnesota 55155-4194, between the hours of 8:00 a.m. and 4:30 p.m., Monday through Friday. To examine these materials, or for more information, please contact Christine Steinwand. All MPCA offices may be reached by calling 1-800-657-3864.

Public comment period and potential public meeting. The public comment period begins July 9, 2018 and ends on August 10, 2018. Your comments must be in writing and received by Christine Steinwand by 4:30 p.m. on August 10, 2018. Written comments may be submitted to them at the mailing address, facsimile number, or e-mail address listed above.

As this SIP revision does not include any substantive changes to the Minnesota's SIP, a public information meeting will only be held if one is requested by 4:30 p.m. on August 10, 2018. If such a meeting is requested, it will be held on August 16, 2018 from 9:00 a.m. to 11:00 a.m. at the MPCA St. Paul Office, 520 Lafayette Road North, St. Paul, Minnesota 55155-4194. To find out if a public information meeting will be held, please contact Christine Steinwand at 651-757-2327 or Christine.Steinwand@state.mn.us after August 10, 2018 at 4:30 p.m. The public information meeting, if one is requested, will provide information, receive public input, and answer questions about the proposed SIP revision. If the public information meeting is held, additional written comments on the proposed documents will be accepted until 4:30pm on August 24, 2018, following the same guidelines described above.

MINNESOTA POLLUTION CONTROL AGENCY

Attachment 4:

Completeness review

Attachment 4: Completeness Review

Contents

A. Administrative Materials (40 CFR pt. 51, Appendix V, Part 2.1)

The EPA's Criteria for Determining the Completeness of Plan Submittals, published at 40 CFR part 51, Appendix V, requires states to provide the basic documents that show that the State has properly followed the administrative requirements called for by the CAA for the adoption of SIPs. The requirements, and how this SIP revision complies with these requirements, are discussed here:

1) Formal Letter of Submittal:

> "A formal letter of submittal from the Governor or his designee, requesting EPA approval of the plan or revision thereof."

Attached to this SIP revision request is a formal letter of submittal from the MPCA Commissioner, John Linc Stine, to the EPA Region V Administrator, Cathy Stepp. The office of the Commissioner of the MPCA is statutorily created in Minnesota Statute § 116.03, subd. 1 (a). The Commissioner is appointed by the Governor, and the duties of the position include acting as the state agent to "apply for, receive, and disburse federal funds made available to the state by federal law or rule and regulations promulgated thereunder for any purpose related to the power and duties of the MPCA or the Commissioner. The Commissioner shall comply with any and all requirements of such federal law or such rules and regulations promulgated thereunder to facilitate application for, receipt, and disbursement of such funds." Minn. Stat. § 116.03 subd. 3.

2) Evidence of State Adoption of Plan and Issuance of Orders in Final Form:

> "Evidence that the State has adopted the plan in the State code or body of regulations; or issued the permit, order, consent agreement (hereafter 'document') in final form. That evidence shall include the date of adoption or final issuance as well as the effective date of the plan, if different from the adoption/issuance date."

The rules and statutes documented in this submittal have previously been incorporated into Minnesota's SIP, and/or approved under the auspices of an iSIP [Sections 110(a)(1) and 110(a)(2) of the Clean Air Act].

3) Legal Authority Documentation:

> "Evidence that the State has the necessary legal authority under State law to adopt and implement the plan."

This SIP submittal documents the MPCA's legal authority in addressing the requirements of Section 110(a)(1) of the Clean Air Act.

4) Compliance with State Procedures:

> "Evidence that the state followed all of the procedural requirements of the State's laws and constitution in conducting and completing the adoption/issuance of the plan."

MPCA complied with all relevant state procedures for issuing the permit as well as the SIP revision.

5) Public Notice:

> "Evidence that public notice was given of the proposed change consistent with the procedures approved by the EPA, including the date of the publication of the notice."

The public notice for the SIP revision was published in the State Register on July 9, 2018 with the public comment period commencing on July 9, 2018 and ending on August 10, 2018. During the public comment period, a copy of the SIP revision was made available at the MPCA office located in St. Paul and on the MPCA's website. A copy of the public notice is attached (Attachment 3).

6) Public Hearing Certification:

> "Certification that public hearing(s) were held in accordance with the information provided in the public notice and the State's laws and constitution, if applicable."

The public notice states: "As this SIP revision does not include any substantive changes to the Minnesota's SIP, a public information meeting will only be held if one is requested by 4:30 p.m. on August 10, 2018. If such a meeting is requested, it will be held on August 16, 2018 from 9:00 a.m. to 11:00 a.m. at the MPCA St. Paul Office, 520 Lafayette

Road North, St. Paul, Minnesota 55155-4194. To find out if a public information meeting will be held, please contact Christine Steinwand at 651-757-2327 or Christine.Steinwand@state.mn.us after August 10, 2018 at 4:30 p.m. The public information meeting, if one is requested, will provide information, receive public input, and answer questions about the proposed SIP revision. If the public information meeting is held, additional written comments on the proposed documents will be accepted until 4:30pm on August 24, 2018, following the same guidelines described above."

[This section will be completed after the comment period ends to reflect whether or not a public hearing was requested and/or held.]

7) Public Comments and State Response:

> "Compilation of the public comments and State's response thereto."

[This section will be completed after the comment period ends to reflect what, if any, comments were received.]

B. Technical Support

1) Pollutants Regulated:

> "Identification of all regulated pollutants affect by the plan."

This infrastructure SIP submission addresses the 2015 ozone NAAQS.

2) Source Identification:

> "Identification of the locations of affected sources including the EPA attainment/nonattainment designation of the locations and the state of the Attainment Plan for the affected area(s)."

Does not apply to this SIP submittal.

3) Emissions Quantification:

> "Quantification of the changes in the plan; allowable emissions from the affected sources; estimates of changes in current actual emissions from affected sources or, where appropriate, quantification of the changes in actual emissions through calculations of the differences between certain baseline levels and allowable emissions anticipated as a result of the revision."

Does not apply to this SIP submittal.

4) NAAQS Protections:

> "The State's demonstration that the NAAQS, prevention of significant deterioration increments, reasonable further progress demonstration, and visibility, as applicable, are protected if the plan is approved and implemented."

The purpose of this SIP submittal is to demonstrate Minnesota's ability to implement, maintain, and enforce the revised NAAQS.

5) Modeling Information:

> "Modeling information required to support the proposed revision, including input data, output data, models used, justification of the model selections, ambient monitoring data used, meteorological data used, justification for use of off-site data (where used), modes of models used, assumptions, and other information relevant to the determination of adequacy of the modeling analysis."

Does not apply to this SIP submittal.

6) Continuous Emission Reduction:

> "Evidence, where necessary, that emission limitations are based on continuous emission reduction technology."

Does not apply to this SIP submittal.

7) Emission Level Assurance:

> "Evidence that the plan contains emission limitations, work practice standards and recordkeeping/requirements, where necessary, to ensure emissions levels."

The purpose of this SIP submittal is to demonstrate Minnesota's ability to implement, maintain, and enforce the revised NAAQS.

8) Compliance/Enforcement:

> "Compliance and enforcement strategies, including how compliance will be determined in practice."

The purpose of this SIP submittal is to demonstrate Minnesota's ability to implement, maintain, and enforce the revised NAAQS.

9) Special Economic and Technological Justifications:

> "Special economic and technological justifications required by any applicable EPA policies, or an explanation of why such justifications are not necessary."

Does not apply to this SIP submittal.

A. Objective

The objective of this document is for Alpine Geophysics, LLC ("Alpine") to report our determination whether there are discrepancies in EPA's air quality modeling, significant contribution calculations, or allocation of allowances to emission units in upwind states linked to the Alsip Village Garage monitor (170310001) in Cook County, Illinois, the lone monitor that links Minnesota to Good Neighbor Rule obligations, and whether EPA's methods have more widespread errors that indicate a problem with these elements as applied to Minnesota.

For Minnesota, we would expect the photochemical grid modeled (PGM) emissions to be reasonably close to historic CEMS emissions because EPA is not modeling significant emission reductions. If the PGM emission input values are significantly higher, EPA may be mischaracterizing an attaining monitor as "maintenance only." We would also expect that the budgeted emissions for the trading program would be reasonably close to historic facility-level emission monitoring data and the PGM emission input values. To the extent these values are not reasonably close, it is an indication that EPA's use of different datasets is not neutral as applied to Minnesota.

As part of this analysis, Alpine compared electric generating units (EGUs) from Indiana, Michigan, Minnesota, Texas, and Wisconsin used in EPA's air quality modeling and to those in EPA's budget allocation determinations. Alpine notes that four separate data files are used in various areas of the analyses supporting the FIP and in this document we directly compare two of these files. Alpine has identified when sources are in one of the data files and not the other or when major discrepancies exist between the two.

B. Background

In developing the air quality improvements associated with proposed EGU and non-EGU controls of the final ozone transport FIP rule, EPA used multiple, sometimes inconsistent, data because it was convenient and readily available.

EPA started by calculating an ozone change factor between two 2026 future year simulations from the proposed ozone transport FIP rule (version 2 platform[1] – **first data set**). These two simulations differ in the fact that NOx emissions are reduced by 30% for both EGU and non-EGU sources in all states in the second non-base case simulation. The change in ozone concentration

[1] EPA-HQ-OAR-2021-0668-0064

at each downwind receptor divided by the change in upwind NOx emissions from the EGU and non-EGU point sources determined the ratio, or calibration, used by EPA[2]. From a Minnesota specific perspective, not only is Minnesota not linked to any monitor in EPA's 2026 base case calculations and by which the calibration factors are estimated, Minnesota is also not required to control emissions from any non-EGU sources in 2026. In addition, this 2026v2 platform also improperly characterizes emissions from Minnesota EGU sources that are fully expected to operate in 2026. EPA's emission EGU projection with the Integrated Planning Model (IPM) chose to zero out emissions from these units thereby removing their potential reduction impact from the calibration calculation. As a result, it is probable that the reactivity included in the calibration factor is compromised because all expected emissions from the state are not adequately characterized in the factor.

To apply these calibration factors to determine the impact of emission reductions on base case ozone concentrations, EPA utilized a **second set** of data from the final rule (version 3 modeling platform)[3]. Note that this updated platform, in addition to including alternate anthropogenic emissions from many states and categories, also utilized alternate boundary condition emissions (e.g., international transport), updated biogenic emissions estimates, and included NOx emissions from lightning strikes; all elements that EPA attempts to neutralize the differences by using more calibration factor adjustments. The 2023 base case projection from this version 3 was used to identify future year nonattainment or maintenance monitors, significant contribution values from each upwind state to downwind receptors, and to select the top modeled days that are used in the change in concentration/change in emissions calibration calculations. As noted above, while the 2026v2 calibration calculation did not contain properly characterized emissions from various Minnesota EGU sources, the 2023v3, and associated design values, significant contribution metrics, and top modeled days do contain these sources.

To develop the estimated emission reductions associated with the various control options proposed by EPA, the agency used yet a **third set** of EGU data[4], historical CEM-reported heat input (a.k.a., Engineering Analytics or EA), emission rates, and calculated emissions from 2017-2021. This third set of emissions differs again from both the first and second sets in the fact that IPM was not used to forecast emissions beyond current years. From this third set, and another 2023 forecast, the impact of emission rates was calculated and emission differences between a base simulation and controlled simulation was calculated. Again, it is important to note that units presumed to be in operation in this third set of projections were estimated with alternate

[2] EPA-HQ-OAR-2021-0668-1080
[3] EPA-HQ-OAR-2021-0668-1000
[4] Appx. A, EPA-HQ-OAR-2021-0668-1080

emission projections to either the v2 or v3 projections from IPM, used in the calibration calculation and the final rule attainment designation process. The emissions budgets assigned to sources with this EA data calculation were then used to estimate the air quality impact of the final rule.

When EPA eventually puts the pieces together, these seemingly incongruous factors are applied to each other. The emissions delta from the **third set** of data is scaled to a change in ozone/ton of NOx reduced using the calibration factor from the **first set of data** and then applied to the ozone concentrations and emissions included in the **second set** of data. The resulting concentration values, while seemingly directionally consistent with the anticipated change in emissions, are unverified using an independent photochemical model run (EPA's preferred method[5]) and instead are corroborated by EPA utilizing yet another calibration simulation[6].

Finally, a **fourth set of data[7]** was used to estimate the costs associated with the optimization of SCR and SNCR control on units which already have these post-combustion controls installed. Using parameters from an October 2021 version of IPM's NEEDS input file (held constant from the proposed rule), unit specific characteristics were used to evaluate costs from this optimization step. Of note, costs for units optimized in Minnesota are estimated to have cost per ton values higher than the final FIP range of accepted values.

C. Specific Comparison in this Document

The EPA projected 2023 and 2026 baseline EGU emissions using version 6—Updated Summer 2021 Reference Case of the Integrated Planning Model (IPM)[8]. IPM is described by EPA as a state-of-the-art, peer-reviewed, multi-regional, dynamic, deterministic linear programming model of the contiguous U.S. electric power sector. It provides forecasts of least cost capacity expansion, electricity dispatch, and emissions control strategies while meeting energy demand and environmental, transmission, dispatch, and reliability constraints.

Additionally, 2023 through 2026 EGU emissions baseline levels were developed through engineering analytics as an alternative approach that did not involve IPM. The EPA developed this inventory for use in determining emission reduction potential and corresponding state-level emissions budgets.

[7] EPA-HQ-OAR-2021-0668-0996
[8] https://www.epa.gov/power-sector-modeling

EPA has articulated[9] a ''4-step framework'' within which to assess interstate transport obligations for ozone. In the FIP rule to address interstate transport obligations for the 2015 ozone NAAQS, the EPA is again utilizing the 4-step interstate transport framework. These steps are:

(1) identifying downwind receptors that are expected to have problems attaining the NAAQS (nonattainment receptors) or maintaining the NAAQS (maintenance receptors);
(2) determining which upwind states are ''linked'' to these identified downwind receptors based on a numerical contribution threshold;
(3) for states linked to downwind air quality problems, identifying upwind emissions on a statewide basis that significantly contribute to downwind nonattainment or interfere with downwind maintenance of the NAAQS, considering cost- and air quality-based factors; and
(4) for upwind states that are found to have emissions that significantly contribute to nonattainment or interfere with maintenance of the NAAQS in any downwind state, implementing the necessary emissions reductions through enforceable measures.

By using IPM at Step 1 and 2, EPA indicates it is selecting the more conservative approach for identifying the degree of nonattainment and geography of states contributing above 1 percent. By using Engineering Analytics at Step 3, EPA indicates that it is selecting the more conservative value to codify into state-level budgets.[10]

EPA explains in the final rule preamble why these techniques are considered appropriate for the purposes at each step of the analysis, and why they are not incompatible, nor do they produce results so different as to call into question their reliability or the bases for EPA's regulatory determinations. EPA states that the nationwide projected ozone season total NOx emissions vary by less than 1 percent in the 2023 analytic year, however, EPA is silent as to a comparison of important sub-regional and unit emission rates, including differences detailed in this document that demonstrate variance of significantly greater than 1 percent for the emission rates relevant to Minnesota.

D. Review of Data Used by U.S. EPA

1. EPA's 2016v3 Modeling Platform Inventories

[9] See CSAPR, Final Rule, 76 FR 48208, 48248– 48249 (August 8, 2011); CSAPR Update, Final Rule, 81 FR 74504, 74517–74521 (October 26, 2016).
[10] 88 FR 36700

The EPA used version 3 of the 2016-based air quality modeling platform[11] (i.e., 2016v3) to provide the foundational model-input data sets for 2016, 2023, and 2026.

The 2023 and 2026 electric generating unit (EGU) emissions inventories from the FIP modeling platform used the outputs of the EPA's Updated Summer 2021 Reference Case of the Integrated Planning Model (IPM). [12] The projections are calculated using the ratio of the analytic year seasonal generation in the IPM parsed file and the base year seasonal generation at each unit for each fuel type in the unit as derived from the 2018 EIA-923 tables and the 2018 NEI. New controls identified at a unit in the IPM parsed file are accounted for with appropriate emissions reductions as estimated by the model using cost-minimization functions. Both environmental and economic compliance rules placed on these units are based on future year scenarios configured by EPA.

IPM generates EGU emissions using data from continuous emissions monitoring systems (CEMS) and other monitoring systems allowed for use by qualifying units under 40 CFR part 75, with other EGU pollutants estimated using emissions factors and annual heat input data reported to the EPA. For EGUs not reporting under Part 75, the EPA used data submitted to the NEI by the state, local, and tribal agencies.

Throughout all of the CSAPR rules to date, and prior interstate transport actions, the EPA has used IPM at Steps 1 and 2 as they state it is best suited for projecting emissions in an airshed, projecting emissions for time horizons more than a few years out (for which changes would not yet be announced and thus projecting changes is critical), and for scenarios where the assumed change in emissions is not being codified into a state emissions reduction requirement.

The agency notes that using IPM at Steps 1 and 2 helps the EPA avoid overstating the current analytic year receptor values (Step 1) and future year linkages (Step 2) by reflecting reductions anticipated to occur within the airshed in the relevant timeframe.

2. EPA's Engineering Analytics Inventory

Additional 2023 through 2026 EGU emissions baseline levels were developed by EPA through Engineering Analytics (EA) as an alternative approach that did not involve IPM[13]. The EPA developed this inventory for use in Step 3 of this final rule, where it determined emissions reduction potential and corresponding state-level emissions budgets.

[11] EPA-HQ-OAR-2021-0668-1000
[12] 88 FR 36699
[13] Id

EPA adopted a similar approach to the CSAPR Update[14] and the Revised CSAPR Update[15] where it utilized historical data and an engineering analytics approach in Step 3. EPA justified this approach stating it was to avoid overstating optimization and dispatch decisions in state-emissions budget quantification that may not be possible in a short time frame. The EPA did this by starting with unit-level reported data and only making adjustments to reflect known baseline changes such as planned retirements and new builds (for the base case scenarios) and also identified mitigation strategies for determining state emissions budgets.

According to EPA, engineering analytics has been a useful tool for Step 3 state-level emissions reduction estimates in CSAPR rulemaking, because at that step the EPA is dealing with more geographic granularity (state-level as opposed to regional air shed), more near-term (as opposed to medium-term) assessments, and scenarios where reduction estimates are codified into regulatory requirements. EPA states that using the Engineering Analytics tool at this step ensures that the EPA is not codifying into the base case, and consequently into state emissions budgets, changes in the power sector that are merely modeled to occur rather than announced by real world actors.

Under the final rule, the determination of whether a unit is eligible to receive allocations as an “existing” unit or as a “new” unit varies across control periods. For the control periods in 2023 through 2025, a unit in a covered state meeting the CSAPR applicability criteria is treated as eligible to receive an allocation as an existing unit if the unit’s emissions were considered in the process for determining the state’s emissions budget for the respective control period in the final rule. Thus, if the unit was subject to requirements to report emissions and heat input under 40 CFR part 75 for the entire ozone season from May 1, 2021, through September 30, 2021, and reported any heat input greater than zero during that period, the unit is generally treated as eligible to receive an allocation as an existing unit for the control periods in 2023 through 2025.

For the existing units identified through the process detailed above, allocations for each control period are calculated using heat input and NOx emissions reported under either the CSAPR trading programs or the Acid Rain Program for a 5-year historical baseline period. To calculate allocations for the control periods in 2023 through 2025 in the final rule, EPA is using data reported for the control periods from 2017 through 2021. In each control period, the quantity of allowances allocated to existing units in a state using this methodology will be the portion of the state’s emissions budget remaining after subtraction of the new unit set-aside for the control period.

E. Comparison and Issues

We compared EPA's IPM-generated EGU ozone season NOx emission projections with matched EGU units from the Engineering Analytics projections for CEM sources in Indiana, Michigan, Minnesota, Texas, and Wisconsin to determine if inconsistencies existed in how EPA developed emission projections for purposes of its Step 1, 2 and 3 of the transport frameworks.

EPA's IPM-generated emission estimates were obtained from the 2023 ozone season modeling platform files associated with the FIP air quality modeling analyses[16,17].

EA-generated emission estimates and budget allocation values were obtained from EPA-published spreadsheets found in the FIP docket[18].

What we found was that for many units, historical heat input/CEM-based emissions between 2017 and 2021 are significantly lower than those projected by EPA in 2023 (now a near term projection) and that were used to develop design value and significant contribution metrics.

Within each reviewed upwind state potentially affecting the Alsip/Village Garage Monitor, we investigated the top modeled units and the top emission allocated units for discrepancies between the two data platforms. Results for each are provided in the tables and graphs below.

Indiana

IPM projected emissions from the top 2023 base case unit (Clifty Creek Unit 6) in Indiana is almost 5.5 times higher than the maximum year monitored emissions reported between 2017-2021. Table 1 presents this information for this unit as well as similar information for the other highest IPM generated emission units in the state. The top 3 units with IPM-generated emissions are collectively almost 55% higher than the maximum average NOx emissions rate reported from 2017-2021.

The next three highest units presented in Table 1 are collectively 55% lower than the maximum CEM NOx emissions rate reported for the 2017-2021 period.

Figure 1 through Figure 7 present this information for multiple units listed in Table 1. Blue dots represent the historical ozone season NOx emissions from CEM-reported data (orange dot represents 2016 CEM also modeled by EPA), orange triangles represent the 2023 and 2026 IPM

Michigan

IPM projected emissions from the top 2023 base case units in Michigan are collectively 3.1 times higher than the maximum year monitored emissions reported between 2017-2021 for these same units. Table 2 presents this information for these units in the state. The top 3 units with IPM-generated emissions are collectively 3.6 times higher than the maximum average NOx emissions rate reported from 2017-2021 for these same sources and of these three, the top two were given no budget allocation in 2023 using the EA method as these units are identified as retired in 2023.

Figure 8 through Figure 14 present this information for multiple units listed in Table 2. Blue dots represent the historical ozone season NOx emissions from CEM-reported data (orange dot represents 2016 CEM also modeled by EPA), orange triangles represent the 2023 and 2026 IPM base case projected emissions, and grey diamonds represent the FIP published allowance allocations.

Minnesota

IPM projected emissions from the top seven units in Minnesota, that make up 99% of the ozone season NOx emissions in the portion of the 2023 projection comprised from CEM-reporting sources and ultimately assigned allocations in Step 3, are in aggregate 20% higher than the maximum year monitored emissions reported between 2017-2021. Table 3 presents this information for these seven units.

As the most extreme example, EPA's IPM-modeled ozone season NOx emissions in the 2023 base case were 3.6 times greater in magnitude at the Hibbard Energy Center, unit 4, than the maximum historical ozone season emissions from the 2017 – 2021 period.

Figure 15 through Figure 21 present this information for each of the units listed in Table 3. Blue dots represent the historical ozone season NOx emissions from CEM-reported data (orange dot represents 2016 CEM also modeled by EPA), orange triangles represent the 2023 and 2026 IPM base case projected emissions, and grey diamonds represent the FIP published allowance allocations.

Except for Boswell Unit 4 (Figure 3), all represented units have IPM-modeled 2023 ozone season NOx emissions exceeding the maximum historical CEM-based NOx emissions from 2017-2021 (i.e., orange triangles are higher than blue circles).

Wisconsin

IPM projected emissions from the top 2023 base case units in Wisconsin are collectively 4% times lower than the maximum year monitored emissions reported between 2017-2021 for these same units. Table 5 presents this information for these units in the state.

Figure 29 through Figure 35 present this information for multiple units listed in Table 5. Historical CEM-based ozone season NOx emissions, EPA's EA-based allowance allocation, EPA's IPM generated 2023 emissions, and percentage comparison for top 2023 modeled Wisconsin units.. Blue dots represent the historical ozone season NOx emissions from CEM-reported data (orange dot represents 2016 CEM also modeled by EPA), orange triangles represent the 2023 and 2026 IPM base case projected emissions, and grey diamonds represent the FIP published allowance allocations.

F. Observations

EPA failed to appropriately estimate 2023 base case emissions for multiple upwind EGU sources using IPM thereby compromising downwind concentrations and significant contribution calculations associated with these states. The agency should have used consistent data in each step of the process to ensure that calculations conducted were relevant to each other and provided certainty in direction and value. If EPA had properly characterized emissions at these facilities using historical operation trends (as it did in the Step 3 process), the Alsip monitor in Cook County, Illinois, with which Minnesota is linked, may have modeled in attainment of the 2015 ozone NAAQS, removing Minnesota from the FIP in Step 2 of the transport framework.

It is understood that allocations for these units (Step 3) may be lower because of EPA's estimated optimization of post-combustion controls on some of these sources and new source set aside reduction, yet there is no valid reason for the IPM-generated base case projection of many of these sources to have such significantly higher values for purposes of Step 1 and Step 2 in the transport framework. In our opinion, conservative estimates or not, individual unit-level emission over-estimation and a collective over-estimation of emissions for key units subject to control, potentially only because of this over-estimation, is technically negligent.

Except for presented units in Wisconsin, represented states have the majority of IPM-modeled 2023 ozone season NOx emissions exceeding the maximum historical CEM-based NOx emissions from 2017-2021. As these modeled values were the ozone season NOx emissions used for these sources to represent upwind state contribution to downwind design values and significant contribution calculations, it is safe to deduce that the higher the modeled emission values, the higher the downwind concentrations at receptors like the Alsip monitor in Cook County, Illinois (170310001) and significant contribution calculations from upwind states to that monitor.

Furthermore, if the projected near-term unit-level emissions from IPM were more in line with recent historical CEM-based observations, particularly if the pattern observed at these sources hold for other sources, the projected maximum design value at the Alsip monitor may have been modeled as attainment, breaking the link between Minnesota and the receptor.

Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality Standards; Response to Judicial Stays of SIP Disapproval Action for Certain States

AGENCY: Environmental Protection Agency (EPA).

ACTION: Interim final rule; request for comment.

SUMMARY: The Environmental Protection Agency (EPA) is taking interim final action to stay, for emissions sources in Arkansas, Kentucky, Louisiana, Mississippi, Missouri, and Texas only, the effectiveness of the federal implementation plan (FIP) requirements established to address the obligations of these and other states to mitigate interstate air pollution with respect to the 2015 national ambient air quality standards (NAAQS) for ozone (the Good Neighbor Plan). The EPA is also revising certain other regulations to ensure that sources in these states will continue to be subject to previously established requirements to mitigate interstate air pollution with respect to other ozone NAAQS while the Good Neighbor Plan's requirements are stayed. These revisions will also ensure that the stay is limited to requirements for which the EPA does not currently have authority to implement a FIP pending judicial review. The stay and the associated revisions to other regulations are being issued in response to judicial orders that partially stay, pending judicial review, a separate, earlier EPA action which disapproved certain state implementation plan (SIP) revisions submitted by these and other states. Finally, for states for which the Good Neighbor Plan's requirements are not being stayed, the EPA is revising three near-term deadlines that are incorrect as published in the Good Neighbor Plan.

DATES: This interim final rule is effective on August 4, 2023. Comments on this rule must be received on or before August 30, 2023.

ADDRESSES: You may send comments, identified by Docket ID No. EPA–HQ–OAR–2021–0668, by any of the following methods:

- *Federal eRulemaking portal: https://www.regulations.gov* (our preferred method). Follow the online instructions for submitting comments.
- *Mail:* U.S. Environmental Protection Agency, EPA Docket Center, Air and Radiation Docket, Mail Code 28221T, 1200 Pennsylvania Avenue NW, Washington, DC 20460.
- *Hand delivery or courier:* EPA Docket Center, WJC West Building, Room 3334, 1301 Constitution Avenue NW, Washington, DC 20004. The Docket Center's hours of operations are 8:30 a.m.–4:30 p.m., Monday–Friday (except federal holidays).

Comments received may be posted without change to *https://www.regulations.gov,* including any personal information provided. For detailed instructions on sending comments, see the "Public Participation" heading of the **SUPPLEMENTARY INFORMATION** section of this document.

FOR FURTHER INFORMATION CONTACT: David Lifland, Clean Air Markets Division, Office of Atmospheric Protection, Office of Air and Radiation, U.S. Environmental Protection Agency, Mail Code 6204A, 1200 Pennsylvania Avenue NW, Washington, DC 20460; telephone: 202–343–9151; email: *lifland.david@epa.gov.*

SUPPLEMENTARY INFORMATION:

I. General

A. Public Participation

Submit your written comments, identified by Docket ID No. EPA–HQ–OAR–2021–0668, at *https://www.regulations.gov* (our preferred method), or by the other methods identified in the **ADDRESSES** section. Once submitted, comments cannot be edited or removed from the docket. The EPA may publish any comment received to its public docket. Do not submit to the EPA's docket at *https://www.regulations.gov* any information you consider to be Confidential Business Information (CBI), Proprietary Business Information (PBI), or other information whose disclosure is restricted by statute. Multimedia submissions (audio, video, etc.) must be accompanied by a written comment. The written comment is considered the official comment and should include discussion of all points you wish to make. The EPA will generally not consider comments or comment contents located outside of the primary submission (*i.e.,* on the web, cloud, or other file sharing system). Please visit *https://www.epa.gov/dockets/commenting-epa-dockets* for additional submission methods; the full EPA public comment policy; information about CBI, PBI, or multimedia submissions; and general guidance on making effective comments.

B. Potentially Affected Entities

This action revises on an interim basis the Good Neighbor Plan, which applies to electricity generating units (EGUs) and non-EGU industrial sources. This action also revises other allowance trading program regulations that apply to EGUs but not to non-EGU industrial sources. The affected emissions sources are generally in the following industry groups:

Industry group	North American Industry Classification System (NAICS) code
Fossil Fuel Electric Power Generation	221112
Pipeline Transportation of Natural Gas	4862
Cement and Concrete Product Manufacturing	3273
Iron and Steel Mills and Ferroalloy Manufacturing	3311
Glass and Glass Product Manufacturing	3272
Basic Chemical Manufacturing	3251
Petroleum and Coal Products Manufacturing	3241
Pulp, Paper, and Paperboard Mills	3221
Metal Ore Mining	2122
Solid Waste Combustors and Incinerators	562213

The Good Neighbor Plan applies to emissions sources in Alabama, Arkansas, California, Illinois, Indiana, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Texas, Utah, Virginia, West Virginia, and Wisconsin. The portions of this action staying the Good Neighbor Plan's requirements and revising other allowance trading program regulations apply to sources in Arkansas, Kentucky, Louisiana, Mississippi, Missouri, and Texas. The portions of this action revising certain near-term deadlines under the Good Neighbor Plan apply to emissions sources in the other listed states, for which the Good Neighbor Plan's requirements are not being stayed.

The information provided in this section on potentially affected entities is not intended to be exhaustive. If you have questions regarding the applicability of this action to a particular entity, consult the person listed in the **FOR FURTHER INFORMATION CONTACT** section.

C. Statutory Authority

Statutory authority to issue the amendments finalized in this action is provided by the same Clean Air Act (CAA) provisions that provided authority to issue the regulations being amended: CAA section 110(a) and (c), 42 U.S.C. 7410(a) and (c) (SIP and FIP requirements, including requirements for mitigation of interstate air pollution), and CAA section 301, 42 U.S.C. 7601 (general rulemaking authority). Statutory authority for the rulemaking procedures followed in this action is provided by Administrative Procedure Act (APA) section 553, 5 U.S.C. 553.

II. Regulatory Revisions

A. Response to Stay Orders

1. Background and Summary

CAA section 110(a)(2)(D)(i)(I), also known as the ''good neighbor'' provision, requires each state's SIP to include provisions sufficient to ''prohibit[ ], consistent with the provisions of this subchapter, any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will—(I) contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any [NAAQS].'' The EPA often refers to the emissions reduction requirements under this provision as ''good neighbor obligations'' and submissions addressing these requirements as ''good neighbor SIPs.''

CAA section 110(c)(1) requires the EPA Administrator to promulgate a FIP at any time within two years after the Administrator: (i) finds that a state has failed to make a required SIP submission; (ii) finds a SIP submission to be incomplete pursuant to CAA section 110(k)(1)(C); or (iii) disapproves a SIP submission. This obligation applies unless the state corrects the deficiency through a SIP revision that the Administrator approves before the FIP is promulgated.

On February 13, 2023, the EPA published a final action fully or partially disapproving good neighbor SIPs submitted by 21 states with respect to the 2015 ozone NAAQS (the SIP Disapproval action).[1] Consistent with the requirements of CAA section 110(c)(1), following the SIP Disapproval action, on March 15, 2023, the EPA Administrator signed a separate final action promulgating a FIP, which is referred to here as the ''Good Neighbor Plan'' or the ''Rule.''[2] The Good Neighbor Plan requires EGUs and non-EGU industrial sources in the 21 states whose good neighbor SIPs the EPA had disapproved in the SIP Disapproval action (as well as two other states for which the EPA had previously made findings of failure to submit good neighbor SIPs) to reduce their emissions of nitrogen oxides (NO_X) during the May-September ''ozone season'' to address the states' good neighbor obligations with respect to the 2015 ozone NAAQS.[3] The Good Neighbor Plan was published in the **Federal Register** on June 5, 2023, and its requirements will be phased in over several years starting on the Rule's August 4, 2023, effective date.

To implement the required emissions reductions from EGUs, the Good Neighbor Plan uses an emissions allowance trading program. The EPA has previously established three successive allowance trading programs for EGUs' seasonal NO_X emissions to address states' good neighbor obligations with respect to the 1997 and 2008 ozone NAAQS—referred to here as the CSAPR NO_X Ozone Season ''Group 1,'' ''Group 2,'' and ''Group 3'' trading programs—in the Cross-State Air Pollution Rule (CSAPR),[4] the CSAPR Update,[5] and the Revised CSAPR Update,[6] respectively. The Good Neighbor Plan does not establish a new emissions trading program, but instead modifies the Group 3 trading program initially established in the Revised CSAPR Update and expands the program to apply to EGUs in the additional states included in the Good Neighbor Plan.

In each of the successive rulemakings to address good neighbor obligations with respect to an ozone NAAQS, the EPA has coordinated compliance requirements by allowing the participation of a state's EGUs in the most recent seasonal NO_X trading program to also satisfy any requirements to participate in a previous seasonal NO_X trading program established to address the state's good neighbor obligations with respect to a less protective NAAQS.[7] Because of the EPA's coordination efforts, for 19 of the states covered by the Good Neighbor Plan as signed, including Arkansas, Kentucky, Louisiana, Mississippi, Missouri, and Texas, participation of the state's EGUs in the Group 3 trading program not only serves as the mechanism for partially addressing the states' good neighbor obligations with respect to the 2015 ozone NAAQS, but also serves as the mechanism for addressing the states' good neighbor obligations with respect to the 2008 ozone NAAQS.[8] For eight of the states, including Arkansas, Kentucky, Louisiana, Mississippi, and Missouri, participation of the states' EGUs in the Group 3 trading program serves as the mechanism for addressing the states' good neighbor obligations with respect to the 1997 ozone NAAQS as well.[9]

Petitioners challenging the SIP Disapproval action have filed motions in several courts for partial stays of that action with respect to the SIPs submitted by particular states. Subsequent to the Good Neighbor Plan's signature date, courts have granted some of these motions. On May 1 and June 8, 2023, the U.S. Court of Appeals for the Fifth Circuit issued orders staying the SIP Disapproval action with respect to Louisiana, Mississippi, and Texas pending judicial review on the merits.[10] On May 25 and 26, 2023, the U.S. Court of Appeals for the Eighth Circuit issued orders staying the SIP Disapproval action with respect to Arkansas and Missouri pending judicial review on the merits.[11] On May 31, 2023, the U.S. Court of Appeals for the Sixth Circuit issued an order administratively staying the SIP Disapproval action with respect

[1] Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 FR 9336 (February 13, 2023).

[2] Federal ''Good Neighbor Plan'' for the 2015 Ozone National Ambient Air Quality Standards, 88 FR 36654 (June 5, 2023).

[3] *See generally id.* The Good Neighbor Plan's requirements for EGUs apply in 22 of the 23 covered states, while the requirements for non-EGU industrial sources apply in 20 of the 23 covered states.

[4] Federal Implementation Plans: Interstate Transport of Fine Particulate Matter and Ozone and Correction of SIP Approvals, 76 FR 48208 (August 8, 2011). CSAPR addressed states' good neighbor obligations with respect to the 1997 ozone NAAQS, as well as the 1997 and 2006 NAAQS for fine particulate matter.

[5] Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS, 81 FR 74504 (October 26, 2016). The CSAPR Update addressed states' good neighbor obligations with respect to the 2008 ozone NAAQS.

[6] Revised Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS, 86 FR 23054 (April 30, 2021). The Revised CSAPR Update readdressed states' good neighbor obligations with respect to the 2008 ozone NAAQS in response to the remand of the CSAPR Update in *Wisconsin* v. *EPA,* 938 F.3d 303 (D.C. Cir. 2019).

[11] Order, *Arkansas* v. *EPA,* No. 23–1320 (8th Cir. May 25, 2023); Order, *Missouri* v. *EPA,* No. 23–1719 (8th Cir. May 26, 2023); Order, *Union Electric Co.* v. *EPA,* No. 23–1751 (8th Cir. May 26, 2023). The orders are available in the docket.

to Kentucky pending review of Kentucky's stay motion.[12]

The EPA's authority under CAA section 110(c)(1) to establish the Good Neighbor Plan's FIP requirements for the sources in a given state is triggered by either the EPA's disapproval of the state's good neighbor SIP with respect to the 2015 ozone NAAQS or the EPA's finding of the state's failure to submit such a SIP. Accordingly, as a result of the orders partially staying the SIP Disapproval action, the EPA must act to ensure that the Good Neighbor Plan's requirements that were issued to address good neighbor obligations with respect to the 2015 ozone NAAQS and that apply to either EGUs or non-EGU industrial sources in each of the states for which a stay order has been issued will not take effect while the stay of the SIP Disapproval action as to that state remains in place. To ensure full compliance with the stay orders, the EPA is also staying these requirements for sources in Indian country located within the borders of a state covered by a stay order, including areas of Indian country not subject to the state's SIP authority.[13] However, as noted earlier in this section, the Group 3 trading program is also the mechanism to implement requirements previously established for EGUs in most of the covered states to address the states' good neighbor obligations with respect to the 2008 ozone NAAQS and, in some cases, the 1997 ozone NAAQS. The SIP Disapproval action was not a basis for the authority relied on by the EPA in the previous rulemakings to establish emissions reduction requirements with respect to the 2008 or 1997 ozone NAAQS, and the stay orders do not affect these pre-existing requirements. The EPA's authority for the rulemakings addressing the 2008 and 1997 ozone NAAQS remains in place. Implementing the stay orders therefore requires the EPA not only to stay the new requirements established for EGUs and non-EGU industrial sources in the Good Neighbor Plan to address their states' good neighbor obligations with respect to the 2015 ozone NAAQS, but also to preserve status quo requirements established in previous rulemakings to address their states' good neighbor obligations with respect to the 2008 and 1997 ozone NAAQS.

Thus, the EPA in this action is revising the Good Neighbor Plan FIP requirements and the regulations for the Group 2 trading program to require the EGUs in each state covered by a stay order for the SIP Disapproval action to participate in the Group 2 trading program instead of the Group 3 trading program while the stay for that state remains in place. A small number of conforming revisions are also being made to the regulations for the Group 1 and Group 3 trading programs. Together, the revisions preserve the status quo by making the trading program requirements that will apply to the EGUs in each state for which the SIP Disapproval action has been stayed substantively identical to the trading program requirements that would have applied to the EGUs in that state if the state had not been covered by the Good Neighbor Plan. The revisions to the trading program regulations are summarized in the remainder of this section and are discussed in detail in section II.A.2 of this document.[14]

First, for EGUs in Arkansas, Mississippi, Missouri, and Texas, which before the Good Neighbor Plan were covered by the Group 2 trading program as promulgated in the CSAPR Update rather than the Group 3 trading program, the revisions in this action restore the state emissions budgets, unit-level allowance allocation provisions, and banked allowance holdings that would have been in effect for the EGUs in these states under the Group 2 trading program in the absence of the Good Neighbor Plan.

Second, for EGUs in Kentucky and Louisiana, which before the Good Neighbor Plan were already covered by the Group 3 trading program as promulgated in the Revised CSAPR Update, the revisions in this action modify the Group 2 and Group 3 trading program regulations so as to establish under the Group 2 trading program the state emissions budgets, unit-level allowance allocation provisions, and banked allowance holdings that would have been in effect for the EGUs in these states under the Group 3 trading program in the absence of the Good Neighbor Plan.

Finally, for EGUs in all states that will now be covered by the Group 2 trading program, the revisions in this action establish two non-interchangeable subtypes of Group 2 allowances: CSAPR NO_X Ozone Season Original Group 2 allowances and CSAPR NO_X Ozone Season Expanded Group 2 allowances.[15] EGUs in Arkansas, Mississippi, Missouri, and Texas, which would have been covered by the Group 2 trading program in the absence of the Good Neighbor Plan, will use Original Group 2 allowances for compliance (as will EGUs in Iowa, Kansas, and Tennessee, which are not covered by the Good Neighbor Plan and remain in the Group 2 trading program). EGUs in Kentucky and Louisiana, which would have been covered by the Group 3 trading program in the absence of the Good Neighbor Plan, will use Expanded Group 2 allowances for compliance. The requirements to use different subtypes of Group 2 allowances will preserve the status quo distinction between these two sets of EGUs that already existed before the Good Neighbor Plan and that continues to exist with the stay of the Good Neighbor Plan as to these states, because the allowances that EGUs in Kentucky and Louisiana have used for compliance under the Group 3 trading program as promulgated in the Revised CSAPR Update are not interchangeable with the allowances that EGUs in the other states have used for compliance under the Group 2 trading program.

The amendments to the regulatory requirements for EGUs and non-EGU industrial sources that the EPA is finalizing in this action in response to the stay orders are being made on an interim basis and will remain in place while the judicial proceedings in which the stay orders were issued remain pending. After the courts have reached final determinations on the merits in those proceedings, the EPA will take further action consistent with the final determinations. At the time of this rulemaking, the EPA cannot predict how the Agency's future action may affect the amendments being finalized in this action.

2. Specific Regulatory Revisions

The regulatory revisions to 40 CFR part 52 that are being adopted in this action to implement the orders staying the SIP Disapproval action for non-EGU industrial sources in Arkansas, Kentucky, Louisiana, Mississippi, Missouri, and Texas and Indian country

[12] Order, *Kentucky* v. *EPA*, No. 23–3216 (6th Cir. May 31, 2023), available in the docket.

[13] For sources in areas of Indian country not subject to the SIP authority of the states within whose borders the areas of Indian country are located, the EPA issued the Good Neighbor Plan's requirements not under authority of CAA section 110(c)(1) but under authority of CAA section 301(d)(4). *See* 88 FR 36690–92. However, because the EPA exercised its authority under CAA section 301(d)(4) only with respect to areas of Indian country within the borders of states for which requirements were being issued under CAA section 110(c)(1), *id.* at 36692, these areas of Indian country are indirectly implicated by the orders partially staying the SIP Disapproval action for the respective states.

[14] The EPA has included documents in the docket that show all the regulatory revisions being adopted in this action in redline-strikeout format.

[15] The non-interchangeability will be automatically enforced through the use of different codes for the two subtypes of Group 2 allowances in the EPA's Allowance Management System, where all allowance allocations, transfers, and deductions under the Group 2 trading program are recorded.

within the borders of those states include the addition of text at § 52.40(c)(4) to stay the effectiveness of the Good Neighbor Plan's requirements for non-EGU industrial sources at §§ 52.41 through 52.46 and the remainder of § 52.40 for states covered by stay orders and the addition of parallel text in the state-specific subparts of part 52 for each of the states.[16]

The regulatory revisions to 40 CFR parts 52 and 97 that are being adopted in this action to implement the orders staying the SIP Disapproval action for EGUs in Arkansas, Kentucky, Louisiana, Mississippi, Missouri, and Texas and Indian country within the borders of those states while ensuring continued implementation of requirements established to address good neighbor obligations under rules promulgated before the Good Neighbor Plan include the following:

- The addition of text at § 52.38(b)(2)(iii)(D) to stay the effectiveness of the Good Neighbor Plan's requirements at § 52.38(b)(2)(iii)(A) and (B) for EGUs to participate in the enhanced Group 3 trading program for control periods after 2022 for states covered by stay orders, the addition of text at § 52.38(b)(2)(ii)(D) to require those EGUs to participate in the Group 2 trading program while that stay remains in place, and the addition of parallel text in the state-specific subparts of part 52 for each of the states.[17]
- The revision of text at § 52.38(b)(16)(ii)(B) to provide for continued administration by the EPA after 2022, for states covered by stay orders, of state Group 2 trading programs integrated with the federal Group 2 trading program under approved SIP revisions.[18]
- The revision and addition of text at § 97.802 to define ''Original'' and ''Expanded'' subtypes of CSAPR NO_X Ozone Season Group 2 allowances, with conforming revisions and additions at §§ 97.502, 97.1002, 97.811(d) and (e), 97.821(e), 97.526(d) and (e), 97.826(d) through (f), and 52.38(b)(14).
- The revision of text at §§ 97.806(c), 97.824(a) and (d), and 97.825(a) to provide for EGUs in states covered by stay orders and covered by the Group 3 trading program before 2023 to use Expanded Group 2 allowances for compliance and for EGUs in other states covered by the Group 2 trading program to use Original Group 2 allowances for compliance, with conforming revisions at § 52.38(b)(14).
- The revision of text at § 97.810(a) and (b) to provide EGUs in states covered by stay orders the same amounts for state emissions budgets, new unit set-asides, Indian country new unit set-asides, and variability limits that would have applied under the Group 2 trading program or the Group 3 trading program, as applicable for the state, in the absence of the Good Neighbor Plan.
- The revision of text at § 97.811(a)(2) and § 97.821(e) to provide EGUs in states covered by stay orders the same unit-level allocation and recordation provisions that would have applied under the Group 2 trading program or the Group 3 trading program, as applicable for the state, in the absence of the Good Neighbor Plan.[19]
- The revision of text at §§ 97.830(b)(1) and 97.834(d)(2)(i) to provide EGUs in states that were covered by the Group 3 trading program before 2023 the same deadlines for commencement of monitoring and reporting activities that would have applied in the absence of the Good Neighbor Plan.
- The addition of text at § 97.1026(e) to provide for the conversion of banked 2021–2022 Group 3 allowances held by EGUs in states that that were covered by the Group 3 trading program before 2023 into Expanded Group 2 allowances, with conforming revisions at §§ 97.502, 97.802, 97.1002, 97.824(c), and 52.38(b)(14).
- The revision of text at §§ 97.811(e)(1) and 97.826(e)(1) to exclude EGUs in states covered by stay orders from the Good Neighbor Plan's provisions converting banked 2017–2022 Original Group 2 allowances into Group 3 allowances and recalling previously allocated 2023–2024 Original Group 2 allowances.
- The revision of text at §§ 97.816(c), 97.818(f), and 97.820(c)(1)(iv), (c)(2)(iv), and (c)(5)(vi) to include the transition of states from the Group 3 trading program to the Group 2 trading program in the provisions that allow the EPA to treat certain certifications, applications, and notices of delegation as valid despite the use of terminology intended for use under a different trading program.
- The revision of text at §§ 97.526(e) and 97.826(f) and the addition of text at § 97.1026(f) to include the transition of states from the Group 3 trading program to the Group 2 trading program in the provisions that specify when and how an EGU in a state that has moved between trading programs may use allowances from a later trading program to meet surrender requirements for past control periods under a previous trading program, with conforming revisions at § 52.38(b)(14).
- The revision of text at § 97.526(d)(2)(ii) and 97.826(d)(3) to include the conversion of Group 3 allowances to Expanded Group 2 allowances in the provisions that address future conversions of allowances that were allocated for past control periods under a given trading program to an EGU in a state no longer covered by that trading program, where the allowances would have been included in a previous conversion to a different type of allowances if the allocations had been recorded before the previous conversion took place.

B. Deadline Corrections

In addition to the regulatory revisions described in section II.A of this document that are being made on an interim basis in response to judicial stay orders, in this action the EPA is also permanently revising three near-term deadlines that are incorrect in the Good Neighbor Plan as published in the **Federal Register**. Unlike the revisions described in section II.A of this document, these revisions apply to emissions sources in the states whose coverage under the Good Neighbor Plan is not affected by a stay order.

The first deadline correction concerns a quarterly reporting deadline applicable to EGUs in states that were already covered by the Group 2 trading program or the Group 3 trading program before the 2023 ozone season. As explained in the Good Neighbor Plan preamble, these EGUs will participate in the revised Group 3 trading program for the entire 2023 ozone season, subject to transitional provisions ensuring that the only substantive new regulatory

[16] *See* §§ 52.184(b)(2) (Arkansas), 52.940(c)(2) (Kentucky), 52.984(e)(2) (Louisiana), 52.1284(b)(2) (Mississippi), 52.1326(c)(2) (Missouri), and 52.2283(e)(2) (Texas).

[17] *See* §§ 52.184(a)(6) (Arkansas), 52.940(b)(6) (Kentucky), 52.984(d)(6) (Louisiana), 52.1284(a)(6) (Mississippi), 52.1326(b)(6) (Missouri), and 52.2283(d)(6) (Texas).

[18] This revision ensures that Missouri's good neighbor obligations with respect to the 2008 and 1997 NAAQS can continue to be met through the participation of the state's EGUs in the state Group 2 trading program adopted by the state and included in the SIP revision that was approved by the EPA at 84 FR 66316 (December 4, 2019).

[19] For sources in states that were not covered by the Group 3 trading program before the Good Neighbor Plan, the applicable notice of data availability (NODA) referenced in revised § 97.811(a)(2)(i) as identifying the unit-level allocations of Original Group 2 allowances to existing units will be the NODA published at 81 FR 67190 (September 30, 2016) to implement the CSAPR Update. For sources in states that were covered by the Group 3 trading program before the Good Neighbor Plan, the applicable NODA referenced in revised § 97.811(a)(2)(ii) as identifying the unit-level allocations of Expanded Group 2 allowances to existing units will be the NODA published at 86 FR 26719 (May 17, 2021) to implement the Revised CSAPR Update.

requirements in 2023—specifically, the emissions control stringencies reflected in the revised Group 3 trading program's state emissions budgets and assurance levels—will take effect only after the Rule's effective date.[20] The Group 3 trading program's deadline for EGUs to submit quarterly reports of emissions and operating data for the first two months of the May–September ozone season in 2023 would normally have been July 31, 2023 (the first business day at least 30 days after the end of the second calendar quarter), but the timing of publication in the **Federal Register** caused the Good Neighbor Plan's effective date to fall four days after this date, on August 4, 2023. Accordingly, the EPA is extending the deadline in 40 CFR 97.1034(d)(3) by which EGUs subject to the Group 3 trading program must submit quarterly reports for this calendar quarter to August 4, 2023.[21] Further, because the quarterly reports required under the Group 3 trading program are consolidated with the quarterly reports required under several other EPA programs, the EPA is also amending 40 CFR 97.1034(d)(4) to similarly extend these EGUs' reporting deadlines under the other programs.

The second deadline correction concerns a quarterly reporting deadline applicable to EGUs in states that were not already covered by the Group 2 trading program or the Group 3 trading program before the 2023 ozone season. EGUs in these states will begin to participate in the Group 3 trading program as of the Good Neighbor Plan's effective date, and the regulations as published in the Rule correctly provide that most of these EGUs will be subject to the program's monitoring and reporting requirements for emissions occurring on and after August 4, 2023.[22] However, a separate regulatory provision incorrectly identifies the ending date of the first calendar quarter for which these EGUs must submit quarterly reports under the Group 3 trading program as June 30, 2023. The EPA is amending 40 CFR 97.1034(d)(2)(i)(C) to indicate the correct quarterly ending date of September 30, 2023. The deadline for EGUs to submit quarterly reports for this calendar quarter will be October 30, 2023.

The third deadline correction concerns a deadline for submission of initial notifications applicable to furnaces in the Glass and Glass Product Manufacturing industry that are subject to requirements under the Good Neighbor Plan. Because of a typographical error in the document submitted for publication in the **Federal Register**,the Rule as published incorrectly specifies a submission deadline of June 23, 2023 (the first business day at least 18 days after the Rule's publication date). The EPA is amending 40 CFR 52.44(j)(2) to specify the intended submission deadline of December 4, 2023 (the first business day at least *180* days after the Rule's publication date).

III. Rulemaking Procedures and Findings of Good Cause

As noted in section I.C of this document, the EPA's authority for the rulemaking procedures followed in this action is provided by APA section 553.[23] In general, an agency issuing a rule under the procedures in APA section 553 must provide prior notice and an opportunity for public comment, but APA section 553(b)(B) includes an exemption from notice-and-comment requirements ''when the agency for good cause finds (and incorporates the finding and a brief statement of reasons therefor in the rule issued) that notice and public procedure thereon are impracticable, unnecessary, or contrary to the public interest.'' This action is being issued as an interim final rule without prior notice or opportunity for public comment because the EPA finds that the APA ''good cause'' exemption from notice-and-comment requirements applies here.

The EPA finds good cause to forgo notice-and-comment procedures because such procedures are both impracticable and unnecessary for this action. First, following notice-and-comment procedures is impracticable for the portions of this action responding to the stay orders because such procedures would require more time than is available. The earliest stay order to which the EPA must respond in this action was issued on May 1, 2023, just over three months before the Good Neighbor Plan's upcoming effective date on August 4, 2023, which is the date by which this action responding to the stay order must be effective. The most recent of the subsequent stay orders to which the EPA's action must also respond was issued less than two months before the Rule's upcoming effective date. The EPA does not consider even the maximum three-month period sufficient time in which to conduct a notice-and-comment rulemaking encompassing the time to, at a minimum, evaluate possible actions for responding to the stay orders, prepare and publish a proposal describing the action identified through that evaluation, wait for comments on the proposal, review the comments received, and prepare and publish a final rule and response to comments. It is not possible for all of these steps to be completed within a three-month period for this action.

Second, following notice-and-comment procedures is unnecessary for this action. With respect to the portions of this action that respond to the stay orders, the EPA has no discretion as to the regulatory revisions that stay the effectiveness of the Good Neighbor Plan's requirements for sources in the states covered by stay orders. While some superficial discretion exists concerning the specific design of the regulatory revisions that provide an alternate mechanism for EGUs in states covered by the stay orders to continue to address the states' good neighbor obligations with respect to the 2008 and 1997 NAAQS, no discretion exists as to the function of that design, which is to maintain the status quo by implementing requirements that are substantively identical to the pre-existing requirements that would have continued to apply in the absence of the Good Neighbor Plan. The EPA's design for the regulatory revisions in this action accomplishes this function. Taking comment on the portions of the action that respond to the stay orders so as to allow the public to advocate for not staying the Good Neighbor Plan's requirements, not adopting regulatory

[20] *See* 88 FR 36775–76; 88 FR 36811–13.

[21] All the EGUs that are required under the Good Neighbor Plan to submit quarterly reports for the second calendar quarter of 2023 already participate in either the Group 2 trading program or the Group 3 trading program and therefore have already installed and certified the necessary monitoring systems. The data elements of the quarterly reports that these EGUs are required to submit under the Group 3 trading program for their ozone season emissions in 2023 are identical to the data elements of the quarterly reports that the EGUs were required to submit under the Group 2 trading program or Group 3 trading program for their ozone season emissions in 2022 and previous years.

[22] *See* 40 CFR 97.1030(b)(1)(iii). Most EGUs covered under the Good Neighbor Plan that do not already participate in the Group 2 trading program or the Group 3 trading program are already subject to closely related monitoring and reporting requirements under other EPA programs and consequently have already installed and certified the monitoring systems necessary to monitor and report under the Group 3 trading program. For the small number of EGUs in these states that have not already been required to install and certify the necessary monitoring systems under another EPA program, the deadline to begin monitoring and reporting under the Group 3 trading program will be either January 31, 2024 (180 days after the Rule's effective date), for units that report on a year-round basis, or May 1, 2024, for units that report on an ozone season-only basis. *See* 40 CFR 97.1030(b)(1)(iv) and (b)(3).

[23] Under CAA section 307(d)(1)(B), the EPA's revision of a FIP under CAA section 110(c) would normally be subject to the rulemaking procedural requirements of CAA section 307(d), including notice-and-comment procedures, but CAA section 307(d) does not apply ''in the case of any rule or circumstance referred to in subparagraphs (A) or (B) of [APA section 553(b)].'' CAA section 307(d)(1).

revisions needed to implement requirements that are substantively identical to the requirements that would have applied in the absence of the Good Neighbor Plan, or adopting superficially different regulatory revisions to accomplish the same function would serve no purpose and is therefore unnecessary.[24]

With respect to the portions of this action that correct deadlines, each of the deadlines that is incorrect as published in the Good Neighbor Plan precedes the Rule's actual effective date and therefore could not be implemented as published. In the cases of the two deadlines that were incorrect as published because of the timing of the Rule's publication, the amended deadlines of August 4, 2023, and September 30, 2023, are the earliest possible revised deadlines that are both feasible in light of the Good Neighbor Plan's actual effective date and also consistent with the normal timing and sequence of monitoring and reporting activities under the Group 3 trading program regulations. In the case of the deadline that was incorrect as published because of a typographical error, the amended deadline of December 4, 2023, is the same deadline that has already been published in parallel provisions of the Good Neighbor Plan's regulations for other non-EGU industrial sources.[25] Because both the need for the corrections and the specific corrections that should be made are clear, taking comment to allow the public to advocate for not correcting the deadlines or for making different corrections would serve no purpose and is therefore unnecessary.

The regulatory revisions made in this action will take effect on August 4, 2023, the effective date of the Good Neighbor Plan. In general, an agency issuing a rule under APA section 553 must provide for a period of at least 30 days between the rule's dates of publication and effectiveness, but APA section 553(d) includes several exceptions. Under APA section 553(d)(1), an exception applies to a rule that ''grants or recognizes an exemption or relieves a restriction.'' Because the portions of this action that stay the effectiveness of the Good Neighbor Plan's requirements for the sources in certain states grant an exemption (on an interim basis while the stay remains in place), the normal 30-day minimum period between this action's dates of publication and effectiveness is not required. The EPA is making these portions of the action effective as of the Good Neighbor Plan's effective date to comply with the stay orders.

Under APA section 553(d)(3), the normal 30-day minimum period between a rule's dates of publication and effectiveness does not apply ''as otherwise provided by the agency for good cause found and published with the rule.'' With respect to the portions of this action that provide an alternate mechanism for EGUs in states covered by the stay orders to continue to address the states' good neighbor obligations under rules issued before the Good Neighbor Plan and the portions of this action that correct certain deadlines, the EPA finds good cause to make the regulatory revisions effective on August 4, 2023, the effective date of the Good Neighbor Plan, even though that date is less than 30 days after the publication date of this action, for the following reasons. First, the regulatory revisions that facilitate continued implementation of requirements addressing good neighbor obligations under previous rules benefit the public by avoiding the possibility that interruption of the requirements would cause air quality degradation. Second, both these regulatory revisions and the regulatory revisions that correct deadlines benefit the regulated community by clarifying the regulatory requirements that apply in light of the stay orders and the timing of publication of the Good Neighbor Plan. Finally, making the regulatory revisions effective less than 30 days after this action's publication date does not violate the purpose of the normal requirement for a 30-day minimum period, which is ''to give affected parties a reasonable time to adjust their behavior before the final rule takes effect.''[26] The regulatory revisions in this action facilitating continued implementation of previously applicable requirements impose no requirements on any source that differ substantively from the requirements that would have applied to that source in the absence of the Good Neighbor Plan, and the deadline corrections in this action extend the deadlines in the Rule as published. Thus, no affected party needs time to adjust its behavior in preparation for these regulatory revisions.

IV. Request for Comment

As explained in section III of this document, the EPA finds good cause to take this interim final action without prior notice or opportunity for public comment. However, the EPA is providing an opportunity for comment on the content of the amendments. The EPA requests comment on this rule. The EPA is not reopening for comment any provisions of the Good Neighbor Plan, 40 CFR part 52, or 40 CFR part 97 other than the specific provisions that are expressly added or amended in this rule.

V. Statutory and Executive Order Reviews

Additional information about these statutes and Executive Orders can be found at *www.epa.gov/laws-regulations/laws-and-executive-orders.*

A. Executive Order 12866: Regulatory Planning and Review, as Amended by Executive Order 14094: Modernizing Regulatory Review

This action is not a significant regulatory action as defined in Executive Order 12866, as amended by Executive Order 14094, and was therefore not subject to a requirement for Executive Order 12866 review.

B. Paperwork Reduction Act (PRA)

This action does not impose any new information collection burden under the Paperwork Reduction Act (PRA), 44 U.S.C. 3501 *et seq.* The Office of Management and Budget (OMB) has previously approved the information collection activities that will apply to the EGUs affected by this action and has assigned OMB control numbers 2060–0258 and 2060–0667. Additional information collection activities that will apply to EGUs and non-EGU industrial sources under the Good Neighbor Plan have been submitted to OMB for approval in conjunction with that rulemaking. This action makes no changes to the information collection activities under the previously approved information collection requests (ICRs) or the additional information collection activities for which approval has been requested in the Good Neighbor Plan's ICRs.

C. Regulatory Flexibility Act (RFA)

This action is not subject to the Regulatory Flexibility Act (RFA), 5.U.S.C. 601–612. The RFA applies only to rules subject to notice-and-comment rulemaking requirements under the Administrative Procedure Act (APA), 5 U.S.C. 553, or any other statute. This rule is not subject to notice-and-comment requirements because the

[24] To illustrate, the EPA could in theory preserve the status quo for EGUs in Kentucky and Louisiana by promulgating an entire set of trading program regulations under 40 CFR part 97 replicating the entire set of Group 3 trading program regulations as promulgated in the Revised CSAPR Update without the subsequent revisions promulgated in the Good Neighbor Plan to address states' good neighbor obligations with respect to the 2015 ozone NAAQS. However, the outcome would be substantively identical to the approach the EPA is taking here.

[25] *See* 40 CFR 52.42(g)(2); 40 CFR 52.43(h)(2).

[26] *Omnipoint Corp.* v. *FCC,* 78 F.3d 620, 630 (D.C. Cir. 1996).

Agency has invoked the APA "good cause" exemption under 5 U.S.C. 553(b).

D. Unfunded Mandates Reform Act (UMRA)

This action does not contain any unfunded mandate as described in the Unfunded Mandates Reform Act (UMRA), 2 U.S.C. 1531–1538, and does not significantly or uniquely affect small governments. This action imposes no enforceable duty on any state, local, or tribal governments or the private sector. This action simply stays the effectiveness of certain regulatory requirements for certain sources on an interim basis in response to procedural court orders while ensuring that previously applicable regulatory requirements remain in effect.

E. Executive Order 13132: Federalism

This action does not have federalism implications. It will not have substantial direct effects on the states, on the relationship between the national government and the states, or on the distribution of power and responsibilities among the various levels of government.

F. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments

This action does not have tribal implications as specified in Executive Order 13175. This action simply stays the effectiveness of certain regulatory requirements for certain sources on an interim basis in response to procedural court orders while ensuring that previously applicable regulatory requirements remain in effect. Thus, Executive Order 13175 does not apply to this action.

G. Executive Order 13045: Protection of Children From Environmental Health Risks and Safety Risks

The EPA interprets Executive Order 13045 as applying only to those regulatory actions that concern environmental health or safety risks that the EPA has reason to believe may disproportionately affect children, per the definition of "covered regulatory action" in section 2–202 of the Executive Order. This action responds to court orders issued by the U.S. Courts of Appeals for the Fifth, Sixth, and Eighth Circuits and the EPA lacks discretion to deviate from those orders. The EPA's assessment of health and safety risks for the action establishing the requirements that are being stayed is discussed in Chapter 5 of the regulatory impact analysis for the Good Neighbor Plan.[27]

H. Executive Order 13211: Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use

This action is not subject to Executive Order 13211 because it is not a significant regulatory action under Executive Order 12866.

I. National Technology Transfer and Advancement Act (NTTAA)

This rulemaking does not involve technical standards.

J. Executive Order 12898: Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations

Executive Order 12898 (59 FR 7629, February 16, 1994) directs federal agencies, to the greatest extent practicable and permitted by law, to make environmental justice part of their mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority populations (people of color and/or Indigenous peoples) and low-income populations.

This action responds to court orders issued by the U.S. Courts of Appeals for the Fifth, Sixth, and Eighth Circuits and the EPA lacks discretion to deviate from those orders. The EPA's assessment of environmental justice considerations for the action establishing the requirements that are being stayed is discussed in section VII of the Good Neighbor Plan preamble.[28]

K. Congressional Review Act (CRA)

This action is subject to the Congressional Review Act (CRA), 5 U.S.C. 801–808, and the EPA will submit a rule report to each House of the Congress and to the Comptroller General of the United States. The CRA allows the issuing agency to make a rule effective sooner than otherwise provided by the CRA if the agency makes a good cause finding that notice and comment rulemaking procedures are impracticable, unnecessary, or contrary to the public interest (5 U.S.C. 808(2)). The EPA has made a good cause finding for this rule as discussed in section III of this document, including the basis for that finding.

L. Judicial Review

CAA section 307(b)(1) governs judicial review of final actions by the EPA. This section provides, in part, that petitions for review must be filed in the U.S. Court of Appeals for the District of Columbia Circuit (D.C. Circuit): (i) when the agency action consists of "nationally applicable regulations promulgated, or final actions taken, by the Administrator," or (ii) when such action is locally or regionally applicable, but "such action is based on a determination of nationwide scope or effect and if in taking such action the Administrator finds and publishes that such action is based on such a determination." For locally or regionally applicable final actions, the CAA reserves to the EPA complete discretion to decide whether to invoke the exception in (ii).[29]

This rulemaking is "nationally applicable" within the meaning of CAA section 307(b)(1). In this action, in response to court orders, the EPA is amending on an interim basis the Good Neighbor Plan,[30] which the EPA developed by applying a uniform legal interpretation and common, nationwide analytical methods to address the requirements of CAA section 110(a)(2)(D)(i)(I) concerning interstate transport of pollution (*i.e.,* "good neighbor" requirements) for the 2015 ozone NAAQS. Based on that nationwide analysis, the Good Neighbor Plan established FIP requirements for sources in 23 states located across eight EPA Regions and ten federal judicial circuits. Given that this action amends an action implementing the good neighbor requirements of CAA section 110(a)(2)(D)(i)(I) in a large number of states located across the country and given the interdependent nature of interstate pollution transport and the common core of knowledge and analysis involved in promulgating the FIP requirements, this is a "nationally applicable" action within the meaning of CAA section 307(b)(1).

In the alternative, to the extent a court finds this action to be locally or regionally applicable, the Administrator is exercising the complete discretion afforded to him under the CAA to make and publish a finding that this action is based on a determination of

[27] *See* Regulatory Impact Analysis for the Final Federal Good Neighbor Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standard (March 2023) at 197–257, available in the docket.

[28] *See* 88 FR 36844–46.

[29] *Sierra Club* v. *EPA,* 47 F.4th 738, 745 (D.C. Cir. 2022) ("EPA's decision whether to make and publish a finding of nationwide scope or effect is committed to the agency's discretion and thus is unreviewable"); *Texas* v. *EPA,* 983 F.3d 826, 834–35 (5th Cir. 2020).

[30] The Good Neighbor Plan is nationally applicable or based on a determination of nationwide scope or effect found and published by the EPA. *See* 88 FR 36859–60.

''nationwide scope or effect'' within the meaning of CAA section 307(b)(1). In this action, in response to court orders, the EPA is amending on an interim basis the Good Neighbor Plan, an action in which the EPA interpreted and applied section 110(a)(2)(D)(i)(I) of the CAA for the 2015 ozone NAAQS based on a common core of nationwide policy judgments and technical analysis concerning the interstate transport of pollutants throughout the continental United States. Based on that nationwide analysis, the Good Neighbor Plan established FIP requirements for sources in 23 states located across eight EPA Regions and ten federal judicial circuits. This action adjusts temporarily the scope and operation of the Good Neighbor Plan for six states in response to court orders, and also implements necessary measures to ensure the status quo is maintained with respect to existing obligations under previously issued regulations (that were themselves nationally applicable or based on a determination of nationwide scope or effect found and published by the EPA [31]). This action also adjusts certain deadlines for all states that remain covered by the Good Neighbor Plan.

The Administrator finds that, like the Good Neighbor Plan which it amends, this action is a matter on which national uniformity in judicial resolution of any petitions for review is desirable, to take advantage of the D.C. Circuit's administrative law expertise, and to facilitate the orderly development of the basic law under the Act. The Administrator also finds that consolidated review of this action in the D.C. Circuit will avoid piecemeal litigation in the regional circuits, further judicial economy, and eliminate the risk of inconsistent results for different states, and that a nationally consistent approach to the CAA's mandate concerning interstate transport of ozone pollution constitutes the best use of Agency resources.

For these reasons, this final action is nationally applicable or, alternatively, the Administrator is exercising the complete discretion afforded to him by the CAA and finds that this final action is based on a determination of nationwide scope or effect for purposes of CAA section 307(b)(1) and is publishing that finding in the **Federal Register**. Under CAA section 307(b)(1), petitions for judicial review of this action must be filed in the D.C. Circuit by September 29, 2023.

[31] *See* 86 FR 23163–64; 81 FR 74585–86.

List of Subjects

40 CFR Part 52

Environmental protection, Administrative practice and procedure, Air pollution control, Incorporation by reference, Intergovernmental relations, Nitrogen oxides, Ozone, Particulate matter, Sulfur dioxide.

40 CFR Part 97

Environmental protection, Administrative practice and procedure, Air pollution control, Electric power plants, Nitrogen oxides, Ozone, Particulate matter, Reporting and recordkeeping requirements, Sulfur dioxide.

Michael S. Regan,
Administrator.

For the reasons stated in the preamble, parts 52 and 97 of title 40 of the Code of Federal Regulations are amended as follows:

PART 52—APPROVAL AND PROMULGATION OF IMPLEMENTATION PLANS

■ 1. The authority citation for part 52 continues to read as follows:

Authority: 42 U.S.C. 7401 *et seq.*

Subpart A—General Provisions

■ 2. Amend § 52.38 by:
■ a. Adding paragraphs (b)(2)(ii)(D) and (b)(2)(iii)(D);
■ b. In paragraph (b)(11)(iii)(D), removing ''and'' after the semicolon;
■ c. In paragraph (b)(14)(i)(F), removing ''and'' after the semicolon;
■ d. Revising paragraph (b)(14)(i)(G);
■ e. Adding paragraph (b)(14)(i)(H);
■ f. Revising paragraphs (b)(14)(iii) introductory text and (b)(14)(iii)(B);
■ g. In paragraph (b)(14)(iii)(C), adding ''Original'' before ''Group 2 allowances'' each time it appears; and
■ h. In paragraph (b)(16)(ii)(B), adding ''and not listed in paragraph (b)(2)(ii)(D)(*2*) of this section'' before ''and any control period''.

The additions and revisions read as follows:

§ 52.38 What are the requirements of the Federal Implementation Plans (FIPs) for the Cross-State Air Pollution Rule (CSAPR) relating to emissions of nitrogen oxides?

* * * * *

(b) * * *
(2) * * *
(ii) * * *
(D) Notwithstanding any other provision of this part:

(*1*) While a stay under paragraph (b)(2)(iii)(D)(*1*) of this section is in effect for the sources in a State and Indian country located within the borders of such State with regard to emissions occurring in a control period in a given year—

(*i*) The provisions of subpart EEEEE of part 97 of this chapter (as modified in any approval of a SIP revision for such State by the Administrator under paragraph (b)(8) of this section) or the provisions of a SIP revision approved for such State by the Administrator under paragraph (b)(9) of this section, if any, shall apply to the sources in such State and areas of Indian country within the borders of such State subject to the State's SIP authority, and the provisions of subpart EEEEE of part 97 of this chapter shall apply to the sources in areas of Indian country within the borders of such State not subject to the State's SIP authority, with regard to emissions occurring in such control period; and

(*ii*) Such State shall be deemed to be listed in this paragraph (b)(2)(ii)(D)(*1*) for purposes of this part and part 97 of this chapter.

(*2*) While a stay under paragraph (b)(2)(iii)(D)(*2*) of this section is in effect for the sources in a State and Indian country located within the borders of such State with regard to emissions occurring in a control period in a given year—

(*i*) The provisions of subpart EEEEE of part 97 of this chapter (as modified in any approval of a SIP revision for such State by the Administrator under paragraph (b)(8) of this section) or the provisions of a SIP revision approved for such State by the Administrator under paragraph (b)(9) of this section, if any, shall apply to the sources in such State and areas of Indian country within the borders of such State subject to the State's SIP authority, and the provisions of subpart EEEEE of part 97 of this chapter shall apply to the sources in areas of Indian country within the borders of such State not subject to the State's SIP authority, with regard to emissions occurring in such control period; and

(*ii*) Such State shall be deemed to be listed in this paragraph (b)(2)(ii)(D)(*2*) for purposes of this part and part 97 of this chapter.

(iii) * * *
(D) Notwithstanding any other provision of this part:

(*1*) The effectiveness of paragraph (b)(2)(iii)(A) of this section is stayed for sources in Kentucky and Louisiana and Indian country located within the borders of such States with regard to emissions occurring in 2023 and thereafter. While a stay under this paragraph (b)(2)(iii)(D)(*1*) is in effect for a State, such State shall be deemed not to be listed in paragraph (b)(2)(iii)(A) of this section for purposes of part 97 of this chapter for a control period after 2022.

(*2*) The effectiveness of paragraph (b)(2)(iii)(B) of this section is stayed for sources in Arkansas, Mississippi, Missouri, and Texas and Indian country located within the borders of such States with regard to emissions occurring in 2023 and thereafter. While a stay under this paragraph (b)(2)(iii)(D)(*2*) is in effect for a State, such State shall be deemed not to be listed in paragraph (b)(2)(iii)(B) of this section for purposes of part 97 of this chapter.

* * * * *

(14) * * *

(i) * * *

(G) The provisions in § 97.526(e) of this chapter or § 97.826(f) of this chapter (concerning the use of CSAPR NO_X Ozone Season Original Group 2 allowances, CSAPR NO_X Ozone Season Expanded Group 2 allowances, or CSAPR NO_X Ozone Season Group 3 allowances to satisfy requirements to hold CSAPR NO_X Ozone Season Group 1 allowances or the use of CSAPR NO_X Ozone Season Expanded Group 2 allowances or CSAPR NO_X Ozone Season Group 3 allowances to satisfy requirements to hold CSAPR NO_X Ozone Season Original Group 2 allowances); and

(H) The provisions in §§ 97.806(c), 97.824(a) and (d), and 97.825(a) of this chapter (concerning the situations for which compliance requirements are defined in terms of either CSAPR NO_X Ozone Season Original Group 2 allowances or CSAPR NO_X Ozone Season Expanded Group 2 allowances).

* * * * *

(iii) Notwithstanding any discontinuation pursuant to paragraphs (b)(2)(i)(B), (b)(2)(ii)(B) or (C), (b)(2)(iii)(D)(*1*), or (b)(13)(i) of this section of the applicability of subpart BBBBB, EEEEE, or GGGGG of part 97 of this chapter to the sources in a State and areas of Indian country within the borders of the State subject to the State's SIP authority with regard to emissions occurring in any control period, the following provisions shall continue to apply with regard to all CSAPR NO_X Ozone Season Group 1 allowances, CSAPR NO_X Ozone Season Group 2 allowances, and CSAPR NO_X Ozone Season Group 3 allowances at any time allocated for any control period to any source or other entity in the State and areas of Indian country within the borders of the State subject to the State's SIP authority and shall apply to all entities, wherever located, that at any time held or hold such allowances:

* * * * *

(B) The provisions of §§ 97.526(d), 97.826(d) and (e), and 97.1026(e) of this chapter (concerning the conversion of unused CSAPR NO_X Ozone Season Group 1 allowances allocated for specified control periods to different amounts of CSAPR NO_X Ozone Season Original Group 2 allowances or CSAPR NO_X Ozone Season Group 3 allowances, the conversion of unused CSAPR NO_X Ozone Season Original Group 2 allowances allocated for specified control periods to different amounts of CSAPR NO_X Ozone Season Group 3 allowances, and the conversion of unused CSAPR NO_X Ozone Season Group 3 allowances allocated for specified control periods to CSAPR NO_X Ozone Season Expanded Group 2 allowances); and

* * * * *

■ 3. Amend § 52.40 by adding paragraph (c)(4) to read as follows:

§ 52.40 What are the requirements of the Federal Implementation Plans (FIPs) relating to ozone season emissions of nitrogen oxides from sources not subject to the CSAPR ozone season trading program?

* * * * *

(c) * * *

(4) Notwithstanding any other provision of this part, the effectiveness of paragraphs (a) and (b), (c)(1) through (3), and (d) through (g) of this section and §§ 52.41, 52.42, 52.43, 52.44, 52.45, and 52.46 is stayed for sources located in Arkansas, Kentucky, Louisiana, Mississippi, Missouri, and Texas, including Indian country located within the borders of such States.

* * * * *

§ 52.44 [Amended]

■ 4. Amend § 52.44(j)(2) by removing ''June 23, 2023'' and adding in its place ''December 4, 2023''.

Subpart E—Arkansas

■ 5. Amend § 52.184 by:

■ a. Adding paragraph (a)(6); and

■ b. Redesignating paragraph (b) as paragraph (b)(1) and adding paragraph (b)(2).

The additions read as follows:

§ 52.184 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

(a) * * *

(6) Notwithstanding any other provision of this part, the effectiveness of paragraph (a)(3) of this section is stayed with regard to emissions occurring in 2023 and thereafter, provided that while such stay remains in effect, the provisions of paragraph (a)(2) of this section shall apply with regard to such emissions.

(b) * * *

(2) Notwithstanding any other provision of this part, the effectiveness of paragraph (b)(1) of this section is stayed.

Subpart S—Kentucky

■ 6. Amend § 52.940 by:

■ a. Adding paragraph (b)(6); and

■ b. Redesignating paragraph (c) as paragraph (c)(1) and adding paragraph (c)(2).

The additions read as follows:

§ 52.940 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(b) * * *

(6) Notwithstanding any other provision of this part, the effectiveness of paragraph (b)(3) of this section is stayed with regard to emissions occurring in 2023 and thereafter, provided that while such stay remains in effect, the provisions of paragraph (b)(2) of this section shall apply with regard to such emissions.

(c) * * *

(2) Notwithstanding any other provision of this part, the effectiveness of paragraph (c)(1) of this section is stayed.

Subpart T—Louisiana

■ 7. Amend § 52.984 by:

■ a. Adding paragraph (d)(6); and

■ b. Redesignating paragraph (e) as paragraph (e)(1) and adding paragraph (e)(2).

The additions read as follows:

§ 52.984 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(d) * * *

(6) Notwithstanding any other provision of this part, the effectiveness of paragraph (d)(3) of this section is stayed with regard to emissions occurring in 2023 and thereafter, provided that while such stay remains in effect, the provisions of paragraph (d)(2) of this section shall apply with regard to such emissions.

(e) * * *

(2) Notwithstanding any other provision of this part, the effectiveness of paragraph (e)(1) of this section is stayed.

Subpart Z—Mississippi

■ 8. Amend § 52.1284 by:
■ a. Adding paragraph (a)(6); and
■ b. Redesignating paragraph (b) as paragraph (b)(1) and adding paragraph (b)(2).

The additions read as follows:

§ 52.1284 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

(a) * * *

(6) Notwithstanding any other provision of this part, the effectiveness of paragraph (a)(3) of this section is stayed with regard to emissions occurring in 2023 and thereafter, provided that while such stay remains in effect, the provisions of paragraph (a)(2) of this section shall apply with regard to such emissions.

(b) * * *

(2) Notwithstanding any other provision of this part, the effectiveness of paragraph (b)(1) of this section is stayed.

Subpart AA—Missouri

■ 9. Amend § 52.1326 by:
■ a. Adding paragraph (b)(6); and
■ b. Redesignating paragraph (c) as paragraph (c)(1) and adding paragraph (c)(2).

The additions read as follows:

§ 52.1326 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(b) * * *

(6) Notwithstanding any other provision of this part, the effectiveness of paragraph (b)(3) of this section is stayed with regard to emissions occurring in 2023 and thereafter, provided that while such stay remains in effect, the provisions of paragraph (b)(2) of this section shall apply with regard to such emissions.

(c) * * *

(2) Notwithstanding any other provision of this part, the effectiveness of paragraph (c)(1) of this section is stayed.

Subpart SS—Texas

■ 10. Amend § 52.2283 by:
■ a. Adding paragraph (d)(6); and
■ b. Redesignating paragraph (e) as paragraph (e)(1) and adding paragraph (e)(2).

The additions read as follows:

§ 52.2283 Interstate pollutant transport provisions; What are the FIP requirements for decreases in emissions of nitrogen oxides?

* * * * *

(d) * * *

(6) Notwithstanding any other provision of this part, the effectiveness of paragraph (d)(3) of this section is stayed with regard to emissions occurring in 2023 and thereafter, provided that while such stay remains in effect, the provisions of paragraph (d)(2) of this section shall apply with regard to such emissions.

(e) * * *

(2) Notwithstanding any other provision of this part, the effectiveness of paragraph (e)(1) of this section is stayed.

PART 97—FEDERAL NO_X BUDGET TRADING PROGRAM, CAIR NO_X AND SO_2 TRADING PROGRAMS, CSAPR NO_X AND SO_2 TRADING PROGRAMS, AND TEXAS SO_2 TRADING PROGRAM

■ 11. The authority citation for part 97 continues to read as follows:

Authority: 42 U.S.C. 7401, 7403, 7410, 7426, 7491, 7601, and 7651, *et seq.*

Subpart BBBBB—CSAPR NO_X Ozone Season Group 1 Trading Program

■ 12. Amend § 97.502 by:
■ a. Adding in alphabetical order a definition of "CSAPR NO_X Ozone Season Expanded Group 2 allowance";
■ b. Revising the definition of "CSAPR NO_X Ozone Season Group 2 allowance"; and
■ c. Adding in alphabetical order a definition of "CSAPR NO_X Ozone Season Original Group 2 allowance".

The revision and additions read as follows:

§ 97.502 Definitions.

* * * * *

CSAPR NO_X Ozone Season Expanded Group 2 allowance means a CSAPR NO_X Ozone Season Group 2 allowance allocated for a control period after 2022 under subpart EEEEE of this part, § 97.526(d), or § 97.1026(e) to a unit in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) or allocated or auctioned for a control period after 2022 in accordance with the provisions of a SIP revision approved for such a State by the Administrator under § 52.38(b)(7), (8), or (9) of this chapter.

* * * * *

CSAPR NO_X Ozone Season Group 2 allowance means a limited authorization issued and allocated or auctioned by the Administrator under subpart EEEEE of this part, § 97.526(d), or § 97.1026(e), or by a State or permitting authority under a SIP revision approved by the Administrator under § 52.38(b)(7), (8), or (9) of this chapter, to emit one ton of NO_X during a control period of the specified calendar year for which the authorization is allocated or auctioned or of any calendar year thereafter under the CSAPR NO_X Ozone Season Group 2 Trading Program, where each CSAPR NO_X Ozone Season Group 2 allowance is either a CSAPR NO_X Ozone Season Original Group 2 allowance or a CSAPR NO_X Ozone Season Expanded Group 2 allowance.

* * * * *

CSAPR NO_X Ozone Season Original Group 2 allowance means a CSAPR NO_X Ozone Season Group 2 allowance other than a CSAPR NO_X Ozone Season Expanded Group 2 allowance.

* * * * *

■ 13. Amend § 97.526 by:
■ a. In paragraphs (d)(1)(iii) and (iv) and (d)(2)(i), adding "Original" before "Group 2 allowances" each time it appears;
■ b. Redesignating paragraph (d)(2)(ii) as paragraph (d)(2)(ii)(A);
■ c. In newly redesignated paragraph (d)(2)(ii)(A), removing "After the Administrator" and adding in its place "Except as provided in paragraph (d)(2)(ii)(B) of this section, after the Administrator";
■ d. Adding paragraph (d)(2)(ii)(B);
■ e. Revising paragraph (e) introductory text;
■ f. In paragraph (e)(1), adding "Original" before "Group 2 allowances";
■ g. Redesignating paragraph (e)(2) as paragraph (e)(2)(i);
■ h. In newly redesignated paragraph (e)(2)(i), removing "After the Administrator" and adding in its place "Except as provided in paragraph (e)(2)(ii) of this section, after the Administrator"; and
■ i. Adding paragraph (e)(2)(ii).

The additions and revision read as follows:

§ 97.526 Banking and conversion.

* * * * *

(d) * * *
(2) * * *
(ii) * * *

(B) After the Administrator has carried out the procedures set forth in paragraph (d)(1) of this section and §§ 97.826(d)(1) and 97.1026(e), upon any determination that would otherwise result in the initial recordation of a given number of CSAPR NO_X Ozone Season Group 1 allowances in the compliance account for a source in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State), the Administrator will not record such CSAPR NO_X Ozone Season Group 1 allowances but instead will allocate and record in such account an amount of CSAPR NO_X Ozone Season Expanded Group 2 allowances for the control period in 2023 computed as the quotient, rounded up to the nearest allowance, of such given number of CSAPR NO_X Ozone Season Group 1 allowances divided by the conversion factor determined under paragraph (d)(1)(ii) of this section and further divided by the conversion factor determined under § 97.826(d)(1)(i)(D).

* * * * *

(e) Notwithstanding any other provision of this subpart or any SIP revision approved under § 52.38(b)(4) or (5) of this chapter, CSAPR NO_X Ozone Season Original Group 2 allowances, CSAPR NO_X Ozone Season Expanded Group 2 allowances, or CSAPR NO_X Ozone Season Group 3 allowances may be used to satisfy requirements to hold CSAPR NO_X Ozone Season Group 1 allowances under this subpart as follows, provided that nothing in this paragraph (e) alters the time as of which any such allowance holding requirement must be met or limits any consequence of a failure to timely meet any such allowance holding requirement:

* * * * *

(2) * * *

(ii) After the Administrator has carried out the procedures set forth in paragraph (d)(1) of this section and §§ 97.826(d)(1) and 97.1026(e), the owner or operator of a CSAPR NO_X Ozone Season Group 1 source in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) may satisfy a requirement to hold a given number of CSAPR NO_X Ozone Season Group 1 allowances for the control period in 2015 or 2016 by holding instead, in a general account established for this sole purpose, an amount of CSAPR NO_X Ozone Season Expanded Group 2 allowances for the control period in 2021 (or any later control period for which the allowance transfer deadline defined in § 97.802 has passed) computed as the quotient, rounded up to the nearest allowance, of such given number of CSAPR NO_X Ozone Season Group 1 allowances divided by the conversion factor determined under paragraph (d)(1)(ii) of this section and further divided by the conversion factor determined under § 97.826(d)(1)(i)(D).

* * * * *

Subpart EEEEE—CSAPR NO_X Ozone Season Group 2 Trading Program

■ 14. Amend § 97.802 by:

■ a. In the definition of ''Allocate or allocation'', removing ''§ 97.526(d), and'' and adding in its place ''§§ 97.526(d), 97.826(d), and 97.1026(e), and'';

■ b. In the definition of ''Common designated representative's assurance level'', paragraph (2), removing ''§ 97.526(d)'' and adding in its place ''§ 97.526(d), § 97.826(d), or § 97.1026(e)'';

■ c. Adding in alphabetical order a definition of ''CSAPR NO_X Ozone Season Expanded Group 2 allowance'';

■ d. Revising the definition of ''CSAPR NO_X Ozone Season Group 2 allowance''; and

■ e. Adding in alphabetical order a definition of ''CSAPR NO_X Ozone Season Original Group 2 allowance''.

The additions and revision read as follows:

§ 97.802 Definitions.

* * * * *

CSAPR NO_X Ozone Season Expanded Group 2 allowance means a CSAPR NO_X Ozone Season Group 2 allowance allocated for a control period after 2022 under this subpart, § 97.526(d), or § 97.1026(e) to a unit in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) or allocated or auctioned for a control period after 2022 in accordance with the provisions of a SIP revision approved for such a State by the Administrator under § 52.38(b)(7), (8), or (9) of this chapter.

* * * * *

CSAPR NO_X Ozone Season Group 2 allowance means a limited authorization issued and allocated or auctioned by the Administrator under this subpart, § 97.526(d), or § 97.1026(e), or by a State or permitting authority under a SIP revision approved by the Administrator under § 52.38(b)(7), (8), or (9) of this chapter, to emit one ton of NO_X during a control period of the specified calendar year for which the authorization is allocated or auctioned or of any calendar year thereafter under the CSAPR NO_X Ozone Season Group 2 Trading Program, where each CSAPR NO_X Ozone Season Group 2 allowance is either a CSAPR NO_X Ozone Season Original Group 2 allowance or a CSAPR NO_X Ozone Season Expanded Group 2 allowance.

* * * * *

CSAPR NO_X Ozone Season Original Group 2 allowance means a CSAPR NO_X Ozone Season Group 2 allowance other than a CSAPR NO_X Ozone Season Expanded Group 2 allowance.

* * * * *

■ 15. Amend § 97.806 by:

■ a. In paragraph (c)(1)(i), adding ''for such source'' after ''available for deduction'';

■ b. In paragraph (c)(2)(i) introductory text, adding ''for such group'' after ''available for deduction'';

■ c. In paragraph (c)(4), amend the paragraph heading by adding ''*and type*'' after ''*Vintage*''; and

■ d. Adding paragraphs (c)(4)(iii) and (iv).

The additions read as follows:

§ 97.806 Standard requirements.

* * * * *

(c) * * *

(4) * * *

(iii) Except as provided in paragraph (c)(4)(iv) of this section, a CSAPR NO_X Ozone Season Group 2 allowance held for compliance with the requirements under paragraphs (c)(1)(i), (c)(1)(ii)(A), and (c)(2)(i) through (iii) of this section must be a CSAPR NO_X Ozone Season Original Group 2 allowance.

(iv) A CSAPR NO_X Ozone Season Group 2 allowance held for compliance with the requirements under paragraphs (c)(1)(i), (c)(1)(ii)(A), and (c)(2)(i) through (iii) of this section for a source or group of sources in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (or Indian country within the borders of such a State) for a control period after 2022 must be a CSAPR NO_X Ozone Season Expanded Group 2 allowance.

* * * * *

■ 16. Amend § 97.810 by:

■ a. In paragraphs (a)(2)(i) and (ii), removing ''through 2022'' and adding in its place ''and thereafter'';

■ b. Adding paragraphs (a)(8)(iv) through (vi) and (a)(9)(iv) through (vi);

■ c. In paragraphs (a)(12)(i) through (iii), (a)(13)(i) and (ii), (a)(20)(i) through (iii), and (b)(2), removing ''through 2022'' and adding in its place ''and thereafter'';

■ d. Redesignating paragraph (b)(8) as paragraph (b)(8)(i) and adding paragraph (b)(8)(ii);

■ e. Redesignating paragraph (b)(9) as paragraph (b)(9)(i) and adding paragraph (b)(9)(ii); and

■ f. In paragraphs (b)(12), (b)(13), and (b)(20), removing ''through 2022'' and adding in its place ''and thereafter''.

The additions read as follows:

§ 97.810 State NO_X Ozone Season Group 2 trading budgets, new unit set-asides, Indian country new unit set-asides, and variability limits.

(a) * * *

(8) * * *

(iv) The NO_X Ozone Season Group 2 trading budget for 2023 and thereafter is 14,051 tons.

(v) The new unit set-aside for 2023 and thereafter is 283 tons.

(vi) [Reserved]

(9) * * *

(iv) The NO_X Ozone Season Group 2 trading budget for 2023 and thereafter is 14,818 tons.

(v) The new unit set-aside for 2023 and thereafter is 430 tons.

(vi) The Indian country new unit set-aside for 2023 and thereafter is 15 tons.

* * * * *

(b) * * *

(8) * * *

(ii) The variability limit for Kentucky for 2023 and thereafter is 2,951 tons.

(9) * * *

(ii) The variability limit for Louisiana for 2023 and thereafter is 3,112 tons.

* * * * *

■ 17. Amend § 97.811 by:

■ a. Revising paragraph (a)(2);

■ b. In paragraphs (d)(1), (d)(2)(i), (d)(2)(ii)(A) through (C), (d)(3)(i) through (iii), (d)(3)(iv)(A) through (C), (d)(3)(v)(B) and (C), (d)(4)(i) through (iii), (d)(5) introductory text, (d)(5)(i) and (ii), and (d)(6), adding ''Original'' before ''Group 2'' each time it appears;

■ c. In paragraph (e)(1):

■ i. Adding ''and not listed in § 52.38(b)(2)(ii)(D)(*2*) of this chapter'' before ''(and Indian country''; and

■ ii. Adding ''Original'' before ''Group 2'' each time it appears; and

■ d. In paragraphs (e)(2)(i), (e)(2)(ii)(A) through (C), (e)(3)(i) through (iii), (e)(3)(iv)(A) through (C), (e)(3)(v)(B) and (C), (e)(4)(i) through (iii), (e)(5) introductory text, (e)(5)(i) and (ii), and (e)(6), adding ''Original'' before ''Group 2'' each time it appears.

The revision reads as follows:

§ 97.811 Timing requirements for CSAPR NO_X Ozone Season Group 2 allowance allocations.

(a) * * *

(2) Notwithstanding paragraph (a)(1) of this section:

(i) If a unit provided an allocation of CSAPR NO_X Ozone Season Original Group 2 allowances in the applicable notice of data availability issued under paragraph (a)(1) of this section does not operate, starting after 2016, during the control period in two consecutive years, such unit will not be allocated the CSAPR NO_X Ozone Season Original Group 2 allowances provided in such notice for the unit for the control periods in the fifth year after the first such year and in each year after that fifth year.

(ii) If a unit provided an allocation of CSAPR NO_X Ozone Season Expanded Group 2 allowances in the applicable notice of data availability issued under paragraph (a)(1) of this section does not operate, starting after 2020, during the control period in two consecutive years, such unit will not be allocated the CSAPR NO_X Ozone Season Expanded Group 2 allowances provided in such notice for the unit for the control periods in the fifth year after the first such year and in each year after that fifth year.

(iii) All CSAPR NO_X Ozone Season Group 2 allowances that would otherwise have been allocated to a unit described in paragraph (a)(2)(i) or (ii) of this section will be allocated to the new unit set-aside for the State where such unit is located and for the respective years involved. If such unit resumes operation, the Administrator will allocate CSAPR NO_X Ozone Season Group 2 allowances to the unit in accordance with paragraph (b) of this section.

* * * * *

■ 18. Amend § 97.816 by revising paragraph (c) to read as follows:

§ 97.816 Certificate of representation.

* * * * *

(c) A certificate of representation under this section, § 97.516, or § 97.1016 that complies with the provisions of paragraph (a) of this section except that it contains the phrase ''TR NO_X Ozone Season'' or the phrase ''CSAPR NO_X Ozone Season Group 3'' in place of the phrase ''CSAPR NO_X Ozone Season Group 2'' in the required certification statements will be considered a complete certificate of representation under this section, and the certification statements included in such certificate of representation will be interpreted for purposes of this subpart as if the phrase ''CSAPR NO_X Ozone Season Group 2'' appeared in place of the phrase ''TR NO_X Ozone Season'' or the phrase ''CSAPR NO_X Ozone Season Group 3''.

■ 19. Amend § 97.818 by redesignating paragraph (f) as paragraph (f)(1) and adding paragraph (f)(2) to read as follows:

§ 97.818 Delegation by designated representative and alternate designated representative.

* * * * *

(f) * * *

(2) A notice of delegation submitted under paragraph (c) of this section or § 97.1018(c) that complies with the provisions of paragraph (c) of this section except that it contains the terms ''40 CFR 97.1018(d)'' and ''40 CFR 97.1018'' in place of the terms ''40 CFR 97.818(d)'' and ''40 CFR 97.818'', respectively, in the required certification statements will be considered a valid notice of delegation submitted under paragraph (c) of this section, and the certification statements included in such notice of delegation will be interpreted for purposes of this subpart as if the terms ''40 CFR 97.818(d)'' and ''40 CFR 97.818'' appeared in place of the terms ''40 CFR 97.1018(d)'' and ''40 CFR 97.1018'', respectively.

■ 20. Amend § 97.820 by:

■ a. Revising paragraphs (c)(1)(iv) and (c)(2)(iv); and

■ b. Redesignating paragraph (c)(5)(vi) as paragraph (c)(5)(vi)(A) and adding paragraph (c)(5)(vi)(B).

The revisions and addition read as follows:

§ 97.820 Establishment of compliance accounts, assurance accounts, and general accounts.

* * * * *

(c) * * *

(1) * * *

(iv) An application for a general account under paragraph (c)(1) of this section, § 97.520(c)(1), or § 97.1020(c)(1) that complies with the provisions of paragraph (c)(1) of this section except that it contains the phrase ''TR NO_X Ozone Season'' or the phrase ''CSAPR NO_X Ozone Season Group 3'' in place of the phrase ''CSAPR NO_X Ozone Season Group 2'' in the required certification statement will be considered a complete application for a general account under paragraph (c)(1) of this section, and the certification statement included in such application for a general account will be interpreted for purposes of this subpart as if the phrase ''CSAPR NO_X Ozone Season Group 2'' appeared in place of the phrase ''TR NO_X Ozone Season'' or the phrase ''CSAPR NO_X Ozone Season Group 3''.

(2) * * *

(iv) A certification statement submitted in accordance with paragraph (c)(2)(ii) of this section that contains the phrase ''TR NO_X Ozone Season'' or the phrase ''CSAPR NO_X Ozone Season Group 3'' will be interpreted for purposes of this subpart as if the phrase ''CSAPR NO_X Ozone Season Group 2'' appeared in place of the phrase ''TR NO_X Ozone Season'' or the phrase ''CSAPR NO_X Ozone Season Group 3''.

* * * * *

(5) * * *

(vi) * * *

(B) A notice of delegation submitted under paragraph (c)(5)(iii) of this section or § 97.1020(c)(5)(iii) that complies with the provisions of paragraph (c)(5)(iii) of this section except that it contains the terms ''40 CFR 97.1020(c)(5)(iv)'' and ''40 CFR 97.1020(c)(5)'' in place of the terms ''40 CFR 97.820(c)(5)(iv)'' and ''40 CFR 97.820(c)(5)'', respectively, in the required certification statements will be considered a valid notice of delegation submitted under paragraph (c)(5)(iii) of this section, and the certification statements included in such notice of delegation will be interpreted for purposes of this subpart as if the terms ''40 CFR 97.820(c)(5)(iv)'' and ''40 CFR 97.820(c)(5)'' appeared in place of the terms ''40 CFR 97.1020(c)(5)(iv)'' and ''40 CFR 97.1020(c)(5)'', respectively.

* * * * *

■ 21. Amend § 97.821 by:
■ a. Redesignating paragraph (e) as paragraph (e)(1);
■ b. In newly redesignated paragraph (e)(1), adding ''Original'' before ''Group 2 allowances'' each time it appears; and
■ c. Adding paragraph (e)(2).

The addition reads as follows:

§ 97.821 Recordation of CSAPR NO_X Ozone Season Group 2 allowance allocations and auction results.

* * * * *

(e) * * *

(2) By September 5, 2023, the Administrator will record in each CSAPR NO_X Ozone Season Group 2 source's compliance account the CSAPR NO_X Ozone Season Expanded Group 2 allowances allocated to the CSAPR NO_X Ozone Season Group 2 units at the source in accordance with § 97.811(a) for the control periods in 2023 and 2024.

* * * * *

■ 22. Amend § 97.824 by:
■ a. In paragraph (a)(1), removing ''and'' after the semicolon;
■ b. Adding paragraphs (a)(3) and (4);
■ c. In paragraph (c)(2)(ii), removing ''§ 97.526(d), in'' and adding in its place ''§ 97.526(d), § 97.826(d), or § 97.1026(e), in''; and
■ d. Revising paragraph (d).

The additions and revision read as follows:

§ 97.824 Compliance with CSAPR NO_X Ozone Season Group 2 emissions limitation.

(a) * * *

(3) Are CSAPR NO_X Ozone Season Original Group 2 allowances, if the deductions are not for compliance with the CSAPR NO_X Ozone Season Group 2 emissions limitation of a source in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) for a control period after 2022; and

(4) Are CSAPR NO_X Ozone Season Expanded Group 2 allowances, if the deductions are for compliance with the CSAPR NO_X Ozone Season Group 2 emissions limitation of a source in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) for a control period after 2022.

* * * * *

(d) *Deductions for excess emissions.* After making the deductions for compliance under paragraph (b) of this section for a control period in a year in which the CSAPR NO_X Ozone Season Group 2 source has excess emissions, the Administrator will deduct from the source's compliance account an amount of CSAPR NO_X Ozone Season Group 2 allowances, allocated or auctioned for a control period in a prior year or the control period in the year of the excess emissions or in the immediately following year, equal to two times the number of tons of the source's excess emissions, provided that—

(1) The allowances deducted shall be CSAPR NO_X Ozone Season Original Group 2 allowances, if the excess emissions are not from a source in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) for a control period after 2022; and

(2) The allowances deducted shall be CSAPR NO_X Ozone Season Expanded Group 2 allowances, if the excess emissions are from a source in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) for a control period after 2022.

* * * * *

■ 23. Amend § 97.825 by:
■ a. In paragraph (a)(1), removing ''and'' after the semicolon; and
■ b. Adding paragraphs (a)(3) and (4).

The additions read as follows:

§ 97.825 Compliance with CSAPR NO_X Ozone Season Group 2 assurance provisions.

(a) * * *

(3) Are CSAPR NO_X Ozone Season Original Group 2 allowances, if the deductions are not for compliance with the CSAPR NO_X Ozone Season Group 2 assurance provisions by the owners and operators of a group of sources in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) for a control period after 2022; and

(4) Are CSAPR NO_X Ozone Season Expanded Group 2 allowances, if the deductions are for compliance with the CSAPR NO_X Ozone Season Group 2 assurance provisions by the owners and operators of a group of sources in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) for a control period after 2022.

* * * * *

■ 24. Amend § 97.826 by:
■ a. In paragraphs (d)(1)(i)(A) and (D), (d)(1)(ii)(A), (d)(1)(iii)(A), (d)(1)(iv)(A) and (B), and (d)(2)(ii), adding ''Original'' before ''Group 2 allowances'' each time it appears;
■ b. Redesignating paragraph (d)(3) as paragraph (d)(3)(i);
■ c. In newly redesignated paragraph (d)(3)(i):
■ i. Removing ''After the Administrator'' and adding in its place ''Except as provided in paragraph (d)(3)(ii) of this section, after the Administrator''; and
■ ii. Adding ''Original'' before ''Group 2 allowances'' each time it appears;
■ d. Adding paragraph (d)(3)(ii);
■ e. In paragraph (e)(1) introductory text, adding ''or (D)'' before ''of this chapter'';
■ f. In paragraphs (e)(1)(i), (e)(1)(ii)(A), (e)(1)(iii) and (iv), (e)(1)(v)(B), and (e)(2), adding ''Original'' before ''Group 2 allowances'' each time it appears;
■ g. Revising paragraph (f) introductory text;
■ h. Redesignating paragraph (f)(1) as paragraph (f)(1)(i);
■ i. In newly redesignated paragraph (f)(1)(i):
■ i. Removing ''After the Administrator'' and adding in its place ''Except as provided in paragraph (f)(1)(ii) of this section, after the Administrator''; and
■ ii. Adding ''Original'' before ''Group 2 allowances'' each time it appears;
■ j. Adding paragraph (f)(1)(ii); and
■ k. In paragraph (f)(2):
■ i. Adding ''and not listed in § 52.38(b)(ii)(D)(*2*) of this chapter'' before ''(and Indian country''; and
■ ii. Adding ''Original'' before ''Group 2 allowances'' each time it appears.

The additions and revision read as follows:

§ 97.826 Banking and conversion.

* * * * *

(d) * * *

(3) * * *

(ii) After the Administrator has carried out the procedures set forth in paragraph (d)(1) of this section and § 97.1026(e), upon any determination that would otherwise result in the initial recordation of a given number of CSAPR NO_X Ozone Season Original Group 2 allowances in the compliance account for a source in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State), the Administrator will not record such CSAPR NO_X Ozone Season Original Group 2 allowances but instead will allocate and record in such account an amount of CSAPR NO_X Ozone Season Expanded Group 2 allowances for the control period in 2023 computed as the quotient, rounded up to the nearest allowance, of such given number of CSAPR NO_X Ozone Season Original Group 2 allowances divided by the conversion factor determined under paragraph (d)(1)(i)(D) of this section.

* * * * *

(f) Notwithstanding any other provision of this subpart or any SIP revision approved under § 52.38(b)(8) or (9) of this chapter, CSAPR NO_X Ozone Season Expanded Group 2 allowances or CSAPR NO_X Ozone Season Group 3 allowances may be used to satisfy requirements to hold CSAPR NO_X Ozone Season Original Group 2 allowances under this subpart as follows, provided that nothing in this paragraph (f) alters the time as of which any such allowance holding requirement must be met or limits any consequence of a failure to timely meet any such allowance holding requirement:

(1) * * *

(ii) After the Administrator has carried out the procedures set forth in paragraph (d)(1) of this section and § 97.1026(e), the owner or operator of a CSAPR NO_X Ozone Season Group 2 source in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) may satisfy a requirement to hold a given number of CSAPR NO_X Ozone Season Original Group 2 allowances for a control period in 2017 through 2020 by holding instead, in a general account established for this sole purpose, an amount of CSAPR NO_X Ozone Season Expanded Group 2 allowances for the control period in 2023 (or any later control period for which the allowance transfer deadline defined in § 97.802 has passed) computed as the quotient, rounded up to the nearest allowance, of such given number of CSAPR NO_X Ozone Season Original Group 2 allowances divided by the conversion factor determined under paragraph (d)(1)(i)(D) of this section.

* * * * *

■ 25. Amend § 97.830 by revising paragraph (b)(1) to read as follows:

§ 97.830 General monitoring, recordkeeping, and reporting requirements.

* * * * *

(b) * * *

(1)(i) May 1, 2017, for a unit other than a unit described in paragraph (b)(1)(ii) of this section;

(ii) May 1, 2023, for a unit that did not commence commercial operation at least 180 calendar days before September 30, 2020 and that is located in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State);

* * * * *

■ 26. Amend § 97.834 by revising paragraph (d)(2)(i) to read as follows:

§ 97.834 Recordkeeping and reporting.

* * * * *

(d) * * *

(2) * * *

(i)(A) The calendar quarter covering May 1, 2017 through June 30, 2017, for a unit other than a unit described in paragraph (d)(2)(i)(B) of this section;

(B) The calendar quarter covering May 1, 2023 through June 30, 2023, for a unit that did not commence commercial operation at least 180 calendar days before September 30, 2020 and that is located in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State);

* * * * *

Subpart GGGGG—CSAPR NO_X Ozone Season Group 3 Trading Program

■ 27. Amend § 97.1002 by:

■ a. Adding in alphabetical order a definition of ''CSAPR NO_X Ozone Season Expanded Group 2 allowance'';

■ b. Revising the definition of ''CSAPR NO_X Ozone Season Group 2 allowance''; and

■ c. Adding in alphabetical order a definition of ''CSAPR NO_X Ozone Season Original Group 2 allowance''.

The additions and revision read as follows:

§ 97.1002 Definitions.

* * * * *

CSAPR NO_X Ozone Season Expanded Group 2 allowance means a CSAPR NO_X Ozone Season Group 2 allowance allocated for a control period after 2022 under subpart EEEEE of this part, § 97.526(d), or § 97.1026(e) to a unit in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) or allocated or auctioned for a control period after 2022 in accordance with the provisions of a SIP revision approved for such a State by the Administrator under § 52.38(b)(7), (8), or (9) of this chapter.

* * * * *

CSAPR NO_X Ozone Season Group 2 allowance means a limited authorization issued and allocated or auctioned by the Administrator under subpart EEEEE of this part, § 97.526(d), or § 97.1026(e), or by a State or permitting authority under a SIP revision approved by the Administrator under § 52.38(b)(7), (8), or (9) of this chapter, to emit one ton of NO_X during a control period of the specified calendar year for which the authorization is allocated or auctioned or of any calendar year thereafter under the CSAPR NO_X Ozone Season Group 2 Trading Program, where each CSAPR NO_X Ozone Season Group 2 allowance is either a CSAPR NO_X Ozone Season Original Group 2 allowance or a CSAPR NO_X Ozone Season Expanded Group 2 allowance.

* * * * *

CSAPR NO_X Ozone Season Original Group 2 allowance means a CSAPR NO_X Ozone Season Group 2 allowance other than a CSAPR NO_X Ozone Season Expanded Group 2 allowance.

* * * * *

■ 28. Amend § 97.1026 by:

■ a. Revising the section heading; and

■ b. Adding paragraphs (e) and (f).

The revision and additions read as follows:

§ 97.1026 Banking and conversion; bank recalibration.

* * * * *

(e) Notwithstanding any other provision of this subpart, by September 18, 2023, the Administrator will temporarily suspend acceptance of CSAPR NO_X Ozone Season Group 3 allowance transfers submitted under § 97.1022 and, before resuming acceptance of such transfers, will take the actions in paragraphs (e)(1) and (2) of this section with regard to every compliance account for a CSAPR NO_X Ozone Season Group 3 source in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State):

(1) The Administrator will deduct all CSAPR NO_X Ozone Season Group 3 allowances allocated for the control periods in 2021 and 2022 from each such compliance account.

(2) For each CSAPR NO_X Ozone Season Group 3 allowance deducted from a given source's compliance account under paragraph (e)(1) of this section, the Administrator will allocate to the source and record in the source's compliance account one CSAPR NO_X Ozone Season Expanded Group 2 allowance for the control period in 2023.

(f) Notwithstanding any other provision of this subpart, CSAPR NO_X Ozone Season Expanded Group 2 allowances may be used to satisfy requirements to hold CSAPR NO_X Ozone Season Group 3 allowances under this subpart as follows, provided that nothing in this paragraph (f) alters the time as of which any such allowance holding requirement must be met or limits any consequence of a failure to timely meet any such allowance holding requirement:

(1) After the Administrator has carried out the procedures set forth in paragraph (e) of this section, the owner or operator of a CSAPR NO_X Ozone Season Group 3 source in a State listed in § 52.38(b)(2)(ii)(D)(*1*) of this chapter (and Indian country within the borders of such a State) may satisfy a requirement to hold a given number of CSAPR NO_X Ozone Season Group 3 allowances for the control period in 2021 or 2022 by holding instead, in a general account established for this sole purpose, an equal amount of CSAPR NO_X Ozone Season Expanded Group 2 allowances for the control period in 2023 (or any later control period for which the allowance transfer deadline defined in § 97.802 has passed).

(2) [Reserved]

■ 29. Amend § 97.1034 by:

■ a. In paragraph (d)(2)(i)(C), removing ''June'' and adding in its place ''September'';

■ b. In paragraph (d)(3), revising the first sentence; and

■ c. In paragraph (d)(4), adding a second sentence.

The revision and addition read as follows:

§ 97.1034 Recordkeeping and reporting.

* * * * *

(d) * * *

(3) The designated representative shall submit each quarterly report to the Administrator within 30 days after the end of the calendar quarter covered by the report, except that quarterly reports required for the calendar quarter covering May 1, 2023, through June 30, 2023, shall be submitted by August 4, 2023. * * *

(4) * * * Notwithstanding the provisions of §§ 75.64(a), 75.73(f)(1), 97.434(d)(2), 97.634(d)(2), and 97.734(d)(2), the deadline for the designated representative of such a unit to submit the quarterly reports required under such additional programs for the calendar quarter covering May 1, 2023, through June 30, 2023, shall be August 4, 2023.

* * * * *

BILLING CODE 6560–50–P

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Centers for Medicare & Medicaid Services

42 CFR Part 414

[CMS–5538–N]

Medicare Program; Alternative Payment Model (APM) Incentive Payment Advisory for Clinicians—Request for Current Billing Information for Qualifying APM Participants

AGENCY: Centers for Medicare & Medicaid Services (CMS), Health and Human Services (HHS).

ACTION: Payment advisory.

SUMMARY: This advisory is to alert certain clinicians who are Qualifying APM participants (QPs) and eligible to receive an Alternative Payment Model (APM) Incentive Payment that CMS does not have the current billing information needed to disburse the payment. This advisory provides information to these clinicians on how to update their billing information to receive this payment.

DATES: Updated billing information must be received no later than September 1, 2023 (see **SUPPLEMENTARY INFORMATION** for details).

FOR FURTHER INFORMATION CONTACT: Tanya Dorm, (410) 786–2216.

SUPPLEMENTARY INFORMATION:

I. Background

Under the Medicare Quality Payment Program, an eligible clinician who participates in an Advanced Alternative Payment Model (APM) and meets the applicable payment amount or patient count thresholds for a performance year is a Qualifying APM Participant (QP) for that year. For payment years 2019 through 2024, which corresponds to Performance Periods for 2017 through 2022, an eligible clinician who is a QP for a year based on their performance in a QP Performance Period earns a 5 percent lump sum APM Incentive Payment that is paid in a payment year that occurs 2 years after the QP Performance Period. The amount of the APM Incentive Payment is equal to 5 percent of the estimated aggregate paid amounts for covered professional services furnished by the QP during the calendar year immediately preceding the payment year.

II. Provisions of the Advisory

The Centers for Medicare & Medicaid Services (CMS) has identified those eligible clinicians who earned an APM Incentive Payment for the calendar year (CY) 2023 payment year based on their QP status for the 2021 QP performance period.

When CMS disbursed the CY 2023 APM Incentive Payments, CMS was unable to verify current Medicare billing information for some QPs and was therefore unable to issue payment. In order to successfully disburse the APM Incentive Payment, CMS is requesting assistance in identifying current Medicare billing information for these QPs in accordance with 42 CFR 414.1450(c)(8).

CMS has compiled a list of QPs we have identified as having unverified billing information. These QPs, and any others who anticipated receiving an APM Incentive Payment but have not, should follow the instructions to provide CMS with updated billing information at the following web address: *https://qpp.cms.gov/resources/resource-library.*

If you have any questions concerning submission of information through the website, please contact the Quality Payment Program Help Desk at 1–866–288–8292.

All submissions must be received no later than September 1, 2023. After that time, any claims to an APM Incentive Payment for the CY 2023 payment period based on an eligible clinicians' QP status for the 2021 QP performance period will be forfeited.

All submissions received by September 1, 2023, will be processed together on one date as soon as practicable after September 1, 2023. CMS will not notify the submitter if we are unable to process the APM Incentive Payment based on the billing information submitted for an eligible clinician.

The Administrator of the Centers for Medicare & Medicaid Services (CMS), Chiquita Brooks-LaSure, having reviewed and approved this document, authorizes Evell J. Barco Holland, who is the Federal Register Liaison, to electronically sign this document for purposes of publication in the **Federal Register**.

Dated: July 25, 2023.

Evell J. Barco Holland,

Federal Register Liaison, Centers for Medicare & Medicaid Services.

BILLING CODE 4120–01–P

Motion to Stay, *United States Steel Corporation v. EPA, et al.*, Case No. 23-1207 (D.C. Cir.)

Exhibit I

Notice of Forthcoming EPA Action to Address Additional Stay Orders (Aug. 2, 2023)

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

August 2, 2023

OFFICE OF
AIR AND RADIATION

MEMORANDUM

SUBJECT: Notice of Forthcoming EPA Action to Address Additional Judicial Stay Orders

FROM: Joseph Goffman
Principal Deputy Assistant Administrator
Office of Air and Radiation

On February 13, 2023, EPA published a final action fully or partially disapproving state implementation plans (SIPs) submitted by 21 states to address the states' obligations under Clean Air Act section 110(a)(2)(D)(i)(I), commonly referred to as the "good neighbor" provision, with respect to the 2015 national ambient air quality standards (NAAQS) for ozone (the SIP Disapproval Action).[1] Consistent with EPA's obligation under Clean Air Act section 110(c)(1), following the SIP Disapproval action the EPA Administrator signed a separate final action, the "Good Neighbor Plan," establishing federal implementation plan requirements to address the states' good neighbor obligations.[2] The Good Neighbor Plan's requirements are scheduled to take effect on August 4, 2023, 60 days after the date of that rule's publication in the *Federal Register*.

After signature of the Good Neighbor Plan, courts granted motions for partial stays of the SIP Disapproval Action with respect to several states. To comply with those orders, on June 29, 2023, the EPA Administrator signed another final action: the Interim Final Rule.[3] In compliance with the courts' decisions, this rule stays the effectiveness of the Good Neighbor Plan's requirements on an interim basis for emissions sources in Arkansas, Kentucky, Louisiana, Mississippi, Missouri, and Texas. This rule also ensures continued implementation of previously established requirements for sources in these states to mitigate interstate air pollution with respect to other ozone NAAQS while the Good Neighbor Plan's requirements are stayed.

---

[1] Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 FR 9336 (February 13, 2023).
[2] Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality Standards, 88 FR 36654 (June 5, 2023).
[3] Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality Standards; Response to Judicial Stays of SIP Disapproval Action for Certain States, 88 FR 49295 (July 31, 2023).

Since signature of the Interim Final Rule, courts have granted additional motions for partial stays of the SIP Disapproval Action as to Minnesota,[4] Nevada,[5] Oklahoma, and Utah.[6] To comply with these additional orders, EPA will take action in the near future to extend the Interim Final Rule to stay the effectiveness of the Good Neighbor Plan's requirements for sources in Minnesota, Nevada, Oklahoma, and Utah while the orders partially staying the SIP Disapproval Action with respect to these states remain in place, and sources in these states are not required to comply with the Good Neighbor Plan at this time.

Motions for partial stays of the SIP Disapproval Action regarding additional states remain pending in other courts. If those courts grant such motions, EPA will extend the Interim Final Rule to ensure that the Good Neighbor Plan's requirements are not effective for sources in any additional state where EPA lacks federal implementation authority because of a stay order, and sources in such states would likewise not be required to comply with the Good Neighbor Plan.

EPA plans to take action extending the Interim Final Rule once all pending motions for partial stays are resolved. This action will make clear that the status quo is maintained as to all such states. To the extent that sources in a given state are covered by previously established requirements to mitigate interstate air pollution with respect to other ozone NAAQS, EPA also intends to apply the provisions of the Interim Final Rule to the sources as needed to ensure that implementation of the previously established requirements continues while the effectiveness of the Good Neighbor Plan's requirements is stayed.

Exhibit J

Air Plan Approval; Wyoming; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 Fed. Reg. 54,998 (Aug. 14, 2023)

IV. Incorporation by Reference

In this rule, EPA is proposing to include in a final EPA rule regulatory text that includes incorporation by reference. In accordance with requirements of 1 CFR 51.5, EPA is proposing to incorporate by reference certain provisions of the Ohio Division of Air Pollution Control Permit-to-Install and Operate for Forest City Technologies Plant 4, effective June 23, 2020, as described in Section III. of this preamble. EPA has made, and will continue to make, these documents generally available through *www.regulations.gov* and at the EPA Region 5 Office (please contact the person identified in the **FOR FURTHER INFORMATION CONTACT** section of this preamble for more information).

V. Statutory and Executive Order Reviews

Under the CAA, the Administrator is required to approve a SIP submission that complies with the provisions of the CAA and applicable Federal regulations. 42 U.S.C. 7410(k); 40 CFR 52.02(a). Thus, in reviewing SIP submissions, EPA's role is to approve state choices, provided that they meet the criteria of the CAA. Accordingly, this action merely approves state law as meeting Federal requirements and does not impose additional requirements beyond those imposed by state law. For that reason, this action:

- Is not a significant regulatory action subject to review by the Office of Management and Budget under Executive Orders 12866 (58 FR 51735, October 4, 1993), 13563 (76 FR 3821, January 21, 2011), and 14094 (88 FR 21879, April 11, 2023);
- Does not impose an information collection burden under the provisions of the Paperwork Reduction Act (44 U.S.C. 3501 *et seq.*);
- Is certified as not having a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*);
- Does not contain any unfunded mandate or significantly or uniquely affect small governments, as described in the Unfunded Mandates Reform Act of 1995 (Pub. L. 104–4);
- Does not have federalism implications as specified in Executive Order 13132 (64 FR 43255, August 10, 1999);
- Is not subject to Executive Order 13045 (62 FR 19885, April 23, 1997) because it approves a state program;
- Is not a significant regulatory action subject to Executive Order 13211 (66 FR 28355, May 22, 2001); and
- Is not subject to requirements of section 12(d) of the National Technology Transfer and Advancement Act of 1995 (15 U.S.C. 272 note) because application of those requirements would be inconsistent with the CAA.

In addition, the SIP is not approved to apply on any Indian reservation land or in any other area where EPA or an Indian tribe has demonstrated that a tribe has jurisdiction. In those areas of Indian country, the rule does not have Tribal implications and will not impose substantial direct costs on Tribal governments or preempt Tribal law as specified by Executive Order 13175 (65 FR 67249, November 9, 2000).

Executive Order 12898 (Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations, 59 FR 7629, February 16, 1994) directs Federal agencies to identify and address ''disproportionately high and adverse human health or environmental effects'' of their actions on minority populations and low-income populations to the greatest extent practicable and permitted by law. EPA defines environmental justice (EJ) as ''the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies.'' EPA further defines the term fair treatment to mean that ''no group of people should bear a disproportionate burden of environmental harms and risks, including those resulting from the negative environmental consequences of industrial, governmental, and commercial operations or programs and policies.''

OEPA did not evaluate environmental justice considerations as part of its SIP submittal; the CAA and applicable implementing regulations neither prohibit nor require such an evaluation. EPA did not perform an EJ analysis and did not consider EJ in this action. Consideration of EJ is not required as part of this action, and there is no information in the record inconsistent with the stated goal of E.O. 12898 of achieving environmental justice for people of color, low-income populations, and Indigenous peoples.

Air Plan Approval; Wyoming; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule and withdrawal of proposed rule.

SUMMARY: Pursuant to the Federal Clean Air Act (CAA or the Act), the Environmental Protection Agency (EPA) is proposing to approve the portion of a Wyoming State Implementation Plan (SIP) submission addressing interstate transport for the 2015 8-hour ozone national ambient air quality standards (NAAQS). EPA is also withdrawing our prior May 24, 2022 proposed disapproval of the interstate transport portion of the Wyoming SIP submission. The ''good neighbor'' or ''interstate transport'' provision requires that each state's SIP contain adequate provisions to prohibit emissions from within the state from significantly contributing to nonattainment or interfering with maintenance of the NAAQS in other states. This requirement is part of the broader set of ''infrastructure'' requirements, which are designed to ensure that the structural components of each state's air quality management program are adequate to meet the state's responsibilities under the CAA.

DATES: Written comments must be received on or before September 13, 2023. As of August 14, 2023, the proposed rule published on May 24, 2022, at 87 FR 31495, is withdrawn.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–R08–OAR–2023–0375, to the Federal Rulemaking Portal: *https://www.regulations.gov.* Follow the online instructions for submitting comments. Once submitted, comments cannot be edited or removed from *www.regulations.gov.* EPA may publish any comment received to its public docket. Do not submit electronically any information you consider to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Multimedia submissions (audio, video, etc.) must be accompanied by a written comment. The written comment is considered the official comment and should include discussion of all points you wish to make. EPA will generally not consider comments or comment contents located outside of the primary submission (*i.e.,* on the web, cloud, or other file sharing system). For additional submission methods, the full EPA public comment policy, information about CBI or multimedia submissions, and general guidance on making effective comments, please visit *https://www2.epa.gov/dockets/commenting-epa-dockets.*

Docket: There are two dockets supporting this action, EPA–R08–OAR–2023–0375 and EPA–HQ–OAR–2021–0663. Docket No. EPA–R08–OAR–2023–0375 contains information specific to Wyoming, including the notice of proposed rulemaking. Docket No. EPA–HQ–OAR–2021–0663 contains additional modeling files, emissions inventory files, technical support documents, and other relevant supporting documentation regarding interstate transport of emissions for the 2015 8-hour ozone NAAQS which are being used to support this action. All comments regarding information in either of these dockets are to be made in Docket No. EPA–R08–OAR–2023–0375. All documents in the docket are listed in the *www.regulations.gov* index. Although listed in the index, some information is not publicly available, *e.g.,* CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, will be publicly available only in hard copy. Publicly available docket materials are available electronically in *www.regulations.gov.*

SUPPLEMENTARY INFORMATION:
Throughout this document whenever ''we,'' ''us,'' or ''our'' is used, we mean EPA.

Table of Contents

I. Background

A. Description of Statutory Background

On October 1, 2015, EPA promulgated a revision to the ozone NAAQS (2015 8-hour ozone NAAQS), lowering the level of both the primary and secondary standards to 0.070 parts per million (ppm) for the 8-hour standard.[1] Section 110(a)(1) of the CAA requires states to submit, within 3 years after promulgation of a new or revised standard, SIP submissions meeting the applicable requirements of section 110(a)(2).[2] One of these applicable requirements is found in CAA section 110(a)(2)(D)(i)(I), otherwise known as the ''interstate transport'' or ''good neighbor'' provision, which generally requires SIPs to contain adequate provisions to prohibit in-state emissions activities from having certain adverse air quality effects on other states due to interstate transport of pollution. There are two so-called ''prongs'' within CAA section 110(a)(2)(D)(i)(I). A SIP for a new or revised NAAQS must contain adequate provisions prohibiting any source or other type of emissions activity within the state from emitting air pollutants in amounts that will significantly contribute to nonattainment of the NAAQS in another state (prong 1) or interfere with maintenance of the NAAQS in another state (prong 2). EPA and states must give independent significance to prong 1 and prong 2 when evaluating downwind air quality problems under CAA section 110(a)(2)(D)(i)(I).[3]

B. Description of EPA's 4-Step Interstate Transport Regulatory Process

EPA is using the 4-step interstate transport framework (or 4-step framework) to evaluate Wyoming's January 3, 2019 SIP submission addressing interstate transport for the 2015 ozone NAAQS. EPA has addressed the interstate transport requirements of CAA section 110(a)(2)(D)(i)(I) with respect to prior NAAQS in several regulatory actions, including the Cross-State Air Pollution Rule (CSAPR), which addressed interstate transport with respect to the 1997 ozone NAAQS as well as the 1997 and 2006 fine particulate matter standards,[4] the Cross-State Air Pollution Rule Update (CSAPR Update)[5] and the Revised Cross-State Air Pollution Rule Update (Revised CSAPR Update),[6] both of which addressed the 2008 ozone NAAQS.[7]

Shaped through the years by input from state air agencies[8] and other stakeholders on EPA's prior interstate transport rulemakings and SIP actions,[9] as well as a number of court decisions, EPA has developed and used the following 4-step interstate transport framework to evaluate a state's obligations to eliminate interstate transport emissions under the interstate transport provision for the ozone NAAQS: (1) identify monitoring sites that are projected to have problems attaining and/or maintaining the NAAQS (*i.e.,* nonattainment and/or maintenance receptors); (2) identify

---

[1] National Ambient Air Quality Standards for Ozone, Final Rule, 80 FR 65292 (October 26, 2015). Although the level of the standard is specified in the units of ppm, ozone concentrations are also described in parts per billion (ppb). For example, 0.070 ppm is equivalent to 70 ppb.

[2] SIP revisions that are intended to meet the applicable requirements of section 110(a)(1) and (2) of the CAA are often referred to as infrastructure SIPs and the applicable elements under section 110(a)(2) are referred to as infrastructure requirements.

[3] *See North Carolina* v. *EPA,* 531 F.3d 896, 909–11 (D.C. Cir. 2008).

[4] Federal Implementation Plans: Interstate Transport of Fine Particulate Matter and Ozone and Correction of SIP Approvals, 76 FR 48208 (Aug. 8, 2011).

[5] Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS, 81 FR 74504 (Oct. 26, 2016).

[6] Revised Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS, 86 FR 23054 (April 30, 2021).

[7] In 2019, the D.C. Circuit Court of Appeals remanded the CSAPR Update to the extent it failed to require upwind states to eliminate their significant contribution by the next applicable attainment date by which downwind states must come into compliance with the NAAQS, as established under CAA section 181(a). *Wisconsin* v. *EPA,* 938 F.3d 303, 313 (D.C. Cir. 2019). The Revised CSAPR Update for the 2008 Ozone NAAQS, 86 FR 23054 (April 30, 2021), responded to the remand of the CSAPR Update in *Wisconsin* and the vacatur of a separate rule, the ''CSAPR Close-Out,'' 83 FR 65878 (December 21, 2018), in *New York* v. *EPA,* 781 F. App'x. 4 (D.C. Cir. 2019). The Revised CSAPR Update was upheld in *Midwest Ozone Group* v. *EPA,* 61 F.4th 187 (D.C. Cir. 2023).

[8] *See* 63 FR 57356, 57361 (October 27, 1998).

[9] In addition to CSAPR rulemakings, other regional rulemakings addressing ozone transport include the ''NO_X SIP Call,'' 63 FR 57356 (October 27, 1998), and the ''Clean Air Interstate Rule'' (CAIR), 70 FR 25162 (May 12, 2005).

states that impact those air quality problems in other (*i.e.,* downwind) states sufficiently such that the states are considered ''linked'' and therefore warrant further review and analysis; (3) identify the emissions reductions necessary (if any), applying a multifactor analysis, to eliminate each linked upwind state's significant contribution to nonattainment or interference with maintenance of the NAAQS at the locations identified in Step 1; and (4) adopt permanent and enforceable measures needed to achieve those emissions reductions.

C. Background on EPA's Ozone Transport Modeling Information

In general, EPA has performed nationwide air quality modeling to project ozone design values which are used in combination with measured data to identify nonattainment and maintenance receptors at Step 1. To quantify the contribution of emissions from individual upwind states on 2023 ozone design values for the identified downwind nonattainment and maintenance receptors at Step 2, EPA has performed multiple iterations of nationwide, state-level ozone source apportionment modeling for 2023. The source apportionment modeling projected contributions to ozone at receptors from precursor emissions of anthropogenic nitrogen oxides (NO_X) and volatile organic compounds (VOCs) in individual upwind states.

EPA has released several documents containing projected ozone design values, contributions, and information relevant to air agencies for evaluation of interstate transport with respect to the 2015 ozone NAAQS. First, on January 6, 2017, EPA published a notice of data availability (NODA) in which the Agency requested comment on preliminary interstate ozone transport data including projected ozone design values and interstate contributions for 2023 using a 2011 base year platform.[10] In the NODA, EPA used the year 2023 as the analytic year for this preliminary modeling because this year aligns with the expected attainment year for Moderate ozone nonattainment areas for the 2015 8-hour ozone NAAQS.[11] On October 27, 2017, EPA released a memorandum (October 2017 memorandum) containing updated modeling data for 2023, which incorporated changes made in response to comments on the NODA, and was intended to provide information to assist states' efforts to develop SIP submissions to address interstate transport obligations for the 2008 ozone NAAQS.[12] On March 27, 2018, EPA issued a memorandum (March 2018 memorandum) noting that the same 2023 modeling data released in the October 2017 memorandum could also be useful for identifying potential downwind air quality problems with respect to the 2015 ozone NAAQS at Step 1 of the 4-step interstate transport framework.[13] The March 2018 memorandum also included the then newly available contribution modeling data for 2023 to assist states in evaluating their impact on potential downwind air quality problems for the 2015 8-hour ozone NAAQS under Step 2 of the 4-step interstate transport framework.[14] EPA notes that the State of Wyoming relied upon 2023 modeling contribution data released with the March 2018 memorandum in developing its 2019 SIP submission. EPA subsequently issued two more memoranda in August and October 2018, providing additional information to states developing interstate transport SIP submissions for the 2015 ozone NAAQS concerning, respectively, potential contribution thresholds that may be appropriate to apply in Step 2 of the 4-step interstate transport framework, and considerations for identifying downwind areas that may have problems maintaining the standard at Step 1 of the 4-step interstate transport framework.[15]

Following the release of the modeling data shared in the March 2018 memorandum, EPA performed updated modeling using a 2016-based emissions modeling platform (*i.e.,* 2016v1). This emissions platform was developed under the EPA/Multi-Jurisdictional Organization (MJO)/state collaborative project.[16] This collaborative project was a multi-year joint effort by EPA, MJOs, and states to develop a new, more recent emissions platform for use by EPA and states in regulatory modeling as an improvement over the dated 2011-based platform that EPA had used to project ozone design values and contribution data provided in the 2017 and 2018 memoranda. EPA used the 2016v1 emissions to project ozone design values and contributions for 2023. On October 30, 2020, in the notice of proposed rulemaking for the Revised CSAPR Update, EPA released and accepted public comment on 2023 modeling that used the 2016v1 emissions platform.[17] Although the Revised CSAPR Update addressed transport for the 2008 ozone NAAQS, the projected design values and contributions from the 2016v1 platform were also useful for identifying downwind ozone problems and linkages with respect to the 2015 ozone NAAQS.[18]

Following the final Revised CSAPR Update, EPA made further updates to the 2016-based emissions platform to include updated onroad mobile emissions from Version 3 of EPA's Motor Vehicle Emission Simulator (MOVES) model (MOVES3)[19] and updated emissions projections for electric generating units (EGUs) that reflected the emissions reductions from the Revised CSAPR Update, recent information on plant closures, and other inventory improvements. EPA published these emissions inventories on its website in September of 2021 and invited initial feedback from states and other interested stakeholders.[20] The construct of the updated emissions platform, 2016v2, is described in the

[18] See the Air Quality Modeling Technical Support Document for the Final Revised Cross-State Air Pollution Rule Update, included in the Headquarters docket ID No. EPA–HQ–OAR–2021–0663.

[19] Additional details and documentation related to the MOVES3 model can be found at *https://www.epa.gov/moves/latest-version-motor-vehicle-emission-simulator-moves.*

[20] *https://www.epa.gov/air-emissions-modeling/2016v2-platform.*

''Technical Support Document (TSD): Preparation of Emissions Inventories for the 2016v2 North American Emissions Modeling Platform,'' hereafter known as the 2016v2 Emissions Modeling TSD, and is included in Docket No. EPA–HQ–OAR–2021–0663. The EPA performed air quality modeling using the 2016v2 emissions to provide projections of ozone design values and contributions in 2023 and 2026 that reflect the effects on air quality of the 2016v2 emissions platform. EPA used the results of the 2016v2 modeling as part of our previous proposed evaluation of the Wyoming 2019 SIP submission with respect to Steps 1 and 2 of the 4-step interstate transport framework. *See* 87 FR 31495 (May 24, 2022).

EPA invited and received comments on the 2016v2 emissions inventories and modeling used to support proposals, including the proposal on Wyoming, related to interstate transport under the 2015 ozone NAAQS. In response to these comments, EPA made a number of updates to the 2016v2 inventories and model design to construct a 2016v3 emissions platform which was used to update the air quality modeling. EPA used this updated modeling to inform a final rulemaking taking final action on 21 interstate transport SIP submissions for the 2015 ozone NAAQS, which did not include Wyoming.[21] Details on the 2016v3 air quality modeling and the methods for projecting design values and determining contributions in 2023 and 2026 are described in the TSD titled ''Air Quality Modeling Final Rule TSD—2015 Ozone NAAQS Good Neighbor Plan,'' hereafter known as the Final Good Neighbor Plan AQM TSD.[22] Additional details related to the updated 2016v3 emissions platform are located in the TSD titled ''Preparation of Emissions Inventories for the 2016v3 North American Emissions Modeling Platform,'' hereafter known as the 2016v3 Emissions Modeling TSD, included in Docket ID No. EPA–HQ–OAR–2021–0663.[23]

In this proposed action, EPA primarily relies on modeling based on the updated 2016v3 emissions platform in evaluating Wyoming's 2019 submission with respect to Steps 1 and 2 of the 4-step interstate transport framework, which will generally be referenced within this action as the ''2016v3 modeling'' for 2023 and 2026. By using the updated modeling results, EPA is using the most current and technically appropriate information for this proposed rulemaking. In this proposed action, EPA is accepting public comment on the 2016v3 modeling solely as it relates to Wyoming's interstate transport obligations for the 2015 ozone NAAQS. EPA is not reopening the modeling in relation to any other state or regulatory action. Any comments received on the modeling that are not relevant to the evaluation of Wyoming's interstate-transport obligations will be treated as beyond the scope of this action.

D. EPA's Approach to Evaluating Interstate Transport SIPs for the 2015 Ozone NAAQS

EPA proposes to apply a consistent set of policy judgments across all states for purposes of evaluating interstate transport obligations and the approvability of interstate transport SIP submissions for the 2015 ozone NAAQS under CAA section 110(a)(2)(D)(i)(I). These policy judgments conform with relevant case law and past agency practice as reflected in CSAPR and related rulemakings. Employing a nationally consistent approach is particularly important in the context of interstate ozone transport, which is a regional-scale pollution problem involving many smaller contributors. Effective policy solutions to the problem of interstate ozone transport going back to the NO_X SIP Call have necessitated the application of a uniform framework of policy judgments in order to ensure an ''efficient and equitable'' approach. *See EME Homer City Generation, LP* v. *EPA,* 572 U.S. 489, 519 (2014).

The remainder of this section describes EPA's analytic framework with respect to analytic year, definition of nonattainment and maintenance receptors, selection of contribution threshold, and multifactor control strategy assessment.

1. Selection of Analytic Year

In general, the states and EPA must implement the interstate transport provision in a manner ''consistent with the provisions of [title I of the CAA.]'' *See* CAA section 110(a)(2)(D)(i). This requires, among other things, that these obligations are addressed consistently with the timeframes for downwind areas to meet their CAA obligations. With respect to ozone NAAQS, under CAA section 181(a), this means obligations must be addressed ''as expeditiously as practicable'' and no later than the schedule of attainment dates provided in CAA section 181(a)(1).[24] Several D.C. Circuit court decisions address the issue of the relevant analytic year for the purposes of evaluating ozone transport air-quality problems. On September 13, 2019, the D.C. Circuit issued a decision in *Wisconsin,* remanding the CSAPR Update to the extent that it failed to require upwind states to eliminate their significant contribution by the next applicable attainment date by which downwind states must come into compliance with the NAAQS, as established under CAA section 181(a). *See* 938 F.3d 303, 313.

On May 19, 2020, the D.C. Circuit issued a decision in *Maryland* v. *EPA* that cited the *Wisconsin* decision in holding that EPA must assess the impact of interstate transport on air quality at the next downwind attainment date, including Marginal area attainment dates, in evaluating the basis for EPA's denial of a petition under CAA section 126(b) *Maryland* v. *EPA,* 958 F.3d 1185, 1203–04 (D.C. Cir. 2020) (*Maryland*). The court noted that ''section 126(b) incorporates the Good Neighbor Provision,'' and, therefore, ''EPA must find a violation [of section 126] if an upwind source will significantly contribute to downwind nonattainment at the *next downwind attainment deadline.* Therefore, the agency must evaluate downwind air quality at that deadline, not at some later date.'' *Id.* at 1204 (emphasis added). EPA interprets the court's holding in *Maryland* as requiring the states and the Agency, under the good neighbor provision, to assess downwind air quality as expeditiously as practicable and no later than the next applicable attainment date,[25] which is currently the 2015 ozone NAAQS Moderate area attainment date of August 3, 2024 under CAA section 181 for ozone nonattainment.[26] Thus, 2023 remains

[21] ''Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards,'' 88 FR 9336 (February 13, 2023), and ''Federal ''Good Neighbor Plan'' for the 2015 Ozone National Ambient Air Quality Standards,'' 88 FR 36654 (June 5, 2023).

[22] Air Quality Modeling Final Rule Technical Support Document—2015 Ozone NAAQS Good Neighbor Plan in Docket ID No. EPA–R08–OAR–2023–0375.

[23] 2016v3 Emissions Modeling TSD in Docket ID No. EPA–HQ–OAR–2021–0663.

[24] For attainment dates for the 2015 8-hour ozone NAAQS, refer to CAA section 181(a), 40 CFR 51.1303, and Additional Air Quality Designations for the 2015 Ozone National Ambient Air Quality Standards, 83 FR 25776 (June 4, 2018, effective Aug. 3, 2018).

[25] We note that the court in *Maryland* did not have occasion to evaluate circumstances in which EPA may determine that an upwind linkage to a downwind air quality problem exists at steps 1 and 2 of the interstate transport framework by a particular attainment date, but for reasons of impossibility or profound uncertainty the Agency is unable to mandate upwind pollution controls by that date. *See Wisconsin,* 938 F.3d at 320. The D.C. Circuit noted in *Wisconsin* that upon a sufficient showing, these circumstances may warrant flexibility in effectuating the purpose of the interstate transport provision.

[26] *See* CAA section 181(a); 40 CFR 51.1303; Additional Air Quality Designations for the 2015

Continued

the appropriate year for analysis of interstate transport obligations for the 2015 ozone NAAQS because the 2023 ozone season is the last relevant ozone season during which achieved emissions reductions in linked upwind states could assist downwind states with meeting the August 3, 2024 Moderate area attainment date for the 2015 ozone NAAQS.

EPA recognizes that the attainment date for nonattainment areas classified as Marginal for the 2015 ozone NAAQS was August 3, 2021. Under the *Maryland* holding, any necessary emissions reductions to satisfy interstate transport obligations should have been implemented by no later than this date. At the time of the statutory deadline to submit interstate transport SIPs (October 1, 2018), many states relied on EPA's modeling of the year 2023, and no state provided an alternative analysis using a 2021 analytic year (or the prior 2020 ozone season). However, EPA must act on SIP submissions using the information available at the time it takes such action. In this circumstance, EPA does not believe it would be appropriate to evaluate states' obligations under CAA section 110(a)(2)(D)(i)(I) as of an attainment date that is wholly in the past, because the Agency interprets the interstate transport provision as forward looking. *See* 86 FR 23074; *see also Wisconsin,* 938 F.3d at 322 (rejecting Delaware's argument that EPA should have used an analytic year of 2011 instead of 2017). Consequently, in this proposal EPA will use the analytical year of 2023 to evaluate Wyoming's CAA section 110(a)(2)(D)(i)(I) SIP submission with respect to the 2015 ozone NAAQS.[27]

2. Step 1 of the 4-Step Interstate Transport Framework

In Step 1, EPA identifies monitoring sites that are projected to have problems attaining and/or maintaining the NAAQS in the 2023 analytic year. Where EPA's analysis shows that a site does not fall under the definition of a nonattainment or maintenance receptor, that site is excluded from further analysis under EPA's 4-step interstate transport framework. For sites that are identified as a nonattainment or maintenance receptor in 2023, EPA proceeds to the next step of the 4-step interstate transport framework by identifying which upwind states contribute to those receptors above the contribution threshold.

EPA's approach to identifying ozone nonattainment and maintenance receptors in this action gives independent consideration to both the ''contribute significantly to nonattainment'' and the ''interfere with maintenance'' prongs of CAA section 110(a)(2)(D)(i)(I), consistent with the D.C. Circuit's direction in *North Carolina*.[28]

EPA identifies nonattainment receptors as those monitoring sites that are projected to have average design values that exceed the NAAQS and that are also measuring nonattainment based on the most recent monitored design values. This approach is consistent with prior transport rulemakings, such as the CSAPR Update, where EPA defined nonattainment receptors as those areas that both currently measure nonattainment and that EPA projects will be in nonattainment in the analytic year (*i.e.,* 2023).[29]

In addition, in this proposal, EPA identifies a receptor to be a ''maintenance'' receptor for purposes of defining interference with maintenance, consistent with the method used in CSAPR and upheld by the D.C. Circuit in *EME Homer City Generation, L.P.* v. *EPA,* 795 F.3d 118, 136 (D.C. Cir. 2015) (*EME Homer City II*).[30] Specifically, EPA identified maintenance receptors as those receptors that would have difficulty maintaining the relevant NAAQS in a scenario that takes into account historical variability in air quality at that receptor. The variability in air quality was determined by evaluating the ''maximum'' future design value at each receptor based on a projection of the maximum measured design value over the relevant period. EPA interprets the projected maximum future design value to be a potential future air quality outcome consistent with the meteorology that yielded maximum measured concentrations in the ambient data set analyzed for that receptor (*i.e.,* ozone conducive meteorology). EPA also recognizes that previously experienced meteorological conditions (*e.g.,* dominant wind direction, temperatures, and air mass patterns) promoting ozone formation that led to maximum concentrations in the measured data may reoccur in the future. The maximum design value gives a reasonable projection of future air quality at the receptor under a scenario in which such conditions do, in fact, reoccur. The projected maximum design value is used to identify upwind emissions that, under those circumstances, could interfere with the downwind area's ability to maintain the NAAQS.

Nonattainment receptors are also, by definition, maintenance receptors, and so EPA often uses the term ''maintenance-only'' to refer to those receptors that are not nonattainment receptors. Consistent with the concepts for maintenance receptors, as described earlier, EPA identifies ''maintenance-only'' receptors as those monitoring sites that have projected average design values above the level of the applicable NAAQS, but that are not currently measuring nonattainment based on the most recent official design values.[31] In addition, those monitoring sites with projected average design values below the NAAQS, but with projected maximum design values above the NAAQS are also identified as ''maintenance-only'' receptors, even if they are currently measuring nonattainment based on the most recent official design values.

Ozone National Ambient Air Quality Standards, 83 FR 25776 (June 4, 2018, effective Aug. 3, 2018).

[27] EPA recognizes that by the time final action is taken with respect to this SIP submission, the 2023 ozone season will likely be wholly in the past. However, as discussed in section III., the available modeling information indicates that our analysis would not change as to Wyoming for any later year.

[28] *See North Carolina* v. *EPA,* 531 F.3d at 910–11 (holding that the EPA must give ''independent significance'' to each prong of CAA section 110(a)(2)(D)(i)(I)).

[29] *See* 81 FR 74504 (October 26, 2016). This same concept, relying on both current monitoring data and modeling to define nonattainment receptor, was also applied in CAIR. *See* 70 FR 25241, 25249 (January 14, 2005); *see also North Carolina,* 531 F.3d at 913–14 (affirming as reasonable EPA's approach to defining nonattainment in CAIR).

[30] *See* 76 FR 48208 (August 8, 2011). CSAPR Update and Revised CSAPR Update also used this approach. See 81 FR 74504 (October 26, 2016) and 86 FR 23054 (April 30, 2021).

[31] The Agency often uses the terms maintenance receptor and maintenance-only receptor interchangeably when discussing maintenance receptors that are not also nonattainment receptors.

The Agency has also taken a closer look at measured ozone levels at monitoring sites in 2021 and 2022 for the purposes of informing the identification of additional receptors in 2023. As explained in more detail in the February 13, 2022 final action disapproving 19 states' good neighbor SIP submissions, and partially approving and partially disapproving 2 states' good neighbor SIP submissions, *see* 88 FR 9349–50, we find there is a basis to consider certain sites with elevated ozone levels that are not otherwise identified as receptors to be an additional type of maintenance-only receptor given the likelihood that ozone levels above the NAAQS could persist at those locations through at least 2023. We refer to these as violating-monitor maintenance-only receptors (''violating monitors''). In this action, EPA proposes to use certified monitoring data as an additional method to identify maintenance-only receptors. In the case of Wyoming, this analysis confirms that the state is not projected to be linked to any violating-monitor receptors. EPA is not reopening this methodology, except to the extent of its application to Wyoming, nor in relation to the evaluation of any other state's good neighbor obligations for the 2015 ozone NAAQS. Any such comments on those topics will be treated as beyond the scope of this action.

3. Step 2 of the 4-Step Interstate Transport Framework

In Step 2 EPA quantifies the contribution of each upwind state to each receptor in the 2023 analytic year. The contribution metric used in Step 2 is defined as the average impact from each state to each receptor on the days with the highest ozone concentrations at the receptor based on the 2023 modeling. If a state's contribution value does not equal or exceed the threshold of 1 percent of the NAAQS (*i.e.,* 0.70 ppb for the 2015 ozone NAAQS), the upwind state is not ''linked'' to a downwind air quality problem, and EPA therefore concludes that the state does not contribute significantly to nonattainment or interfere with maintenance of the NAAQS in the downwind states. However, if a state's contribution equals or exceeds the 1 percent threshold, the state's emissions are further evaluated in Step 3, considering both air quality and cost as part of a multi-factor analysis, to determine what, if any, emissions might be deemed ''significant'' and, thus, must be eliminated pursuant to the requirements of CAA section 110(a)(2)(D)(i)(I).

In this proposed action, EPA relies in the first instance on the 1 percent of the NAAQS threshold for the purpose of evaluating a state's contribution to nonattainment or maintenance of the 2015 ozone NAAQS at downwind receptors. This is consistent with the Step 2 approach that EPA applied in CSAPR for the 1997 ozone NAAQS, which has subsequently been applied in the CSAPR Update and Revised CSAPR Update when evaluating interstate transport obligations for the 2008 ozone NAAQS. EPA continues to find 1 percent of the NAAQS to be an appropriate threshold. For ozone, as EPA found in the CAIR, CSAPR, and CSAPR Update, a portion of the nonattainment problems from anthropogenic sources in the U.S. results from the combined impact of relatively small contributions, typically from multiple upwind states and, in some cases, substantially larger contributions from a subset of particular upwind states, along with contributions from in-state sources. EPA's analysis shows that much of the ozone transport problem in the United States is still the result of the collective impacts of contributions from upwind states. Therefore, application of a consistent contribution threshold is necessary to identify those upwind states that should have responsibility for addressing their contribution to the downwind nonattainment and maintenance problems to which they collectively contribute. Continuing to use 1 percent of the NAAQS as the screening metric to evaluate collective contribution from many upwind states also allows EPA (and states) to apply a consistent framework to evaluate interstate emissions transport under the interstate transport provision from one NAAQS to the next. *See* 81 FR 74518*; see also* 86 FR 23085 (reviewing and explaining rationale from CSAPR, 76 FR 48237–38, for selection of 1 percent threshold).

4. Step 3 of the 4-Step Interstate Transport Framework

Consistent with EPA's longstanding approach to eliminating significant contribution and interference with maintenance, at Step 3, a multifactor assessment of potential emissions controls is conducted for states linked at Steps 1 and 2. EPA's analysis at Step 3 in prior Federal actions addressing interstate transport requirements has primarily focused on an evaluation of cost-effectiveness of potential emissions controls (on a marginal cost-per-ton basis), the total emissions reductions that may be achieved by requiring such controls (if applied across all linked upwind states), and an evaluation of the air quality impacts such emissions reductions would have on the downwind receptors to which a state is linked; other factors may potentially be relevant if adequately supported. In general, where EPA's or state-provided alternative air quality and contribution modeling establishes that a state is linked at Steps 1 and 2, it will be insufficient at Step 3 for a state merely to point to its existing rules requiring control measures as a basis for SIP approval. In general, the emissions-reducing effects of all existing emissions control requirements are already reflected in the future year projected air quality results of the modeling for Steps 1 and 2. If the state is shown to still be linked to one or more downwind receptor(s) despite these existing controls, but that state believes it has no outstanding good neighbor obligations, EPA expects the state to provide sufficient justification to support a conclusion by EPA that the state has adequate provisions prohibiting ''any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will'' ''contribute significantly to nonattainment in, or interfere with maintenance by,'' any other state with respect to the NAAQS. *See* CAA section 110(a)(2)(D)(i)(I). While EPA has not prescribed a particular method for this assessment, EPA expects states at a minimum to present a sufficient technical evaluation. This would typically include information on emissions sources, applicable control technologies, emissions reductions, costs, cost effectiveness, and downwind air quality impacts of the estimated reductions, before concluding that no additional emissions controls should be required.[32]

5. Step 4 of the 4-Step Interstate Transport Framework

At Step 4, states (or EPA) develop permanent and federally-enforceable control strategies to achieve the emissions reductions determined to be necessary at Step 3 to eliminate significant contribution to nonattainment or interference with maintenance of the NAAQS. For a state linked at Steps 1 and 2 to rely on an

[32] As examples of general approaches for how such an analysis could be conducted for their sources, states could look to the CSAPR Update, 81 FR 74504, 74539–51; CSAPR, 76 FR 48208, 48246–63; CAIR, 70 FR 25162, 25195–229; or the NO_X SIP Call, 63 FR 57356, 57399–405. *See also* Revised CSAPR Update, 86 FR 23054, 23086–23116. Consistently across these rulemakings, the EPA has developed emissions inventories, analyzed different levels of control stringency at different cost thresholds, and assessed resulting downwind air quality improvements.

emissions control measure at Step 3 to address its interstate transport obligations, that measure must be included in the state's SIP so that it is permanent and federally enforceable. *See* CAA section 110(a)(2)(D) (''Each such [SIP] shall . . . contain adequate provisions . . . .''). *See also* CAA section 110(a)(2)(A); *Committee for a Better Arvin* v. *EPA,* 786 F.3d 1169, 1175–76 (9th Cir. 2015) (holding that measures relied on by a state to meet CAA requirements must be included in the SIP).

II. Wyoming SIP Submission Addressing Interstate Transport of Air Pollution for the 2015 8-Hour Ozone NAAQS

A. Summary of Wyoming's 2015 Ozone Interstate Transport SIP Submission

On January 3, 2019, Wyoming submitted a SIP submission to EPA addressing the infrastructure requirements of CAA section 110(a)(1) and (2), including the CAA section 110(a)(2)(D)(i)(I) interstate transport requirements, for the 2015 8-hour ozone NAAQS.[33] The SIP submission provided Wyoming's analysis of the State's impact to downwind states and concluded that emissions from Wyoming will not significantly contribute to nonattainment or interfere with maintenance of the 2015 ozone NAAQS in other states in 2023.[34] The SIP submission cited EPA's 4-step framework, but also included a ''weight-of-evidence'' analysis.[35] Based on the results of its ''weight-of-evidence'' analysis at Step 2, Wyoming's 2019 SIP submission concluded that emissions from the State are not linked to a downwind projected nonattainment or maintenance receptor and therefore do not contribute to nonattainment or interfere with the maintenance of the 2015 ozone NAAQS in any downwind state.[36]

B. Prior Notices Related to Wyoming's SIP Submission

On May 24, 2022, the EPA proposed disapproval of the portion of Wyoming's January 3, 2019 SIP submission addressing CAA section 110(a)(2)(D)(i)(I) for the 2015 ozone NAAQS. 87 FR 31495. In EPA's proposed disapproval, as part of the evaluation of Wyoming's submission, we considered the most recently updated modeling platform available at the time, 2016v2, which established one linkage from Wyoming to the Douglas County nonattainment receptor in Colorado (Site ID 80350004), with a projected 2023 contribution from Wyoming of 0.81 ppb.[37] When EPA completed updated modeling for 2023 and 2026 using the 2016v3 platform, Wyoming was not projected to be linked to any downwind nonattainment or maintenance-only receptors in 2023, with a maximum projected contribution of 0.68 ppb at the Douglas County nonattainment receptor in 2023.[38] On January 31, 2023, EPA signed a final rulemaking, finalizing disapproval of 19 SIP submissions, and partially approved and partially disapproved two SIP submissions, for inadequately addressing the good neighbor provision for the 2015 ozone NAAQS and noted that EPA was not taking final action at that time on two SIP submissions for which EPA had proposed disapproval, including Wyoming's.[39] Based on the updated modeling using the 2016v3 platform, discussed in section I.C. above, as well as EPA's evaluation in section III. below, EPA is now withdrawing our May 24, 2022 proposed disapproval of the 110(a)(2)(D)(i)(I) portion of Wyoming's January 3, 2019 SIP submission, at 87 FR 31495.

III. EPA's Evaluation

Wyoming's 2019 SIP submission addressing CAA section 110(a)(2)(D)(i)(I) for the 2015 Ozone NAAQS relies on the 4-step framework and the analytic year 2023 contribution modeling results released with the March 2018 memorandum to conclude that Wyoming does not significantly contribute to nonattainment or interfere with maintenance of the 2015 ozone NAAQS in any other state at Step 2 of the 4-step framework.

As described in section I.C. of this proposal, EPA performed air quality modeling to project ozone design values and contributions for 2023 and 2026 using the 2016v3 emissions platform. EPA proposes to rely primarily on this updated modeling in evaluating Wyoming's transport SIP submission. The design values and contributions from the updated modeling were examined to determine if Wyoming contributes at or above the threshold of 1 percent of the 2015 ozone NAAQS (0.70 ppb) to any downwind nonattainment or maintenance receptor.[40] The data[41] indicate that the highest contributions from Wyoming to downwind nonattainment and maintenance-only receptors are 0.68 ppb and 0.67 ppb in 2023, respectively, and 0.40 ppb and 0.59 ppb in 2026, respectively.[42] EPA's evaluation of Wyoming's contributions to violating-monitor maintenance-only receptors indicate the State's maximum contribution is 0.42 ppb in 2023.[43]

EPA's evaluation of measured and monitored data and contribution values in 2023 and 2026 indicates that the contribution to ozone concentrations in other states from emissions in Wyoming will not equal or exceed the contribution threshold of 0.70 ppb. Thus, EPA proposes to find that the State does not impact downwind air quality problems such that it should be considered ''linked'' at Step 2 of the 4-step framework, and therefore does not warrant further review and analysis at Steps 3 and 4. The results of EPA's evaluation are consistent with the conclusion drawn by Wyoming in the 2019 SIP submission that emissions from sources in Wyoming will not contribute to nonattainment or interfere with maintenance of the 2015 ozone NAAQS in any other state. For these reasons, EPA is proposing to approve Wyoming's 2019 SIP submission with regard to the interstate transport requirements of CAA section 110(a)(2)(D)(i)(I).

IV. Proposed Action

Based on EPA's evaluation of the impact of air emissions from Wyoming

[33] *See* Wyoming State Implementation Plan, Interstate Transport, To Satisfy the Requirements of Clean Air Act 110(a)(2)(i)(I) for the 8-Hour Ozone NAAQS Promulgated in October 2015, December 2018, located in the docket for this rulemaking at *regulations.gov,* Docket No. EPA–R08–OAR–2023–0375.

[34] Wyoming State Implementation Plan, Attachment B at 10.

[35] See generally id. at 3–10.

[36] Id. at 9–10.

[37] 87 FR 31505.

[38] *See* Final Good Neighbor Plan AQM TSD in Docket ID No. EPA–R08–OAR–2023–0375.

[39] *See* Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 FR 9336 (February 13, 2023).

[40] EPA need not assess the data and analysis in Wyoming's submission, as EPA's updated modeling corroborates Wyoming's conclusion that the State will not significantly contribute to nonattainment or interfere with maintenance of the 2015 ozone NAAQS in any other state.

[41] Design values and contributions at individual monitoring sites nationwide are provided in the file Final GNP O3 DVs Contributions, which is included in docket ID No. EPA–R08–OAR–2023–0375.

[42] EPA's analysis indicates that in 2023 Wyoming will have a 0.68 ppb impact at the projected nonattainment receptor in Douglas County, Colorado (site ID 80350004), and a 0.67 ppb impact at the projected maintenance-only receptor in Larimer County, Colorado (site ID 80690011). EPA's analysis indicates maximum 2026 Wyoming emission impacts of 0.40 ppb at projected nonattainment receptors in Jefferson County, Colorado (sites 80590006 and 80590011), and 0.59 at a projected maintenance receptor in Larimer County, Colorado (site 80690011).

[43] EPA's analysis indicates that in 2023 Wyoming will have a 0.42 ppb impact at the violating-monitor maintenance-only receptor in Arapahoe County, Colorado (site ID 80050002).

to downwind states using 2023 analytic year modeling as described in this document, EPA is proposing to approve Wyoming's January 3, 2019 SIP submission as meeting the interstate transport requirements of CAA section 110(a)(2)(D)(i)(I) for the 2015 ozone NAAQS. EPA is seeking public comment on the issues discussed in this proposed rule. We will accept comments from the public on this proposal for the next 30 days.

V. Statutory and Executive Order Reviews

Under the CAA, the Administrator is required to approve a SIP submission that complies with the provisions of the Act and applicable Federal regulations. 42 U.S.C. 7410(k); 40 CFR 52.02(a). Thus, in reviewing SIP submissions, the EPA's role is to approve state choices, provided that they meet the criteria of the CAA. Accordingly, this action merely proposes to approve state law as meeting Federal requirements and does not impose additional requirements beyond those imposed by state law. For that reason, this action:

- Is not a ''significant regulatory action'' subject to review by the Office of Management and Budget under Executive Orders 12866 (58 FR 51735, October 4, 1993) and 13563 (76 FR 3821, January 21, 2011);
- Does not impose an information collection burden under the provisions of the Paperwork Reduction Act (44 U.S.C. 3501 *et seq.*);
- Is certified as not having a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*);
- Does not contain any unfunded mandate or significantly or uniquely affect small governments, as described in the Unfunded Mandates Reform Act of 1995 (Pub. L. 104–4);
- Does not have federalism implications as specified in Executive Order 13132 (64 FR 43255, August 10, 1999);
- Is not an economically significant regulatory action based on health or safety risks subject to Executive Order 13045 (62 FR 19885, April 23, 1997);
- Is not a significant regulatory action subject to Executive Order 13211 (66 FR 28355, May 22, 2001);
- Is not subject to requirements of section 12(d) of the National Technology Transfer and Advancement Act of 1995 (15 U.S.C. 272 note) because application of those requirements would be inconsistent with the CAA; and

In addition, the SIP is not approved to apply on any Indian reservation land or in any other area where EPA or an Indian tribe has demonstrated that a tribe has jurisdiction. In those areas of Indian country, the proposed rule does not have tribal implications and will not impose substantial direct costs on tribal governments or preempt tribal law as specified by Executive Order 13175 (65 FR 67249, November 9, 2000).

Executive Order 12898 (Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations, 59 FR 7629, Feb. 16, 1994) directs Federal agencies to identify and address ''disproportionately high and adverse human health or environmental effects'' of their actions on minority populations and low-income populations to the greatest extent practicable and permitted by law. EPA defines environmental justice (EJ) as ''the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies.'' EPA further defines the term fair treatment to mean that ''no group of people should bear a disproportionate burden of environmental harms and risks, including those resulting from the negative environmental consequences of industrial, governmental, and commercial operations or programs and policies.'' Wyoming did not evaluate environmental justice considerations as part of its SIP submission; the CAA and applicable implementing regulations neither prohibit nor require such an evaluation. EPA did not perform an EJ analysis and did not consider EJ in this action. Consideration of EJ is not required as part of this action, and there is no information in the record inconsistent with the stated goal of E.O. 12898 of achieving environmental justice for people of color, low-income populations, and Indigenous peoples.

Section 307(b)(1) of the CAA governs judicial review of final actions by EPA. This section provides, in part, that petitions for review must be filed in the D.C. Circuit: (i) when the agency action consists of ''nationally applicable regulations promulgated, or final actions taken, by the Administrator,'' or (ii) when such action is locally or regionally applicable, if ''such action is based on a determination of nationwide scope or effect and if in taking such action the Administrator finds and publishes that such action is based on such a determination.'' For locally or regionally applicable final actions, the CAA reserves to EPA complete discretion to decide whether to invoke the exception in (ii).[44]

If EPA takes final action on this proposed rulemaking, the Administrator intends to exercise the complete discretion afforded to him under the CAA to make and publish a finding that the final action (to the extent a court finds the action to be locally or regionally applicable) is based on a determination of ''nationwide scope or effect'' within the meaning of CAA section 307(b)(1). Through this rulemaking action (in conjunction with a series of related actions on other SIP submissions for the same CAA obligations), EPA interprets and applies section 110(a)(2)(D)(i)(I) of the CAA for the 2015 ozone NAAQS based on a common core of nationwide policy judgments and technical analysis concerning the interstate transport of pollutants throughout the continental U.S. In particular, EPA is applying here (and in other proposed and finalized actions related to the same obligations) the same, nationally consistent 4-step framework for assessing good neighbor obligations for the 2015 ozone NAAQS. EPA relies on a single set of updated, 2016-base year photochemical grid modeling results of the year 2023 as the primary basis for its assessment of air quality conditions and contributions at steps 1 and 2 of that framework. Further, EPA proposes to determine and apply a set of nationally consistent policy judgments to apply the 4-step framework. EPA has selected nationally uniform analytic years for this analysis and is applying a nationally uniform approach to nonattainment and maintenance receptors and a nationally uniform approach to contribution threshold analysis.[45] For these reasons, the Administrator intends, if this proposed action is finalized, to exercise the complete discretion afforded to him under the CAA to make and publish a finding that this action is based on a determination of nationwide scope or

[44] In deciding whether to invoke the exception by making and publishing a finding that an action is based on a determination of nationwide scope or effect, the Administrator takes into account a number of policy considerations, including his judgment balancing the benefit of obtaining the D.C. Circuit's authoritative centralized review versus allowing development of the issue in other contexts and the best use of agency resources.

[45] A finding of nationwide scope or effect is also appropriate for actions that cover states in multiple judicial circuits. In the report on the 1977 Amendments that revised section 307(b)(1) of the CAA, Congress noted that the Administrator's determination that the ''nationwide scope or effect'' exception applies would be appropriate for any action that has a scope or effect beyond a single judicial circuit. *See* H.R. Rep. No. 95–294 at 323, 324, reprinted in 1977 U.S.C.C.A.N. 1402–03.

effect for purposes of CAA section 307(b)(1).[46]

List of Subjects in 40 CFR Part 52

Environmental protection, Air pollution control, Incorporation by reference, Ozone.

Authority: 42 U.S.C. 7401 *et seq.*

Dated: July 27, 2023.

K.C. Becker,

Regional Administrator, Region 8.

[FR Doc. 2023–16441 Filed 8–11–23; 8:45 am]

BILLING CODE 6560–50–P

[46] If EPA takes a consolidated, single final action on this and any other proposed SIP actions with respect to obligations under CAA section 110(a)(2)(D)(i)(I) for the 2015 ozone NAAQS, that action may be nationally applicable, and EPA would also anticipate that in that instance, in the alternative, the Administrator would make and publish a finding that such final action is based on a determination of nationwide scope or effect.

In re: Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality Standards, 88 Fed. Reg. 36,654 (June 5, 2023)	EPA Docket Nos. EPA–HQ–OAR–2021–0668 FRL–8670–02–OAR

PETITION FOR RECONSIDERATION AND FOR STAY OF THE FEDERAL "GOOD NEIGHBOR PLAN" FOR THE 2015 OZONE NATIONAL AMBIENT AIR QUALITY STANDARDS

SUBMITTED BY

UNITED STATES STEEL CORPORATION

Pursuant to § 307 of the Clean Air Act (42 U.S.C. § 7607) and § 705 of the Administrative Procedure Act ("APA") (5 U.S.C. § 705), United States Steel Corporation ("U. S. Steel") submits this Petition for Reconsideration and Stay ("Petition") requesting that the United States Environmental Protection Agency ("EPA") reconsider and revise its Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality Standards, 88 Fed. Reg. 36,654 (June 5, 2023) ("Good Neighbor Plan" or "Final Rule").

Under the Clean Air Act, reconsideration is required to address both circumstances that arise after the close of the public comment period but before the time for judicial review, and to allow for notice and comment on elements of the final rulemaking that were not a logical outgrowth of the proposed rule. Both of these elements apply to the Good Neighbor Plan.

The factual circumstances on which the Good Neighbor Plan relied have changed dramatically since the close of the public comment period. Most significantly, courts have stayed EPA's disapproval of SIPs for ten States, denying EPA of the legal authority to promulgate the FIP for almost half of the States EPA assumed would be subject to the rule when it was proposed.

The Final Rule also contains several departures from the Proposed Rule[1] that cannot be considered logical outgrowths of the rulemaking process. These include EPA's reliance on new modelling that was not available to the public until, in some cases, the day the Administrator signed the Final Rule. For iron and steel mills, it also includes a complete rewrite of the regulatory requirements, including the introduction of a new test-and-set process for reheat furnaces that is legally impermissible and unreasonable. For boilers, the Final Rule's applicability to boilers at iron and steel mills significantly departed from the proposed rule (from 100 tons per year potential to emit to 100 MMBTU design capacity—regardless of the unit's potential to emit (with a low use exception). By EPA's own admission, the Final Rule is

[1] Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Primary Ozone National Ambient Air Quality Standard, 87 Fed. Reg. 20,036 (April 6, 2022) ("Proposed Rule").

capturing additional boilers that would not have been subject to the Proposed Rule. Final Rule at 36,819. The regulated community had no opportunity to evaluate the rule's impacts on these newly affected boilers until after the Final Rule was signed. The Final Rule also imposes requirements based on assumptions about timing that are unreasonable and subject only to an extension request process worded in such a way that it will be difficult to apply in many of the cases in which it will be needed.

Overall, the Final Rule shows repeated signs of haste making waste. Even without the stay of so many SIP disapprovals, EPA had two years from the date of SIP disapproval to develop a thoughtful and comprehensive FIP, yet EPA, without giving States an opportunity to cure any alleged SIP defects, took only two months before it signed the Good Neighbor Plan. This was not sufficient, as shown by repeated gaps and ambiguities in the regulatory language. The rule makes almost no mention, for example of how new units and units subject to the Final Rule after August 4, 2023 are to be incorporated. It inconsistently addresses co-fired emission units, exempting boilers, but not reheat furnaces, combusting the same types of fuel, and emission unit averaging, allowing it for engines in pipeline transportation but not reheat furnaces or boilers at iron and steel mills. The record is devoid of any rationale or explanation on these significant differences. Furthermore, it omits regulatory language on key elements such as deadlines for compliance for new units and units that exceed co-firing thresholds, and emission limits for emission units that burn process gases like blast furnace gas and coke oven gas. An administrative stay is necessary until EPA either corrects the numerous errors and gaps that are currently in the hastily drafted rule or rewrites the rule.

Because circumstances have materially changed since the close of the comment period and the Final Rule includes numerous substantive changes that were not subject to public notice and comment, reconsideration of the Good Neighbor Plan is required. Given the lack of record support for the Final Rule, and the serious legal questions raised by EPA's regulation of the iron and steel industry in particular, EPA should on reconsideration withdraw the Final Rule entirely, or at a minimum as to reheat furnaces and boilers at iron and steel mills.

U. S. Steel also requests that EPA stay the Good Neighbor Plan pending reconsideration and pending judicial review. The Good Neighbor Plan has been a highly contentious rulemaking that EPA is now without statutory authority to promulgate in ten States to which it nominally applies. Even in States for which EPA can still legally impose the Good Neighbor Plan, the legal and practical infirmness of the Good Neighbor Plan strongly supports either its total withdrawal or at least significant modification. But under the current deadlines, regulatory parties such as U. S. Steel have already needed to incur compliance costs and will need to continue to incur substantial costs in order to prepare to comply with regulations that likely will never be imposed in their current form. This waste of resources is unnecessary and serves no environmental benefit. A stay is therefore well-supported to allow EPA time to fully evaluate this petition for reconsideration and for judicial review of EPA's Good Neighbor Plan and associated SIP disapprovals to run their course.

Background

The Clean Air Act sets out a "basic division of labor" between EPA and the states in implementing national ambient air quality standards ("NAAQS"). *North Dakota v. EPA*, 730

F.3d 750, 757 (8th Cir. 2013). While EPA is responsible for setting and revising the NAAQS, "States have primary responsibility for attaining those standards within their borders." *Id.* (quotations omitted). In particular, when EPA revises a NAAQS, the Clean Air Act instructs each States to prepare a state implementation plan ("SIP") containing its plan for meeting the revised standard. 42 U.S.C. § 7410(a)(1). If a State submits a complete plan that meets the requirements of the Clean Air Act, EPA must approve it. *Id.* at § 7410(k)(3) ("the Administrator *shall* approve such submittal as a whole if it meets all of the applicable requirements of this chapter") (emphasis added). Only if a States fails to submit a complete SIP or submits a SIP that does not meet the requirements of the Clean Air Act, is EPA authorized to promulgate a federal implementation plan ("FIP") instead. *Id.* at §7410(c)(1). EPA has two years after finding a SIP submission incomplete or inadequate to promulgate the FIP. *Id.* During that time, the State can correct the deficiency. *Id.*

On October 1, 2015, EPA promulgated a revised primary and secondary 8-hour ozone NAAQS of 70 parts per billion ("ppb"). States were thus obligated to submit SIP revisions to EPA by October 1, 2018 that satisfied the requirements of the Clean Air Act. *See* 42 U.S.C. §7410(a)(1). These requirements included the "Good Neighbor" requirement, that State plans:

> (D) Contain adequate provisions—
>
> > (i) prohibiting, consistent with the provisions of this subchapter, any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will—
> >
> > > (I) contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any such national primary or secondary ambient air quality standard….

42 U.S.C. §7410(a)(2)(D).

Many states submitted SIPs in 2018 that satisfied this requirement. EPA was required to review these SIPs and approve them within a time period fixed by the Clean Air Act. *See* 42 U.S.C. § 7410(k)(2). Instead, EPA missed its deadline by several years and then, in 2022, proposed to disapprove the SIPs for 19 states based on modeling that EPA had performed in the meantime (the "2016v2" modeling).[2]

Merely proposing a SIP disapproval does not give EPA authority to promulgate a FIP. *See* 42 U.S.C. § 7410(c)(1). Despite this, EPA proceeded to propose its FIP for the Good Neighbor requirement for these 19 states plus several others less than two months after publishing the proposed SIP disapprovals. Proposed Rule at 20,036. EPA used the same 2016v2 modeling as the basis for its Proposed Rule. *Id.* at 20,082. Relying on this modeling, EPA proposed to include not just electric generating units ("EGUs"), as EPA had done in prior Good

[2] *See, e.g.*, Air Plan Disapproval; Illinois, Indiana, Michigan, Minnesota, Ohio, Wisconsin; Air Plan Disapproval; Region 5 Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 87 Fed. Reg. 9,838, 9,868 (February 22, 2022).

Neighbor FIPs, but several non-EGU source categories, including iron and steel mills. *Id.* at 20,039.

The Proposed Rule did not contain an adequate technical assessment of the iron and steel industry. As a result, it proposed requirements that were not technically feasible and inappropriate to meet the Good Neighbor requirement of the Clean Air Act. Notably, for reheat furnaces, EPA proposed an emission limit of 0.05 lb/mmBtu based on the unsupported assumption that NOx could be reduced 40% from recent Reasonably Available Control Technology ("RACT") limits through implementation of selective catalytic reduction ("SCR"). *See id.* at 20,145, Table VII.C–3. For boilers at iron and steel mills, EPA proposed an emission limit of 0.20 lb/mmBtu when burning coal, blast furnace gas, or coke oven gas, again without record support. *Id*. at 20,182, Table 1 to Paragraph (c). U. S. Steel and many others submitted detailed comments in response to the Proposed Rule, many of which were not addressed in the Final Rule or EPA's response to comments. U. S. Steel references and incorporates its prior comments. U. S. Steel Comments, EPA-HQ-OAR-2021-0668-0244 and -0798.

EPA published its final SIP disapprovals for 19 States on February 13, 2023,[3] and the Administrator signed the Final Rule only one month later, though it took several more months for the rule to be published in the Federal Register.

The Final Rule contained improvements over the Proposed Rule. U. S. Steel appreciates that significant effort was put into these revisions. But the Final Rule also materially departed from the Proposed Rule in key respects. First, EPA no longer relied on its 2016v2 modeling. Instead, it had developed a different "2016v3" modeling platform and chose to rely on this modeling instead. *See* Final Rule at 36,678. Much of the 2016v3 modeling was not made publicly available until EPA published the final SIP Disapproval in early 2023. Even then, EPA did not make its full modeling results available, choosing instead to withhold the results for model year 2026. *See* SIP Disapproval at 9,344, n. 49 (stating EPA was not providing 2026 results). Second, the emission limitations for reheat furnaces were completely rewritten. Rather than impose a specific NOx limit as proposed, the Final Rule imposes a "'test-and-set' requirement for reheat furnaces that will require the installation of low-NOx burners or equivalent technology" with a work plan requirement to design to a 40% reduction from a baseline to be established by future testing. Final Rule at 36,818. Reheat furnaces that do not obtain an approved work plan are prohibited from operating. *Id.* at 36,880; 40 CFR 52.43(d)(4)(v). Third, for boilers at iron and steel mills, recognizing the material differences in fuels combusted, the Final Rule appropriately imposes no numeric emission limit for combustion of blast furnace gas or coke oven gas. It does, however, limit the applicability of the FIP to a boiler that "receives 90% or more of its heat input from coal, residual oil, distillate oil, natural gas, or combinations of these fuels in the previous ozone season" and provides a method for establishing emission limitations only when combusting these fuels. *Id.* at 36,884; 40 CFR 52.45(c).

Several parties petitioned for judicial review of EPA's SIP Disapproval and moved for a judicial stay of EPA's disapprovals of certain SIPs. Those courts that have ruled on the merits of

[3] Air Plan Disapprovals: Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 Fed. Re. 9,336 (Feb. 13, 2023) ("SIP Disapproval").

these motions have uniformly granted a stay. As a result, the Courts of Appeals have now stayed the FIP as to ten States.[4] These stays prevent the FIP from taking effect in over one third of the States originally subject to the Good Neighbor Plan. Additional motions to stay are still pending and may result in the Good Neighbor Plan not taking effect in additional States. EPA has issued an Interim Final Rule already staying the Good Neighbor Plan as to several States.[5] The Interim Final Rule does not address every State in which the Final Rule cannot be applied, however. It also addresses only the effective date of the Final Rule; it does not address how EPA will confront the numerous other deadlines and requirements in the Good Neighbor Plan that will not be reconcilable with a delayed effective date for the Final Rule.

Standard for Reconsideration

Under the Clean Air Act, reconsideration is *required* "[i]f the person raising an objection can demonstrate to the Administrator that it was impracticable to raise such objection [during the period for public comment] or if the grounds for such objection arose after the period for public comment (but within the time specified for judicial review) and if such objection is of central relevance to the outcome of the rule." 42 U.S.C. § 7607(d)(7)(b). Courts have found that an objection was "impractical to raise" "when the final rule was not a logical outgrowth of the proposed rule." *Alon Refining Krotz Springs, Inc. v. EPA*, 936 F.3d 628, 648 (D.C. Cir. 2019) (*per curiam*). In other words, when interested parties would not have "anticipated that the change was possible, and thus reasonably should have filed their comments on the subject during the notice-and-comment period." *CSX Transp., Inc. v. Surface Transp. Bd.*, 584 F.3d 1076, 1080 (D.C. Cir. 2009) (internal quotations omitted). An objection is of central relevance to the outcome of the rule if it "provides substantial support for the argument that the regulation should be revised." *Chesapeake Climate Action Network v. EPA*, 952 F.3d 310, 322 (D.C. Cir. 2020).

Further, under the APA, EPA has "broad discretion to reconsider" its regulatory actions "at any time." *Clean Air Council v. Pruitt*, 862 F.3d 1, 8-9 (D.C. Cir. 2017); *see also Trujillo v. Gen. Elec. Co.*, 621 F.2d 1084, 1086 (10th Cir. 1980) ("Administrative agencies have an inherent authority to reconsider their own decisions, since the power to decide in the first instance carries with it the power to reconsider."); *United Gas Improvement Co. v. Callery Properties, Inc.*, 382

EPA*, Case No. 23-1320, ECF 5280996 (May 25, 2023) (staying Arkansas SIP disapproval); Order, *Missouri v. EPA*, Case No. 23-1719, ECF 5281126 (May 26, 2023) (staying Missouri SIP disapproval); Unpublished Order, *Texas v. EPA*, Case No. 23-60069, ECF 359-2 (June 8, 2023) (staying Mississippi SIP disapproval); *Nevada Cement Co. v. EPA*, Case No. 23-682, ECF 27.1 (July 3, 2023) (staying Nevada SIP disapproval); Order, *ALLETE, Inc. v. EPA*, Case No. 23-1776 (8th Cir. July 5, 2023); Order, *Kentucky v. EPA*, Case No. 23-3216, ECF 39-2 (July 25, 2023) (staying Kentucky SIP disapproval); Order, *Utah v. EPA*, Case No. 23-9509, ECF 010110895101 (July 27, 2023) (staying Oklahoma and Utah SIP disapprovals).

[5] Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality Standards; Response to Judicial Stays of SIP Disapproval Action for Certain States, 88 Fed. Reg. 49,295 (July 31, 2023) ("Interim Final Rule").

U.S. 223, 229 (1965) ("An agency, like a court, can undo what is wrongfully done by virtue of its order.").

Moreover, under both the Clean Air Act and APA, EPA has an obligation to "examine the relevant data and articulate a satisfactory explanation for its action including a 'rational connection between the facts found and the choice made.'" *Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 43 (1983) (quotation omitted); *see also* Unpublished Order, *Texas v. EPA*, Case No. 23-60069, ECF 269-1, at 18 (May 1, 2023) (EPA must ensure it acts within a zone of reasonableness and, in particular, has reasonably considered the relevant issues and reasonably explained its decision" and a court must "set aside any action premised on reasoning that fails to account for relevant factors or evinces a clear error of judgment.") (quotations omitted). Action that is not reasonably grounded in the record or that is taken without consideration of important aspects of the problem is arbitrary and capricious. *Id.*; 42 U.S.C. § 7607(d); 5 U.S.C. § 706.

<u>Grounds for Reconsideration</u>

Given the significant changes that have occurred since the end of the public comment period for the FIP and the numerous substantial changes from the Proposed Rule, there are several independent grounds why reconsideration is required in this case.

I. Changed Circumstances Undermine EPA's Factual Foundation for the Final Rule.

When EPA published the Final Rule, it addressed 23 States, including non-EGU industrial sources in 20 States. Final Rule at 36,654. EPA repeatedly emphasized the importance of this broad geographic reach and the need for uniform application of the Good Neighbor Plan to apply across all listed States. *See, e.g.*, Final Rule at 36,673 ("Effective policy solutions to the problem of interstate ozone transport dating back to the NOx SIP Call (63 FR 57356 (October 27, 1998)) have necessitated the application of a uniform framework of policy judgments…."); *id.* at 36,691 ("In the context of addressing regional- scale ozone transport in this rule, the importance of a uniform level of stringency that extends to and includes the [Clean Air Act] section 301(d) FIP areas geographically located within the boundaries of the linked upwind states carries significant force."); *id.* at 36,746 ("*id.* at 36,828 ("the logic of our 4-step interstate transport framework…is designed to bring all covered sources within the region of linked upwind states up to a uniform level of NOx emissions performance during the ozone season"); *id.* at 36,713 ("Considering the core statutory objective of ensuring elimination of all significant contribution to nonattainment or interference of the NAAQS in downwind states and the broad, regional nature of the collective contribution problem with respect to ozone, EPA could not identify a compelling policy imperative to move to a 1 ppb threshold."); *id.* at 36,716 ("the purpose of the Step 2 threshold within the EPA's interstate transport framework for ozone is to broadly sweep in all states contributing to identified receptors above a de minimis level in recognition of the collective-contribution problem associated with regional-scale ozone transport.").

As EPA emphasized:

> the purpose of this rule is to address the interstate transport of ozone on a national scale, and the technical record establishes that the nonattainment and maintenance receptors located throughout the country are impacted by sources of ozone pollution on a broad geographic scale. The upwind regions associated with each receptor typically span at least two, and often far more, states. Within the broad upwind region covered by this rule, the EPA is applying—consistent with the methodology of allocating upwind responsibility in prior transport rules going back to the NO SIP Call—a uniform level of control stringency (as determined separately for linkages existing in 2023, and linkages persisting in 2026). (See section V of this document for a discussion of EPA's determination of control stringency for this rule.) Within this approach, consistency in rule requirements across all jurisdictions is vital in ensuring the remedy for ozone transport is, in the words of the Supreme Court, ''efficient and equitable,'' 572 U.S. 489, 519. In particular, as the Supreme Court found in *EME Homer City Generation*, allocating responsibility through uniform levels of control across the entire upwind geography is ''equitable'' because, by imposing uniform cost thresholds on regulated States, the EPA's rule subjects to stricter regulation those States that have done relatively less in the past to control their pollution. Upwind States that have not yet implemented pollution controls of the same stringency as their neighbors will be stopped from free riding on their neighbors' efforts to reduce pollution. They will have to reduce their emissions by installing devices of the kind in which neighboring States have already invested. *Id.*

Id. at 36,691.

All of these points were made under the assumption that the Final Rule would address EGU emissions from 23 States and non-EGU emissions from 20 States. As of the filing of this Petition, however, SIP disapprovals for ten of those States have been stayed, including: Arkansas, Kentucky, Louisiana, Minnesota, Mississippi, Missouri, Nevada, Oklahoma, Texas, and Utah. Additional motions to stay are pending.[6] These SIP disapprovals are a legal prerequisite for EPA to promulgate the Good Neighbor Plan for those States. 42 U.S.C. § 7410(c)(1). Moreover, because a stay is predicated on the Courts of Appeals finding a likelihood that the petitions in those cases will succeed on the merits, there is a substantial likelihood that the FIP will never apply to most or all of these States. *See Nken*, 556 U.S. at 434. As a result, it is possible that over half the States that EPA asserted are necessary to ensure uniform efforts to reduce interstate transport of ozone, avoid generation and production shifting to less regulated states, and to ensure electric generation reliability, will not be in the Final Rule. Because their presence in the Good Neighbor Plan was a central premise of EPA's promulgation of the Final Rule, this changed circumstance alone requires reconsideration and justifies an administrative stay and a complete withdrawal or rewrite of the Final Rule.[7] Sources in the minority of States

[6] *See Ohio v. EPA*, Case No. 23-1183 (D.C. Cir); *West Virginia v. EPA*, Case No. 23-1418 (4th Cir.); *Alabama v. EPA*, Case No. 23-11196 (11th Cir.).

[7] EPA has already taken action already to stay the FIP for several of these States. Interim Final Rule at 49,295. This is not sufficient, however. Not only does it address only some of the States to which the Final Rule cannot apply, a stay of the effective date of the Good Neighbor Plan does not address EPA's lack of statutory authority to promulgate the Plan in the first place. The Clean

remaining in the FIP will be irreparably harmed and suffer significant, inequitable costs with no appreciable benefit to the air quality in downwind States. The foundation of the FIP is fatally flawed and does not serve the purpose for which it was intended.

The SIP Disapproval stays also undermine EPA's factual support for the Good Neighbor Plan. The States for which the Good Neighbor Plan is currently stayed represent a large portion of the operations that EPA assumed would be subject to its FIP as it determined what industries to regulate, what costs to consider "significant," and what emission reductions to impose. Final Rule at 36,676 ("EPA here, as it has in prior transport rulemakings for regional pollutants like ozone, identifies a uniform level of emissions reduction that the covered sources in the linked upwind states can achieve that cost-effectively delivers improvement in air quality at downwind receptors on a regional scale."); *id.* at 36,677 ("We find it reasonable in this action to again determine the amount of ''significant contribution'' at Step 3 by reference to uniform levels of cost-effective emissions controls that can be applied across the upwind sources."); *id.* at 36,683 (EPA's analysis of non-EGU emission reduction requirements "relies on evaluation of uniform levels of control stringency across all upwind states to find a level of emissions control that is cost- effective and collectively delivers meaningful downwind air quality improvement"); *id*. at 36,685 ("In this rulemaking's Step 3 analysis, the EPA is measuring emissions reduction potential from improving effective emissions rates across groups of EGUs adopting applicable pollution control measures and selecting a uniform control level whose effective emissions rates deliver an acceptable outcome under the multifactor test (including a finding of no overcontrol at the selected control stringency level)."); *id.* at 36,746 ("The EPA's criteria [for screening non-EGU industries] were intended to identify industries and emissions unit types that on a broad scale impact multiple receptors to varying degrees."). In addition, for EGUs, the number of States in the FIP has a direct correlation to the size of the trading program EPA relies on in the FIP, both to maintain a reasonable regulatory cost and to ensure adequate grid reliability. *See id.* at 36,766, n.295 (the "trading program…depend[s] on the existence of a marketplace for purchasing and selling allowances"); *id.* at 36,789 (noting the importance of "allowance market liquidity" especially during the 2024-2029 period); *id.* at 36,774 (citing "the use of a trading program as the mechanism for achieving…emissions reductions" as a factor in finding no "material risk of adverse impact to electric system reliability" and as the reason why additional accommodation for "reliability-related need" was unnecessary). EPA's policy case modeling also depended on emission reductions from these States. *See generally*, Technical Support Document (TSD) for the Final Federal Good Neighbor Plan for the 2015 Ozone National Ambient Air Quality Standards, at 3 (March 2023). As a result, EPA can no longer rely on factual record and modeling EPA used to develop the Good Neighbor Plan.

The legal and factual basis for the Good Neighbor Plan has so fundamentally changed that the Final Rule can no longer stand on the current administrative record. Because these grounds arose after the public comment period but before the time for judicial review, EPA must

---

Air Act speaks plainly to EPA's authority to promulgate a FIP, and it does not authorize EPA to promulgate a FIP at any time before disapproval of a State's SIP submission. 42 U.S.C. § 7410(c)(1). Even if the stay is only temporary, the deadlines in the FIP will not make sense or be reconcilable with the FIP taking effect after August 4, 2023. As a result, the FIP will have to be materially altered through further rulemaking in any event. So, there is no reason for EPA to hold on to what is ultimately an *ultra vires* act.

stay the effectiveness of the FIP and reconsider the FIP. The FIP reconsideration is necessary to determine whether, in light of the stay of EPA's SIP Disapproval for many States, and likely vacatur of EPA's SIP Disapproval, the FIP cannot still be equitably applied to the remaining States. Indeed, given the significant shift in the fundamental facts on which EPA attempted to equitably allocate regulatory burdens since the publication of the FIP, it is likely that reconsideration of the FIP will demonstrate that it must be withdrawn and redone entirely based on new modeling that incorporates the SIPs EPA will likely be unable to disapprove after the pending cases are complete.

II. The Final Rule was Not Promulgated in Accordance with Law and Arbitrarily and Capriciously Relied on Information Added After Public Comment.

EPA was required to include with its Proposed Rule a "statement of basis and purpose" including a summary of:

> (A) the factual data on which the proposed rule is based;
>
> (B) the methodology used in obtaining the data and in analyzing the data; and
>
> (C) the major legal interpretations and policy considerations underlying the proposed rule.

42 U.S.C. § 7607(d)(3). This information is necessary to allow for the "reasonable period for public participation" required by the Clean Air Act. *Id.* at § 760(h). When EPA relies on information that is not made part of the public record in time for meaningful public comment, EPA violates both the spirit and the terms of the Clean Air Act. *Sierra Club v. Costle*, 657 F.2d 298, 400 (D.C. Cir. 1981) (if "documents of central importance upon which EPA intended to rely ha[ve] been entered on the docket too late for any meaningful public comment prior to promulgation, then both the structure and spirit of section 307 [are] violated").

Several aspects of the Final Rule rely on information that EPA did not include in the public record in time for meaningful public comment. Those specific to iron and steel mills are addressed separately below. The most generally applicable addition, however, is EPA's 2016v3 modeling, which was used to support EPA's Step 1 and Step 2 analysis for all affected States. The Proposed Rule was based on modelling that EPA refers to as its "2016v2" modeling. *See* Final Rule at 36,673. But EPA did not rely on the 2016v2 results for the Final Rule. Instead, EPA "revised its 2016v2 modeling platform and input since the platform was made available for comment" to create the 2016v3 modeling. *Id*. at 36,674. It then "reassessed" its modeling results "to inform the final action." *Id*. These were not minor amendments. EPA "evaluated a raft of technical information and critiques of its 2016v2 modeling" and "incorporated updates into the version of the modeling used to support this final rule (2016v3)." *Id*. Further, while EPA released some of its 2016v3 results with the SIP Disapproval in February 2023, it withheld the results for model year 2026, asserting that these results were "not applicable and were not used in this final action." SIP Disapproval at 9,344, n.30. As a result, EPA did not release the full modeling results on which the Final Rule is based until the Administrator signed it in March 2023.

This delay in releasing the modeling that was central to EPA's Final Rule was "highly improper." *Small Ref. Lead Phase-Down Task Force v. EPA*, 705 F.2d 508, 540 (D.C. Cir. 1983); *Kennecott Corp. v. EPA*, 684 F.2d 1007, 1019 (D.C. Cir. 1982) ("the safety valves in the use of such sophisticated methodology [as computer modeling] are the requirement of public exposure of the assumptions and data incorporated into the analysis and the acceptance and consideration of public comment.") (alterations and quotations in original omitted). EPA's rulemaking process requires adequate public notice and an opportunity to comment. *Small Ref.*, 705 F.2d at 547. This includes providing the public with the evidence on which EPA intends to rely. *Id*. at 540.

This was also not the first time EPA switched the information on which it relied after a relevant deadline. The 2016v2 modeling that EPA relied on for the Proposed Rule was itself not introduced until EPA published its proposed SIP disapprovals for 19 States, despite the SIPs having been submitted to EPA years before based on modeling EPA released in 2018. *See, e.g.* 87 Fed. Reg. at 9,840. When EPA switched to reliance on the 2016v2 platform, it gave the public an unreasonably short time to comment, allowing only two months. *See id.* at 9,838. For the Proposed Rule, EPA offered only slightly more time, giving the public less than three months to request, process, verify, and analyze EPA's modeling results, despite numerous requests for more time, including from U. S. Steel. *See* USS FIP Comments at 42. As EPA knows, these models are large data files. They are not made part of the online docket and must be specially requested from EPA. The process takes several weeks to obtain the data and in this case several requests to obtain a full data set. Several more weeks are needed to load and verify it before EPA's modeling can be checked for errors and public comments prepared. Overall, this process typically takes two to three months, and can take longer. Two or even three months after announcing the availability of its 2016v3 modeling was simply insufficient time to allow for meaningful public participation as envisioned by the Clean Air Act. *See* 42 U.S.C. § 7607(h).

When EPA changed the game and switched models again for the final SIP Disapproval and FIP, EPA again gave no prior access to its results. EPA also did not make the complete modeling files immediately available. As raised in a separate petition for reconsideration and stay of EPA's disapproval of Minnesota's SIP (attached as Attachment B), EPA's initial release of 2016v3 modeling data was partial and inadequate to reconstruct the modeling that EPA used for its final determinations. Obtaining the necessary data, as well as checking its accuracy, took several more weeks. In the case of the 2016v3 modeling, U. S. Steel's contractor, Trinity, also needed to contact Ramboll Environ (the CAMx developer) directly to address problems with EPA's source apportionment modeling before it could be checked. This deprived U. S. Steel and the public generally of the opportunity to comment on EPA's modeling. *See Kennecott* 684 F.2d at 1019 (D.C. Cir. 1982) (finding EPA had not provided adequate opportunity for public comment on economic modeling placed in the docket only one week before promulgation of its final regulations); *Riverkeeper, Inc. v. EPA*, 475 F.3d 83, 112-113 (2d Cir. 2007) (finding EPA's Notice of Data Availability insufficient when it omitted information that would have afforded the public the opportunity to make facility-specific comments).

This procedural impropriety was centrally relevant to the outcome of the Final Rule. The 2016v3 modeling forms the basis for "EPA's understanding of projected air quality conditions and contributions" in the Final Rule, which in turn underlie EPA's selection of receptors and State contribution levels. Final Rule at 36,673. Even in the limited time the public has had with the modeling files, significant problems have been identified with EPA's 2016v3 modeling. *See* Petition for Reconsideration and Stay of the SIP Disapproval at 8-14. Correcting for these issues would likely result in at least Minnesota being excluded from the Final Rule.[8]

EPA's modeling for 2026 (which was not released until well after the close of public comment on the Final Rule) is equally important, since it informed both the application of additional emission reductions for EGUs and the introduction of emission requirements for non-EGU industrial sources. *See* Final Rule at 36,654. Indeed, in light of this modeling, EPA found that three States (Alabama, Minnesota, and Wisconsin) would be limited to emission reductions achievable by the 2024 ozone season. Final Rule at 36,660. Other States, including Arkansas and Illinois, had their compliance status change, from being modeled to interfere with attainment in 2023 to being modeled only to interference for maintenance in 2026 modeling. *See id.* at 36,710, Table IV.F–2. This information, had it been available during public comment, would have allowed commenters, including U. S. Steel to address the downward trends in significant contribution EPA has modeled for 2026 and which EPA has itself recognized are significant to identifying maintenance-only receptors. *See* EPA, Considerations for Identifying Maintenance Receptors (Oct. 19, 2018).

EPA's late publication of modeling which is central to its Final Rule violated the procedural requirements of the Clean Air Act and the APA; and justifies reconsideration to allow for full notice and public comment on the modeling supporting the Final Rule.

III. EPA Rushed Promulgation the Good Neighbor Plan in Violation of Cooperative Federalism.

EPA had two years from its SIP Disapproval to promulgate a FIP for most states. 42 U.S.C. § 7410(c)(1). EPA has asserted that it does not need to "postpone its action even a single day" after disapproving a SIP. FIP at 36,689 (*quoting EPA v. EME Homer City Generation, L.P.*, 572 U.S. 489, 509 (2014)). But the Supreme Court was speaking to whether the Clean Air Act required delay absent other considerations. The Supreme Court did not hold that EPA can steamroll State SIP authority simply because Congress did not include a minimum waiting period before EPA can promulgate a FIP. To the contrary, the Supreme Court has repeatedly held that agencies must interpret their statutory obligations "with a view to their place in the overall statutory scheme," and cannot act in a manner that is "'incompatible' with 'the substance of Congress' regulatory scheme.'" *UARG v. EPA*, 573 U.S. 302, 322 (2014) (*quoting FDA v. Brown & Williamson Tobacco Corp.*, 529 U.S. 120, 133 and 156 (2000)). When, for example, States do not submit SIPs at all, there may be no reason to wait a single day after EPA's finding of incompleteness to promulgate a FIP. Here, 19 states submitted SIPs, appropriately relying on EPA policy and guidance and air modeling that was supported by EPA and available at the time, in a good faith attempt to maintain their primary role as regulators of the Good Neighbor requirement for the 2015 ozone NAAQS. Rather than give these SIPs a full and fair evaluation,

[8] Since the submission of that petition, additional discrepancies in EPA's air quality modeling have been identified, as are being raised in the separate Petition for Reconsideration and Stay of the FIP being submitted by the Minnesota Good Neighbor Coalition contemporaneously with these comments and only further underscore that, correcting the flawed 2016v3 modeling will likely result in significant changes to the conclusions EPA reached in the Final Rule.

EPA issued late and incomplete modeling, changed its position on published guidance many States used to support their SIPs, gave only limited opportunity for public comment, and rushed out a SIP Disapproval, all with the apparent purpose of paving the way for a FIP that was equally rushed and equally short on public input. Under these circumstances, EPA's decision to simultaneously prepare a SIP Disapproval and FIP violated the Cooperative Federalism at the foundation of the Clean Air Act and was "incompatible with the substance of Congress' regulatory scheme." *UARG*, 573 U.S. at 320 (quotations omitted).

EPA was required to take sufficient time in developing its FIP to ensure that States' primary role in the NAAQS process could be fulfilled. The multiple stays of EPA's SIP Disapproval that have been issued attest to the fact that EPA did not do so here.

EPA should use its reconsideration authority as an opportunity to correct its rush to judgment, and in this instance in particular, considering the scope and complexity of the issues, use the Congressionally-provided two year period for promulgation of FIPs to both work with States on the development of compliant SIPs and, only if necessary, promulgate a FIP.

IV. The Deadlines in the Final Rule Are Incompatible with the Regulation of New Affected Units and Existing Affected Units that Become Subject to the FIP After the Effective Date.

The Good Neighbor Plan applies to two types of emission units: "existing affected units," units constructed on or before August 4, 2023; and "new affected units," units constructed after this date. *See* 40 CFR 52.40(b). Existing affected units are also not all subject to the FIP as of the Effective Date (August 4, 2023). For example, the FIP includes exemptions for low-use boilers and boilers that combust less than 90% natural gas, residual oil, distillate oil, and coal. Final Rule at 36,884; 40 CFR 52.45(b). As a result, even an existing affected unit can become subject to the FIP years after August 4, 2023.[9] The Final Rule, however, makes no provision for these units. With only limited exceptions, compliance dates, submission deadlines, and reporting requirements are recorded as fixed dates in the Final Rule, rather than running from the date of applicability. The result is an ambiguous set of irreconcilable deadlines for units that are not subject to the FIP as of August 4, 2023.

Overall, EPA should reconsider and revise the FIP to comprehensively address these issues, but U. S. Steel identifies several particular examples where post-Effective Date applicability creates particular problems.

A. The Final Rule Does Not Give Sufficient Time for Co-Fired Boilers and Reheat Furnaces.

While the Proposed Rule included emission limits for co-fired boilers, the Final Rule applies only to boilers that combust 90% or more natural gas, distillate oil, residual oil, or coal in the previous ozone season. Final Rule at 36,884; 40 CFR 52.45(b). As discussed in Ground for Reconsideration VIII below, the same exemption should be included for reheat furnaces as well.

---

[9] Similarly, for existing affected units in states subject to a stay of the FIP, if they will become subject to the FIP at all, it will be at a date after August 4, 2023.

In either case, therefore, there is a possibility that a co-fired unit will lose the exemption if it stops burning process gas at some point in the future for an ozone season. Yet the Final Rule offers no language directly addressing when such units must meet the requirements of the Good Neighbor Plan.

To the extent this would mean that a boiler, for example, will need to be prepared to comply with the Good Neighbor Plan by the start of the next ozone season, this would entail potentially installing CEMS, obtaining permits, designing and installing pollution control equipment, and implementing recordkeeping and reporting requirements within a matter of months, not the nearly four years allowed for boilers subject to the Final Rule as of the Effective Date. For reheat furnaces, it would entail preparing a work plan and having it approved by EPA within a similarly short time period.

The time EPA has allowed for boilers to comply with the Final Rule was meant accommodate the real-world practical requirements of designing, installing and testing new pollution control equipment. *See* NOx Control Installation Timing Report ("Timing Report"). Interim deadlines were fixed to allow each step. As discussed in Ground for Reconsideration XII below, the schedule for boilers does not sufficiently accommodate these requirements and should be extended, but it is arbitrary and capricious to subject units that were exempt from compliance to an even shorter deadline. Indeed, EPA recognized in the Proposed Rule that a "3-year period for installation of post-combustion control technologies is consistent with the statutory timeframe for implementation of the controls required to address interstate pollution under section n110(A)(2)(D) and 126 of the [Clean Air] Act, the statutory timeframes for implementation of RACT in ozone nonattainment areas classified as Moderate or above, and other statutory provisions that establish control requirements for existing stationary sources of pollution." Proposed Rule at 20,101. There is no justification in the record for why a substantially shorter time should apply to emission units that lose an applicable exemption.[10]

EPA must address the lack of deadlines for post-Effective Date boilers and reheat furnaces on reconsideration. In doing so, EPA should allow the same time to achieve compliance as current units subject to the FIP effective August 4, 2023.

B. Compliance Dates for States in which the Good Neighbor Plan has been Stayed Must be Extended.

As discussed above, the Good Neighbor Plan has been stayed, either by court order or Interim Final Rule, in ten states already, with the possibility that additional stays will be issued. In these states, the Good Neighbor Plan will not take effect August 4, 2023. Neither the Final Rule nor the Interim Final Rule, however, makes accommodation for extending the deadlines in the Good Neighbor Plan for emission units subject to a stay.

As one example, owners and operators of reheat furnaces are to submit work plans by August 4, 2024. Final Rule at 36,879; 40 CFR 52.43(d). To do this will reasonably require a

[10] Even for the low-use exemption, which EPA has asserted must result in compliance in one year, there is nothing in the record to support this short of a compliance deadline. Final Rule at 36,884; 40 CFR 52.45(b)(2)(i).

year of work, as EPA anticipated when it set the deadline one year after the Effective Date. Yet owners and operators in a State subject to a stay cannot reasonably be expected to develop work plans until the stay is lifted. This may not occur before August 4, 2024 and, if it does, it will still not leave sufficient time to develop the required content. As a result, to fulfill the requirements of the stay orders currently in place, and to preserve the *status quo* prior to promulgation of the SIP Disapproval, EPA must extend this and other deadlines in the Final Rule to allow reasonable time to comply after the stays are lifted.

C. The Final Rule's Procedures for Requests for Extension and Case-By-Case Emission Limits Do Not Address Post-Effective Date Applicability.

EPA requested comment in the Proposed Rule on "whether the FIP should provide a limited amount of time beyond the 2026 ozone season for individual non-EGU sources to meet the emissions limitations and associated compliance requirements, based on a facility-specific demonstration of necessity." Final Rule at 20,104. EPA did not propose a process for case-by-case emission limits.

In the Final Rule, EPA promulgated procedures for both requesting an extension of compliance (40 CFR 52.40(d)) and requesting a case-by-case emission limit (40 CFR 52.40(e)). Final Rule at 36,870-71. Neither of these procedures was provided in the Proposed Rule, so it would have been impracticable to raise objections to EPA's procedure during public comment. 42 U.S.C. § 7607(d)(7)(B).

While U. S. Steel supports providing flexibility to owners and operators, both in terms of the compliance schedule and the emission limits in the Final Rule, the procedures EPA has adopted leave significant issues unaddressed. The Final Rule language does not mention new affected units at all, and by including specific dates for applications and dates to which compliance can be extended, the Final Rule does not adequately address existing affected units that become subject to the Good Neighbor Plan after August 4, 2023.

The current language in 40 CFR 52.40(d), for example, allows the "owner or operator of an existing affected unit" to "request an initial compliance extension to a date certain no later than May 1, 2027," almost four years after the Effective Date of the Final Rule. Final Rule at 36,870; 40 CFR 52.40(d)(1). A second extension can be requested to "a proposed compliance date no later than May 1, 2029." *Id;* 40 CFR 52.40(d)(3)(v). These deadlines would be inequitable if applied to emission units that become subject to the Good Neighbor Plan after August 4, 2023, and, of course, do not make sense at all for an emission unit that becomes subject to the Good Neighbor Plan after each date.

EPA included the extension provision because it found "not all facilities may be capable of meeting the control requirements" by 2026, though EPA acknowledged that the "circumstances where an extension may be warranted for any specific facility are unknown at this time and will be evaluated through a source-specific application process, where the need for extension can be established with source-specific evidence." Final Rule at 36,664 and 36,749. There is no rational basis why similar source-specific showings of necessity should not justify a comparable extension for other units that become subject to the Good Neighbor Plan after the Effective Date.

Similarly, in the Final Rule, EPA recognized that "there may be unique circumstances the Agency cannot anticipate that would, for a particular source, render the final emissions control requirements technically impossible or impossible without extreme economic hardship." Final Rule at 36,818. To address this, EPA included "a provision that allows a source to request EPA approval of a case-by-case emissions limit based on a showing that an emissions unit cannot meet the applicable standard due to technical impossibility or extreme economic hardship." *Id.* Since technical impossibility and extreme economic hardship are not limited to existing affected units subject to the Final Rule as of the Effective Date, there is no reasonable basis for EPA to exclude units subject to the Good Neighbor Plan after the Effective Date from the same opportunity. Yet the language EPA chose for the Final Rule requires requests to be submitted "by August 5, 2024." Final Rule at 36,781; 40 CFR 52.40(e)(1).

EPA should reconsider its use of fixed dates in the Final Rule and instead adopt deadlines based on the date of applicability of the FIP to an affected unit.

V. EPA Has Not Justified Including Reheat Furnaces and Boilers at Iron and Steel Mills in the Final Rule.

The Final Rule does not regulate every source of NOx in each upwind State nor should it. Instead, EPA attempted to "focus[] on the most impactful industries and emissions units as determined by [the Agency's] evaluation of the power sector and the non-EGU screening assessment prepared for the proposal….." Final Rule at 36,682. This screening assessment determined which industries would be subject to the Good Neighbor Plan. Indeed, of the 41 industries EPA examined in this screening assessment, EPA selected only nine for inclusion in the Final Rule. *Id.* This screening assessment was also used "[t]o identify appropriate control strategies for non-EGU sources to achieve NOx emissions reductions that would result in meaningful air quality improvements in downwind areas" and to assess control costs. *Id.* at 36,661, 36733. Thus, the screening assessment formed a significant basis for EPA's inclusion of regulations for reheat furnaces and boilers at iron and steel mills in the Final Rule and EPA's selection of appropriate emission reductions for them.

This screening assessment did not identify all emissions from each industry. Rather it focused on "potentially controllable emissions," which it identified by focusing on sources that could provide "the most emissions reductions" at a marginal cost threshold. Screening Assessment at 2. "[W]ell-controlled sources" were expressly to be "excluded from consideration." *Id.* at 3. At the time of the Screening Assessment, EPA assumed, incorrectly, that emissions from co-fired boilers, blast furnaces, casting and tapping, basic oxygen furnaces, sintering, and other processes, all constituted "potentially controllable emissions." *See id.* at 17, Table 6. In the Final Rule, however, EPA appropriately recognizes that additional emission reductions from these sources are not technologically or economically feasible. *See* Final Rule at 36,827 ("the data we have reviewed is insufficient at this time to support a generalized conclusion that the application of NOx controls, including SCR or other NOx control technologies such as LNB, is currently both technically feasible and cost effective on a fleetwide basis for these emission source types in this industry"); *id.* at 36,833 ("The EPA does not have sufficient information at this time to conclude that [boilers] burning more than 10 percent fuels other than coal, residual or distillate oil, or natural gas can operate the necessary controls effectively and at a reasonable cost."). As a result, the Screening Assessment overcounted emissions from iron and steel mills. This required updating before EPA relied on the Screening Assessment results in the Final Rule. It was not. Instead, the Final Rule continues to rely on the same, obsolete and incorrect, Screening Assessment. *Id.* at 36,732-33.

This results in the inconsistent treatment of iron and steel mills as compared with other industries with comparable "potentially controllable emissions," and ultimately, results in a Final Rule that is inconsistent with the record and inequitable impacts.

U. S. Steel already submitted comments on the technical and economic infeasibility of the assumptions made in the Screening Assessment. *See, e.g.*, USS FIP Comments at 13-18. EPA's decision to continue to rely on the Screening Assessment in the Final Rule, however, despite the inaccuracy of its assumptions about the availability of additional emission reductions from the iron and steel mill industry did not arise until the Final Rule and so would have been impracticable to raise in public comments on the Proposed Rule. 42 U.S.C. § 7607(d)(7)(B).

On reconsideration, EPA should revise its Screening Assessment to address only emissions from iron and steel mills associated with reheat furnaces and boilers combusting natural gas, residual oil, distillate oil, and coal. In addition, as discussed in Ground for Reconsideration VI below, the iron and steel industry is subject to many additional and pending NOx reduction requirements that will further limit the availability of additional emission reductions. Since these were not factored into EPA's initial Screening Assessment, reconsideration will present the opportunity for to EPA incorporate a more up-to-date and realistic assessment of reheat furnace and boiler impacts on downwind ozone concentrations, which will likely result in the conclusion that the iron and steel industry, like many other industries, should not be subject to the Good Neighbor Plan.

VI. The Final Rule Did Not Adequately Consider the Cumulative Burdens of Pending EPA Regulations.

The Good Neighbor Plan is only one of many regulations impacting the iron and steel industry, including the same reheat furnaces and boilers subject to the Final Rule, including:

- National Emission Standards for Hazardous Air Pollutants: Taconite Iron Ore Processing Amendments, 88 Fed. Reg. 30,917 (proposed May 15, 2023);
- National Emission Standards for Hazardous Air Pollutants: Integrated Iron and Steel Manufacturing Facilities Technology Review, 88 Fed. Reg. 49,402 (proposed July 31, 2023);
- Standards of Performance for Steel Plants: Electric Arc Furnaces Constructed After 10/21/74 & On or Before 8/17/83; Standards of Performance for Steel Plants: Electric Arc Furnaces & Argon-Oxygen Decarburization Constructed After 8/17/83, 87 Fed. Reg. 29,710 (signed Aug. 1, 2023) (https://www.epa.gov/stationary-sources-air-pollution/electric-arc-furnaces-eafs-and-argon-oxygen-decarburization);

- Proposed Amendment to Air Toxics Standards for Coke Ovens Pushing, Quenching and Battery Stacks; and Coke Oven Batteries (Residual Risk and Technology Review, and Periodic Technology Review (proposed rule signed by EPA Administrator Regan on July 31, 2023. (https://www.epa.gov/stationary-sources-air-pollution/coke-ovens-batteries-national-emissions-standards-hazardous-air);

- Reconsideration of the National Ambient Air Quality Standards for Particulate Matter, 88 Fed. Reg. 5,558 (proposed Jan. 27, 2023); and

- EPA Announcement: EPA to Reconsider Previous Administration's Decision to Retain 2015 Ozone Standards, https://www.epa.gov/ground-level-ozone-pollution/epa-reconsider-previous-administrations-decision-retain-2015-ozone.

In developing the Good Neighbor Plan, EPA aimed to incorporate "emissions reductions from on-the-books actions, planned emissions control installations, and promulgated Federal measures that affect anthropogenic emissions" in its 2023 and 2026 emission inventories. Final Rule at 36,698. EPA did not, however, incorporate emission reductions from these and other rules that will significantly impact that NOx emissions from the iron and steel industry.

Equally problematic, while EPA has sought to reflect emission reductions from other regulations, EPA did not incorporate these other obligations into the Good Neighbor Plan's selection of emissions control strategies and calculation of compliance costs. The result is a rule that does not adequately consider the circumstances facing the regulated community. *See* Declaration of Alexis Piscitelli at ¶¶20-28 (attached hereto as Attachment A).

Siloed rulemakings present a jigsaw puzzle of requirements that U. S. Steel and others must piece together under strict compliance deadlines. At a minimum, this is inefficient and not conducive to maximizing environmental benefit. At worst, it can result in conflicting and inconsistent legal requirements. *See id.* As one clear example, EPA is rushing to impose the Good Neighbor Plan to address the 2015 ozone NAAQS while it has already announced its intention to reconsider those standards.[11] It does not make sense to expend millions of dollars in designing and implementing pollution controls to meet standards that EPA is in the process of reconsidering.

On reconsideration, EPA should incorporate consideration of all pending iron and steel industry regulations, which will further support exclusion of reheat furnaces and boilers from a final revised Good Neighbor Plan.

---

[11] https://www.epa.gov/ground-level-ozone-pollution/epa-reconsider-previous-administrations-decision-retain-2015-ozone.

VII. The August 4, 2023 Deadline for Federally Enforceable Changes to Potential to Emit for Reheat Furnaces is Unreasonable.

The Final rule requires limitations on a reheat furnace's potential to emit to be effective by the Effective Date of the Good Neighbor Plan to be relevant to determining applicability. Final Rule at 36,879; 40 CFR 52.43(b) ("Any existing reheat furnace with a potential to emit of 100 tons per year or more of NOx on August 4, 2023, will continue to be subject to the requirements of this section even if that unit later becomes subject to a physical or operational limitation that lowers its potential to emit below 100 tons per year of NOx."). This aspect of determining potential to emit was not part of the Proposed Rule or a logical outgrowth of the Proposed Rule. As a result, it was impracticable to comment on it during the public comment period. 42 U.S.C. § 7607(d)(7)(B).

EPA has given no reason for adding this provision in the Final Rule in its statement of basis and purpose. This alone violates the procedural requirements of the Clean Air Act. 42 U.S.C. § 7607(d)(6). It is also improper. Long-standing EPA policy approves the use of legally-enforceable limitations on potential to emit to conform emission units to the applicability requirements of EPA's Clean Air Act regulations. *See, e.g.* EPA, Options for Limiting the Potential to Emit (PTE) of a Stationary Source Under Section 112 and Title V of the Clean Air Act (Act), EC-6-1998-29 (Jan. 25, 1995). Removing this option requires a "reasoned explanation," which is absent from the Final Rule. *U.S. Sugar Corp. v. EPA*, 830 F.3d 579, 626 (D.C. Cir. 2016); *see also FCC v. Fox Television Stations, Inc.*, 556 U.S. 502, 515 (2009).

Limiting the time in which potential to emit can be changed is also of questionable value. A federally-enforceable limitation on potential to emit puts an existing affected emission unit in the same position whether the limitation is adopted before or after August 4, 2023. It also puts existing affected units in the same position as new affected units, which can design to a potential to emit after the Effective Date.

EPA has also not applied these requirements consistently across industries. Similar provisions are included in the Final Rule for iron and steel, cement, and glass manufacturing. *See* 40 CFR 52.42(b), 52.43(b), and 52.44(b). But the Final Rule does not impose similar time restrictions on emission units in other non-EGU industries. *See* 40 CFR 52.41(b), 52.45(b), and 52.46(b). The lack of any explanation why certain industries are barred from relying on federally-enforceable limitations after a specific date is a material omission from the Final Rule.

As a practical matter, it is also unfair to subject owners and operators to applicability requirements that require State involvement and quick turnaround. Obtaining federally-enforceable limitations on potential to emit typically requires amendment of State-issued permits. EPA's own Timing Report states that even minor permit modifications can take "a few weeks or months." Timing Report at ES-3. As discussed in Ground for Reconsideration XI below, this is overly optimistic in many cases, particularly when permitting offices are backlogged. FIP applicability should not depend on such factors.

EPA should reconsider the inclusion of this provision in 40 CFR 52.43(b) and remove it. Even if EPA were to conclude that some cut-off for applying physical and operational limitations on potential-to-emit is necessary (and EPA justifies such a cut-off in the statement of basis and purpose as required by the Clean Air Act), EPA should select a date that is both grounded in the emission reduction requirements of the Good Neighbor Plan and that does not unfairly prejudice facilities in States with significant permitting backlogs. For example, under the current Good Neighbor Plan, there is no justification for imposing such a requirement before May 1, 2026, the "compliance date that generally applies to all affected units in the non-EGU industries covered by this final rule." Final Rule at 36,818.[12]

VIII. EPA Should Exempt Co-Fired Reheat Furnaces from the Good Neighbor Plan.

The Final Rule acknowledges that "EPA does not have sufficient information at this time to conclude that [boilers] burning more than 10 percent fuels other than coal, residual or distillate oil, or natural gas can operate the necessary controls effectively and at a reasonable cost." Final Rule at 36,833. EPA does not appear to have considered that similar fuels are used by reheat furnaces, let alone put information in the record to support treating reheat furnaces and boilers that combust more than 10% process gas differently. Indeed, as explained in U. S. Steel's FIP Comments, low-NOx burners were also recently eliminated as a control option for blast furnace stoves fueled primarily by blast furnace gas, and they offer limited potential for emission reduction in light of co-firing and negative energy usage impacts arising from the lower flame temperature with low-NOx burners. thermodynamics of heat transfer to the steel in a reheat furnace. USS FIP Comments at 15 and Exhibit D at § 1.2.5. EPA's finding that there is "[in]sufficient information at this time to conclude that units burning more than 10 percent fuels other than coal, residual or distillate oil, or natural gas can operate the necessary controls effectively and at a reasonable cost" applies equally to reheat furnaces. Yet the Final Rule includes no similar provision excluding reheat furnaces that burn more than 10 percent process gas from the Good Neighbor Plan. U. S. Steel fully supports the exemption of boilers that combust primarily process gas from the Good Neighbor Plan. But having introduced this exemption in the Final Rule, EPA must also apply it consistently.

The applicability provisions for reheat furnaces and boilers were substantially rewritten from the Proposed Rule, and EPA did not raise in the Proposed Rule that it was considering a heat input exemption for process gas-fired emission units. As a result, it would have been impracticable to address EPA's omission of the exemption for reheat furnaces during the public comment period. 42 U.S.C. § 7607(d)(7)(B). On reconsideration, EPA should incorporate a similar exemption for reheat furnaces.[13] Even if EPA determines that reheat furnaces that co-fire process gas should be subject to the Good Neighbor Plan (and provides an adequate explanation for including them), at a minimum, EPA should clarify the determination of potential to emit for these units. As reflected in the emission requirements for boilers, the use of different fuels results in a different NOx emission rate for comparable heat input. *See* 40 CFR 52.45(c). Similarly, in determining potential to emit for co-fired reheat furnaces, a 100 tpy threshold would

[12] The Final Rule technically omits this language from the emission limitation in 40 CFR 52.43(c). This was clearly an omission and should be corrected on reconsideration as well, to make clear that the emission limit applies "[b]eginning with the 2026 ozone season" or, as discussed in Ground for Reconsideration IV above, within three years following the date the Good Neighbor Plan becomes applicable to an emission unit.

[13] As discussed in Ground for Reconsideration IV above, deadlines should also be included in 40 CFR 52.43(c) for furnaces that lose this exemption after the Effective Date.

capture differently-sized units depending on whether potential to emit is determined based on combustion of natural gas or process gas.

IX. The Work Plan Process for Reheat Furnaces is *Ultra Vires* and Violates Due Process.

A Good Neighbor implementation plan is to contain emission limitations ("prohibit[ions]" on "emissions activity"). 42 U.S.C. § 7410(a)(2)(D)(i). The Clean Air Act sets forth specific procedural requirements EPA must follow to impose these emission limitations. 42 U.S.C. § 7607(d). This includes publication of a proposed rule in the Federal Register, provision of a statement of basis and purposes, creation of a public docket of supporting material, public comment, and response to significant comments. *Id.* at § 7410(d)(3)-(6). Public participation must be for "a reasonable period" and by "at least 30 days" unless expressly provided for otherwise in the Clean Air Act. *Id*. at § 7607(h). Final emission limitations are also subject to judicial review. *Id.* at § 410(d)(7).

The Final Rule does not impose emission limitations on reheat furnaces. Instead, it imposes a "test-and-set requirement for reheat furnaces that will require the installation of low-NOx burners or equivalent technology." Final Rule at 36,818. Specifically, it requires owners and operators to submit a work plan and "establish an emissions limit in the work plan that the affected unit must comply with." *Id.* at 36,879; 40 CFR 52.43(d)(3). U. S. Steel agrees with EPA's conclusion that "[d]ue to variations in the emissions rates that different types of reheat furnaces can achieve," EPA should not "finaliz[e] one emissions limit for all reheat furnaces." Final Rule at 36,828. And while EPA recognized that furnace-specific factors make a universal one-size-fits-all approach inappropriate for reheat furnaces, it somehow disregarded these factors when imposing a universal reduction mandate in the Final Rule. A universal reduction of 40% from baseline is not appropriate because it does not take into account what is achievable for each reheat furnace, including what the baseline value actually is—whether, for example, it is 0.12 lb/MMBtu or 0.24 lb/MMBtu, what limits there are on the type of NOx reduction technology that can be used, what fuels the reheat furnace uses, what other pollution control technologies are already in place, or other factors that would make a minimum 40% reduction on some units technically or economically infeasible. *See* Attachment A at ¶¶11-12. EPA's own analysis of low-NOx burners shows this bearing true, as it merely cites to an application of low-NOx burners at a reheat furnace that achieved a 20% reduction in NOx. *See* Proposed Rule at 20,145, Table VII.C-3. EPA has not provided any basis for the 40% reduction requirement—and such a requirement is devoid of any explanation and is therefore arbitrary and capricious.

U. S. Steel appreciates that EPA was looking to provide flexibility through the work plan process in the Final Rule, both on phased construction timeframes and the final emission limits. The logical result or outgrowth of finding that there is insufficient information in the record to support an emission limit for reheat furnaces, however, is to exclude reheat furnaces from the Good Neighbor Plan—not to establish a mandate the reduce NOx by 40% from baseline. EPA cannot put in a placeholder and then use a work plan process to develop future record support. 42 U.S.C. § 7607(d)(6)(C) ("The promulgated rule may not be based (in part or whole) on any information or data which has not been placed in the docket as of the date of such promulgation."). The procedure EPA has included in the Final Rule for establishing the final emission limits for reheat furnaces falls short of these requirements. U. S. Steel and others similarly situated had no opportunity to comment on the Work Plan requirement or the 40% reduction mandate.

The work plan process in the Final Rule also raises serious Due Process concerns. The Final Rule provides that the Administrator will determine completeness of a work plan within 60 calendar days (40 CFR 52.43(d)(4)(i)), and then, within 60 calendar days after notification of a complete work plan, notify the owner and operator via CEDRI or analogous electronic submission system whether EPA approves the work plan (40 CFR 52.43(d)(4)(iv). Final Rule at 36,879-80. The Final Rule does not say what is to be done if the Administrator approves the work plan, but if the Administrator does not approve it, the owner or operator has only 15 calendar days to present in writing additional information or arguments, after which the Administrator can issue a final decision disapproving the work plan. *Id.* at 36,880; 40 CFR 52.43(d)(4)(iii). If the Administrator disapproves a work plan or finds or work plan was not timely submitted or completed, "[e]ach day that the affected unit operates following such disapproval of failure to submit shall constitute a violation." *Id.*; 40 CFR 52.43(d)(v).

This work plan process raises several concerns. First, this effectively imposes an emission limit of zero, unless an owner or operator can demonstrate to EPA's satisfaction that a higher limit should apply. This turns the rulemaking process on its head and finds no support in the Clean Air Act.

Second, the procedural rights it affords clearly fall short of what would be required for a prohibition on operation. Even in the case of a 126 petition, through which the Clean Air Act expressly authorizes EPA to limit the emissions of a particular "major source or group of major sources" to prevent "violation of the prohibition of section 7410(a)(2)(D)(ii)," the Clean Air Act requires both a public hearing and the provision of at least three months for a source to come into compliance while continuing to operate. 42 U.S.C. § 7426(b). There is no justification for imposing an even more draconian ban—with less process—through implementation of a FIP that is expressly required to avoid over-control. *See, e.g.*, Final Rule at 36,704; *EME Homer City*, 572 U.S. at 523.

Third, EPA's work plan process circumvents the notice and comment rulemaking procedure EPA is required to follow in 42 U.S.C. § 7607(d), including publication of both the proposed and final emission limit in the Federal Register, provision of at least 30 days for public comment, a requirement that EPA will respond to all significant comments, requirement that issuance of the final decision and statement of basis will be published in the Federal Register, and that EPA's final decision will be subject to judicial review. In the regional haze test-and-set process EPA adopted for certain taconite furnaces, for example, the emission limits to be set become enforceable "only after EPA's confirmation or modification of the emission limit in accordance with" procedures that include EPA taking "final agency action by publishing its final confirmation or modification of the NOx limit in the Federal Register." *See, e.g.*, 40 CFR 42.1235(b)(1)(ii)(A)(1)-(7). No such protections are afforded in the Good Neighbor Plan.

Finally, even if EPA's work plan process could be squared with the procedural requirements of the Clean Air Act, the current regulations do not provide sufficient clarity on the grounds on which the Administrator will determine whether a work plan "is complete, that is, whether the request contains sufficient information to make a determination" or fails "to satisfy the requirements of paragraphs (c) and (d)(1) through (3) of this section." Final Rule at 36,880; 40 CFR 52.43(d)(4)(i) and (v). As currently promulgated, the work plan process is so vague as to necessarily result in an arbitrary and capricious decision.

This work plan process was not proposed in the Proposed Rule and U. S. Steel had no notice that EPA was considering it prior to the Final Rule.[14] EPA must grant reconsideration to address the flaws in its work plan process for reheat furnaces and should, on reconsideration, remove reheat furnaces entirely from the Good Neighbor Plan.

X. The Work Plan Requirements for Reheat Furnaces Are Not Supported by the Record.

As noted in Ground for Reconsideration IX above, EPA did not propose a work plan process for reheat furnaces in the Proposed Rule. As a result, it would have been impracticable to comment on the target emission reductions and schedule in the Final Rule during public comment. As discussed in Ground for Reconsideration IX above, the reheat furnace requirements should be withdrawn entirely. If they are not, EPA must reconsider the requirements in these aspects of the Final Rule as well.

A. A Minimum 40% Reduction in NOx from Installation of Low-NOx Burners is Not Justified by the Record.

The Final Rule requires existing affected units to "install and operate low-NOx burners or equivalent alternative low-NOx technology designed to achieve at least a 40% reduction from baseline NOx emissions." 40 CFR 52.43(c). But EPA nowhere explains where this 40% target comes from. In the Proposed Rule, EPA proposed a 40% reduction through selective catalytic reduction ("SCR"). Proposed Rule at 20145, Table VII.C-3. Commenters, including U. S. Steel, submitted information showing that SCR is not technically feasible and its use was not supported by the record. *See, e.g.*, USS FIP Comments at 14-15. In the Final Rule, EPA has switched to reliance on low-NOx burners. Final Rule at 36,818. But EPA has not pointed to evidence that a 40% reduction is feasible for low-NOx burners. To the contrary, the Proposed Rule gives as an example a reheat furnace with low-NOx burners at Sterling Steel, which achieved less than a 20% reduction from the Ohio NOx RACT limit EPA used as its baseline for determining feasible NOx reductions. *See* Proposed Rule at 20145, Table VII.C-3.

As discussed in Ground for Reconsideration VIII above, EPA should exclude co-fired reheat furnaces from the Good Neighbor Plan entirely. If it does not, the 40% reduction goal presents an additional problem for these units. There is nothing in the record on their emission reduction potential from installation of low-NOx burners. Indeed, some process gases (like blast furnace gas) are by nature low-NOx. A 40% reduction is not demonstrated as feasible from these units. Combustion of coke oven gas introduces additional complications. NOx generation

[14] The only emission units subject to a work plan in the Proposed Rule were taconite furnaces in the metal ore mining industry. Proposed Rule at 20,182. This was based on a work plan process negotiated by EPA as a resolution to various rulemaking challenges to the 2016 Minnesota Regional Haze Federal Implementation Plan. A proposal to apply a specific work plan process to one industry is not notice that EPA is considering applying a different work plan process to different emission units in a different industry.

can vary significantly based on the nitrogen content of the process gas. This variability would have to be factored into determining an emission reduction potential for reheat furnaces that burn coke oven gas.

More generally, it is inconsistent with the work plan process for EPA to impose a minimum emission reduction requirement across all units. If the purpose of the work plan is to evaluate what is feasible for each unit, *see* 40 CFR 52.43(d)(3), the engineering evaluation of what is feasible should guide the emission reductions. As a result, if a work plan process is included following reconsideration, EPA should require installation of "cost effective emission controls" in accordance with the work plan, not a predetermined target reduction. *See, e.g.* Final Rule at 36,746.

B. The Schedule for Reheat Furnaces is Not Feasible.

The Final Rule requires owners and operators to submit a work plan by August 5, 2024. Final Rule at 36,879; 40 CFR 52.43(d)(1). The work plan approval process involves two rounds of EPA review, for completeness and approval, which will result in a final work plan by late 2024 or early 2025. *Id.*; 40 CFR 52.43(d)(4). Certification of installation is then due March 30, 2026. *Id.*; 40 CFR 52.43(g). This leaves approximately 15-16 months from work plan approval to completion of installation.

In U. S. Steel's experience, this is greatly insufficient. U. S. Steel has prepared a schedule for installation of low-NOx burners on the four reheat furnaces at U. S. Steel – Gary Works' 84" Hot Strip Mill. *See* Attachment A at Attachment 1, Appendix A. Even without the delay inherent in waiting for work plan approval, installation of low-NOx controls is expected to take until May 2027. Comparing this to EPA's assessment of the timing for compliance in the Timing Report, which was released with the Final Rule, it is clear that EPA underestimates the time required for initial evaluation and work plan approval, the likely time needed for permitting, and the time needed for fabrication and construction of pollution control requirement.

1. EPA's Timing Report Does Not Consider Work Plan Approval

The Timing Report assumes that implementation can begin in Month 3 (November 2023 for the Final Rule). Timing Report at 22. As noted above, however, EPA will not approve work plans until December 2023 or January 2024, assuming no delay on EPA's part in reviewing and approving work plans. Approval could take significantly longer if EPA is delayed or there is a need for supplemental information. Nowhere in the Timing Report does EPA appear to have considered the impact of this delay. Work plans are not mentioned at all and there is no time provided for their approval. Given EPA's assumption that all work can be completed in 15 months, the loss of even two months is significant and undermines EPA's compliance deadlines for reheat furnaces.

2. The Timing Report Underestimates Vendor Availability.

The Timing Report recognizes that vendor demand and capacity can introduce delays. Timing Report at 41. The Report appears to conclude that vendor capacity will not be a cause of delay, but U. S. Steel is already experiencing problems obtaining vendor quotes and finding and scheduling qualified union contractors. *See* Attachment A at ¶¶9 and 10. These issues are likely to get worse as EPA continues to implement additional Clean Air Act regulations that impose additional obligations on the iron and steel industry. *See id.* at ¶¶26-27. In addition, EPA's Timing Report only evaluates vendor availability for SCR and SNCR installation. Timing Report at 41-42. It does not assess the availability of low-NOx burner vendors for work on reheat furnaces, which is the technology EPA selected in the Final Rule. Here too U. S. Steel has found difficulty obtaining sufficient vendor quotes to proceed. Attachment A at ¶9.

3. The Final Rule Underestimates Permitting Times.

The Timing Report assumes that permitting can be completed in six months, despite noting that permitting can take over a year and may take longer. Compare Timing Report at 22 with ES-3. The Report does not reconcile these discrepancies. It appears to simply conclude that state permitting offices should be able to move quickly as long as they are not backlogged with other work. But EPA does not evaluate what other work States will be doing in the same timeframe. In Indiana, for example, EPA estimates that the Good Neighbor Plan will result in an additional 51 permit applications for non-EGU control installations alone. Timing Report at 44, Table 4-15. EPA assumes this will take 2,200 hours of work, which EPA assumes Indiana can compress into six months without any consideration of other permitting requirements that may arise in the same timeframe.

Combined, these delays make the schedule in the FIP highly unlikely. On reconsideration, if EPA retains a work plan process, EPA should revise the compliance schedules to allow sufficient time for work plan approval, engineering, permitting, installation, and testing prior to the certification date. At a minimum, this should allow for implementation through the 2027 ozone season.

XI. The Applicability Determination for Boilers at Iron and Steel Milles was Not a Logical Outgrowth of the Proposed Rule.

The Proposed Rule proposed to regulate boilers at iron and steel mills that "directly emits or has the potential to emit 100 tons per year or more of NOx." Proposed Rule at 20,181. EPA gave no notice that it was considering other applicability thresholds for boilers at iron and steel mills. In the Final Rule, however, EPA switched the applicability requirement to "a design capacity of 100 mmBtu/hr" and other restrictions. Final Rule at 36,884; 40 CFR 52.43(b). This was a significant departure, which EPA acknowledges captured more boilers than originally proposed. *See id.* at 36,819. EPA afforded the regulated community no opportunity to review the effects and applicability on these additional boilers until the Final Rule was released, however. This alone was improper. *Small Ref.*, 705 F.2d at 547 ("the final rule must be a logical outgrowth of the proposed rule") (quotations omitted). Furthermore, EPA has not adequately supported its contention that a boiler with a PTE of 100 tons is comparable to a boiler with a design capacity of 100 MMBtu/hr. A boiler's design capacity is not necessarily correlated with a boiler's design capacity. Frequently, based upon changes at facilities in which steam needs are reduced, operators do not use boilers near their design capacity. The assumption to correlate 100 tons to 100 MMBtu/hr is inappropriate.

XII. The Schedule for Boilers to Install Low-NOx Controls is Infeasible.

The Final Rule requires compliance testing to be completed no later than May 1, 2026. Final Rule at 36,885; 40 CFR 52.45(d)(1)(i). Since compliance testing requires 30 days, controls must be installed by April 2026. *Id.*; 40 CFR 52.45(d)(1). Even for states in which the Final Rule has not been stayed, this is not enough time to plan, design, approve, permit, install, and test new controls.

EPA's Timing Report estimates the Good Neighbor Plan will result in the installation of pollution controls on over 160 boilers in the same 31-month period. Timing Report at 32. Delays associated with stays of the SIP Disapproval will compress this period for many States.

For the iron and still industry, this will be on top of addressing reheat furnaces and several additional rules currently being promulgated. *See* Ground for Reconsideration VI above. The result is that the regulated community, permitting authorities, and vendors will likely be overwhelmed.

On reconsideration, EPA should reassess the timing needed to comply with the Good Neighbor Plan in light of the unenforceability of the Good Neighbor Plan in many states during judicial review of the SIP Disapproval, more realistic permitting times, and after additional consideration of the multiple obligations arising from other Clean Air Act regulations being promulgated by EPA.

XIII. The Heat Input Requirement for Boilers Does Not Adequately Provide for Outages of Sources of Process Gas.

EPA appropriately exempted from the Good Neighbor Plan a boiler that "receives 90% or more of its heat input from coal, residual oil, distillate oil, natural gas, or combinations of these fuels." Final Rule at 36,884; 40 CFR 52.45(b)(1). In the Final Rule, EPA added "in the previous ozone season," which helps clarify how heat input is to be averaged. *Id.* This addition, however, does not adequately accommodate outages for sources of process gas.

An extended idling of blast furnace operations, for example, can result in periods of blast furnace gas curtailment that could cause a boiler to exceed the 90% heat input threshold in a single ozone season. Bringing a co-fired boiler into the Good Neighbor Plan based on an exceedance of the 90% heat input requirement for a single ozone season, when it will return to normal operation shortly thereafter, makes little sense. Installing controls that are not technically or economically feasible to operate during normal operation is inconsistent with the record and will not be environmentally beneficial. The time it will take to plan, design, permit, install, and test controls will also take longer than the single year such a unit might need to operate on below 10% process gas.

On reconsideration, EPA should accommodate extended outages, either by allowing owners and operators to exclude from the heat input calculation short periods when alternative fuels are not available, or by providing a longer averaging period, such as the three-ozone season average the FIP provides for low-use boilers in 40 CFR 52.45(b)(2).

XIV. EPA Has Not Adequately Explained How Compliance Is Determined for Co-Fired Boilers.

The Final Rule exempts a boiler that "receives 90% or more of its heat input from coal, residual oil, distillate oil, natural gas, or combinations of these fuels." Final Rule at 36,884; 40 CFR 52.45(b)(1). If EPA concludes that they should be regulated, it must provide an appliable emission limit supported by the record. While U. S. Steel agrees that the introduction of process gases can and does interfere with the applicability and effectiveness of controls, it also affects the emission rates a unit can achieve. The Final Rule provides that heat input is to be calculated for natural gas, residual oil, distillate oil, and coal based on a per fuel basis. *Id.*; 40 CFR 52.45(c). EPA conducted no analysis of what emission limit can be achieved at a co-fired unit. If EPA intends to regulate these sources, it needs to have an applicable emission limit that is justified by the administrative record. The absence of any justification in the current record would render applying one of the above emission limits to combustion of process gas arbitrary and capricious.

XV. EPA Should Have Made Facility Wide Averaging Plans Available for Reheat Furnaces and Boilers.

In the Final Rule, EPA introduced the concept of a "Facility-Wide Averaging Plan" to "enable owners and operators of affected units to take costs, installation timing needs, and other considerations into account in deciding which [units] to control." Final Rule at 36,759-60. Facility-wide averaging was not proposed for any industry in the Proposed Rule. As a result, U. S. Steel did not have notice EPA was considering emission unit averaging for the Good Neighbor Plan. EPA made this option available in the Final Rule, but only for emergency engines in the Pipeline Transportation of Natural Gas industry. *Id.* EPA provided no justification for excluding other industries and sources from the option of using an averaging plan.

There is no practical justification for excluding reheat furnaces and boilers at iron and steel mills from being able to use of an averaging plan. U. S. Steel, for example, has long used averaging at emission units to facilitate permitting and maximize compliance efficiencies, including for boilers and reheat furnaces. *See* Attachment A at ¶¶29-31.

On reconsideration, EPA should allow reheat furnaces and boilers at iron and steel mills to take advantage of similar efficiencies and by being able to request a Facility-Wide Averaging Plan for boilers and reheat furnaces that are subject to the Final Rule.

Ground for Stay of the Good Neighbor Plan

EPA has authority to stay the Good Neighbor Plan both pending reconsideration and pending judicial review. First, a stay pending reconsideration can be granted for three months. 42 U.S.C. § 7607(d)(7). Second, EPA has authority under the APA to stay the Good Neighbor Plan pending judicial review.

I. EPA Should Stay the Good Neighbor Plan Pending Reconsideration.

The Clean Air Act provides that, if EPA grants reconsideration of a rule, "[t]he effectiveness of the rule may be stayed during such reconsideration…by the Administrator or the court for a period not to exceed three months." 42 U.S.C. § 7607(d)(7)(B). EPA may also issue a longer stay pending reconsideration under the APA. 5 U.S.C. § 705; 42 U.S.C. § 7607(d)(1). A stay pending reconsideration is justified here.

As discussed above, the Final Rule suffers from critical flaws. It was promulgated in violation of Clean Air Act requirements for many of the States to which it nominally applies. It is based on centrally-relevant information that was not subject to notice and comment, in violation of the procedural requirements of the Clean Air Act. It contains numerous omissions and contradictions that require clarification before the Good Neighbor Plan can reasonably be applied to reheat furnaces and boilers at iron and steel mills. And it overcontrols upwind State emissions, improperly shifting the burden of attainment the NAAQS from downwind States. These issues must be addressed before the FIP is enforced against owners and operators of affected units.

A stay of three months will allow EPA the time needed to reconsider the Good Neighbor Plan and incorporate the above grounds for reconsideration in a decision either to wholly withdraw the Final Rule or to publish a revised FIP that is legally and technically defensible. If additional time is needed, EPA should exercise its authority under the APA to extend the stay to allow sufficient time for full reconsideration and (as discussed below) judicial review.

A stay will also not unduly impact downwind states. The FIP cannot be enforced in ten states during the pendency of the current SIP Disapproval litigation, which will likely not be resolved for the duration of a reconsideration stay. At the same time, it will inequitably affect the remaining States subject to the Good Neighbor Rule, which is inconsistent with the spirit and intent of the Clean Air Act and EPA's stated intent in the Good Neighbor Rule itself to equitably distribute burdens and collectively address downwind impacts. Moreover, emission reductions from the iron and steel industry are not anticipated until 2026, long after a stay pending reconsideration will be completed. As a result, a stay pending reconsideration of the Good Neighbor Plan, and in particular the provisions of the Final Rule applicable to reheat furnaces and boilers at iron and steel mills, will have no impact on downwind attainment or maintenance of the NAAQS.

II. EPA Should Stay the Good Neighbor Plan Pending Judicial Review.

Under the APA, EPA may stay the effective date of the Good Neighbor Plan pending judicial review when "justice so requires." 5 U.S.C. §705. Multiple petitions have already been filed for judicial review, including petitions by Texas, Utah, Ohio, Indiana, West Virginia, and Oklahoma. More are likely, including a petition for judicial review that U. S. Steel is filing contemporaneously with this Petition. These cases are already spread across three circuits, and additional litigation may expand the number of courts further.

The effective date of the Final Rule is August 4, 2023, but the Good Neighbor Plan already cannot be applied in several states because of stays of the SIP Disapproval. A stay pending judicial review will therefore simply reflect the legal reality in those States. Further, the significant legal flaws in EPA's Final Rule discussed above make it likely that judicial review will result in a remand, if not vacatur, of the Good Neighbor Plan. As a result, a stay is strongly supported to avoid the unnecessary expenditure of EPA resources, State resources, and the resources of the public and regulated industries in addressing a FIP that is unlikely to sustained in its current form.

Further, while EPA is not bound to apply the same four-factor analysis used by courts for granting a judicial stay pending review, these factors also support issuance of a stay pending judicial review. Under this standard, the considerations for a stay are:

> 1. whether the stay applicant has made a strong showing that he is likely to succeed on the merits;
>
> 2. whether the applicant will be irreparably injured absent a stay;
>
> 3. whether issuance of the stay will substantially injure the other parties interested in the proceeding; and
>
> 4. where the public interest lies.

Nken v. Holder, 556 U.S. 418, 434, 129 S.Ct. 1749, 173 L.Ed.2d 550 (2009) (citation omitted). These "four considerations are factors to be balanced and not prerequisites to be met." *State of Ohio ex rel. Celebrezze v. Nuclear Regul. Comm'n*, 812 F.2d 288, 290 (6th Cir. 1987).

A. There is a High Likelihood of Success on the Merits.

There is no fixed probability of success the agency must find in applying these considerations. "Ordinarily the party seeking a stay must show a strong or substantial likelihood of success. However, at a minimum the movant must show 'serious questions going to the merits and irreparable harm which decidedly outweighs any potential harm to the defendant if a [stay] is issued.'" *Id.* (*quoting In re DeLorean Motor Company*, 755 F.2d 1223, 1229 (6th Cir.1985)).

As discussed above, the Good Neighbor Plan has substantive and procedural flaws, each of which individually, and more so when combined, demonstrate "a high probability of success on the merits." *Ohio ex rel. Celebrezze v. Nuclear Regul. Comm'n.*, 812 F.2d 288, 290 (6th Cir.1987). Substantively, EPA's Final Rule is based on circumstances that have been completely undermined by recent developments. It was not promulgated in accordance with the Clean Air Act. And was rushed to the point that it violates the core tenets of Cooperative Federalism on which the Clean Air Act, and the NAAQS program in particular, is based. For the iron and steel industry in particular, the FIP lacks a factual basis for supporting the regulation of reheat furnaces and boilers, or a justification for the requirements included in the Final Rule.

Because EPA's FIP is factually and procedurally flawed, and imposes requirements on reheat furnaces and boilers that are incomplete and in many states unenforceable, a challenge for judicial review is likely to prevail on the merits.

B. Absent a Stay, U. S. Steel Will Suffer Imminent Irreparable Harm.

Relevant factors for evaluating the harm which will occur both if the stay is issued and if it is not, the court must look to three factors: the substantiality of the injury alleged, the likelihood of its occurrence, and the adequacy of the proof provided. *Ohio ex re. Celebrezze*, 812 F.2d at 290 (*citing Cuomo v. United States Nuclear Regulatory Commission*, 772 F.2d 972, 974 (D.C.Cir.1985)).

The Final Rule poses substantial and imminent injuries to U. S. Steel. EPA itself warned owners and operators that they would need to "begin engineering and financial planning" as of the date of the *Proposed Rule* to be prepared to meet EPA's implementation timetable. Proposed Rule at 20,036; *see also* Unpublished Order, *Texas v. EPA*, Case No. 23-60069, ECF 269-1, at 22 (citing EPA's FIP timetable as ground for finding irreparable harm). Notwithstanding the fact that it is unreasonable to suggest that significant funds and resources should be used to implement a *proposed* rule that is subject to change (as the Good Neighbor Plan has changed), the Final Rule afforded no relief from this unreasonably short schedule. As discussed above, and in the attached Declaration of Alexis Piscitelli (Attachment A at ¶¶6-10), it allows insufficient time for design, permitting, and installation of controls; likely years less than what will be required. As a result, absent a stay, U. S. Steel cannot afford to wait before it must incur substantial costs on work plans that EPA does not have authority to impose, and on the design, permitting and installation of boiler and reheat furnace modifications that are unnecessary and may be subject to modification in a revised FIP.

As further discussed in the attached Declaration of Alexis Piscitelli, implementation of the Good Neighbor Plan is requiring U. S. Steel to incur immediate and significant costs. Attachment A at ¶¶3, 11-19. The work required by the Good Neighbor Plan will cost between $28 and $46 million at a single facility, excluding testing, monitoring, recordkeeping and reporting costs. Attachment A at ¶15. This cost far exceeds the $7,500/ton marginal cost assumed by EPA in the Final Rule. *See, e.g.* Final Rule at 36,733. These costs are not only unnecessary, they are being imposed without adherence to law. As a result, they constitute a significant irreparable harm to U. S. Steel. *See Thunder Basin Coal Co. v. Reich*, 510 U.S. 200, 220-21 (1994) ("complying with a regulation later held invalid almost always produces the irreparable harm of nonrecoverable compliance costs.") (Scalia, J., concurring in part and in the judgment). The compounding effect of these burdens on top of other regulations pending from EPA further exacerbates to significance of the harm to U. S. Steel. *See* Attachment A at ¶¶20-28.

C. A Stay Will Not Significantly Injury Other Parties.

Emissions reductions from the iron and steel industry are not anticipated to take effect until 2026 at the earlier in the Final Rule. As a result, there can be no appreciable injury to third parties pending judicial review. Moreover, because the Good Neighbor Plan cannot be applied in at least 10 states pending judicial review of EPA's SIP Disapproval, the Good Neighbor Plan is unlikely to apply until the 2024 ozone trading season even without a stay. As a result, a stay pending judicial review of the FIP will not result in any harm.

D. A Stay is in the Public Interest.

As courts have held, there is a public interest in enjoining inequitable conduct and in minimizing unnecessary costs to be met from public coffers. *See, e.g. B & D Land & Livestock Co. v. Conner*, 534 F. Supp. 2d 891, 910 (N.D. Iowa 2008). Here, the public interest supports a stay. As discussed above, EPA's Final Rule is without statutory authority and was promulgated through the inequitable exclusion of public participation on the information central to EPA's action. The result will be costly and needless public expenditures, both by U. S. Steel and the States that must act on the hundreds of permit applications the FIP requires, all while the Good Neighbor Plan is pending judicial review.

While it was an error for EPA to promulgate the Final Rule, EPA can ameliorate the harm of this error by staying the effect of the Good Neighbor Plan until the merits of the issues above can be fully evaluated and addressed.

Conclusion

Because circumstances arising after the close of the public comment period and before the time for judicial review demonstrate that the Good Neighbor Plan must be withdrawn, and because the FIP imposes significant obligations on the iron and steel industry that were not part of the Proposed Rule and that, with further comment, should have been corrected or amended, EPA is obligated to grant reconsideration and should withdraw the Final Rule, either in its entirely or as to reheat furnaces and boilers at iron and steel mills.

Further, to avoid the significant and irreparable harm to U. S. Steel arising from EPA's erroneous promulgation of the Final Rule, EPA should stay 40 CFR 52.43 of the Good Neighbor Plan and 40 CFR 52.45 as applied to the iron and steel industry pending reconsideration and pending judicial review.

Counsel for United States Steel Corporation

ATTACHMENT A – DECLARATION OF ALEXIS PISCITELLI

Before the United States Environmental Protection Agency

In re: Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality Standards, 88 Fed. Reg. 36,654 (June 5, 2023)	)))))	EPA Docket Nos. EPA–HQ–OAR–2021–0668 FRL–8670–02–OAR

Declaration of Alexis Piscitelli

I, Alexis Piscitelli, am over 18 years of age and make the following declaration pursuant to 28 U.S.C. § 1746:

1. I am the Senior Director Environmental for North American Flat Roll. at United States Steel Corporation ("U. S. Steel"), where I am responsible for ensuring compliance and reporting requirements are met in accordance with federal, state and local environmental permits and regulations. I have been employed by U. S. Steel for over 26 years and have advanced through various positions.

2. I am providing this declaration on behalf of U. S. Steel's Petition for Reconsideration and Stay of the United States Environmental Protection Agency's ("EPA's") Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality Standards ("Good Neighbor Plan" or "Final Rule"), 88 Fed. Re. 36,654 (June 5, 2023).

3. As further explained in this declaration, the Final Rule will require immediate actions by U. S. Steel, including either curtailing the operation of reheat furnaces and boilers at U. S. Steel, or the expenditure of millions of

dollars to prepare now for implementation of the Good Neighbor Plan. Either or both of these actions will impose significant additional cost on U. S. Steel. Curtailing or the potential shutdown of the reheat furnaces would impact downstream units and ultimately customers. Curtailing the boilers will reduce electricity generation and increase the demand for outside purchased power, increasing costs and putting additional strain on the grid.

4. The Good Neighbor Plan also omits important flexibilities U. S. Steel uses to effectively and efficiently manage its environmental obligations.

5. This declaration is based on my personal knowledge of facts and information pertaining to U. S. Steel's business and the implications of EPA's Good Neighbor Plan. My knowledge is based on my history with U. S. Steel and analysis U. S. Steel has conducted of the Good Neighbor Plan.

I. <u>The Implementation Schedule for the Good Neighbor Plan is Insufficient</u>

6. In response to the Good Neighbor Plan, U. S. Steel developed a schedule for compliance with the regulatory obligations applicable to U. S. Steel – Gary Works' 84" Hot Strip Mill.

7. Based on our experience with projects of similar size and complexity, the assessment, design, permitting, and installation of low-NOx burners at all four furnaces will not be complete until May 2027, over a year beyond the May 2026 deadline for certification of completion of installation of low-

NOx technology in the Good Neighbor Plan. A copy of the project schedule is included as Appendix A to the attached Barr report (Attachment 1).

8. This schedule conservatively assumes that permitting can be completed in six months. Based on my experience, permitting can take significantly longer, leading to additional delays in completion.

9. U. S. Steel has also had difficulty obtaining vendor quotes for the required work. Consistent with U. S. Steel practice, our contractor, Barr, has attempted to obtain three separate vendor quotes for each technology U. S. Steel is analyzing. Only two firms provided full responses as of July 7, 2023. For one technology, selective non-catalytic reduction ("SNCR"), Barr contacted at least eight vendors but was able to obtain only two estimates. This further demonstrates the need for additional time for implementation of the Good Neighbor Plan, as we anticipate vendors will continue to experience backlogs and supply chain disruptions.

10. U. S. Steel has also had difficulty finding and scheduling qualified union contractors to work on significant projects at our facilities. For example, there are four reheat furnaces at Gary, each will require a significant outage to retrofit the equipment with low NOx burners or the equivalent. We anticipate the availability of qualified union workers will become even a

larger issue with multiple sources being impacted by the Good Neighbor Plan.

II. Implementation of the Good Neighbor Plan Requires U. S. Steel to Incur Immediate and Significant Costs

11. Among other things, the Good Neighbor Plan as promulgated imposes requirements on certain reheat furnaces at iron and steel mills, including the requirement to design a low-NOx burner or alternative low-NOx technology to achieve NOx emission reductions of at least 40% from baseline emission levels measured during performance testing that meets the criteria set forth in the rule. Additional obligations include emissions monitoring, recordkeeping, and reporting requirements.

12. While I agree that requiring a universal, hard limit for reheat furnaces is not appropriate, the requirement to design to meet a minimum 40% reduction of NOx from baseline is not appropriate because it does not take into account what is achievable for each reheat furnace, including what the baseline value actually is – whether, for example, it is 0.12 lb/MMBtu or 0.24 lb/MMBtu, what limits there are on the type of NOx reduction technology that can be used, what fuels the reheat furnace uses, what other pollution control technologies are already in place, or other factors that may make a minimum 40% reduction on some units technically or economically infeasible.

13. Baseline emission level performance testing cannot be completed without significant modification. For example, the reheat furnaces at Gary are very difficult to access. Testing equipment required to meet the USEPA specification cannot be used as currently configured. The facility will require engineered modification to provide access for personnel and equipment to conduct the required testing to establish a baseline for at least a 40% reduction design.

14. Based on the deadlines in the Good Neighbor Plan, which include submitting a completed work plan by August 5, 2024, U. S. Steel has already needed to begin project engineering and design and is already incurring significant costs to complete this work. Without a stay, and while the rule is subject to petitions for review, these costs are expected to substantially increase in the coming months with EPA's aggressive rule implementation schedule.

15. Based on an initial assessment of the costs supported by vendor quotes, I estimate installing low-NOx burners at the four reheat furnaces at U. S. Steel – Gary Works' 84" Hot Strip Mill will cost between approximately $28 million to more than $46 million. *See* Attachment 1 at Table 4-1. This does not include additional operating costs associated with the new equipment or

additional monitoring, performance testing, recordkeeping, and reporting costs associated with the Good Neighbor Plan.

16. This results in an estimated cost effectiveness of between $18,300 and $42,300 per ton NOx removed. Attachment 1 at Table 4-2. This far exceeds $3,656/ton average EPA includes in its Technical Memorandum to support the Final Rule. Summary of Final Rule Applicability Criteria and Emissions Limits for Non-EGU Emissions Units, EPA-HQ-OAR-2021-0668-0956, at Table 6 (March 15, 2023). It also far exceeds EPA's marginal cost threshold of $7,500/ton, the average cost-per-ton range for all non-EGUs of $939/ton to $14,595/ton, and even the $11,000/ton representative EGU retrofit cost EPA used for comparison in the Good Neighbor Plan. Final Rule at 36,746.

17. Without the Good Neighbor Plan, U. S. Steel would not need to incur these costs.

18. A stay of the FIP is necessary to avoid unnecessary costs until a final decision is reached on what obligations should apply to reheat furnaces and boilers at iron and steel mills.

19. Without a stay, U. S. Steel will incur significant and irreparable harm in reconfiguring the hot strip mill at Gary Works to allow for baseline performance testing and implementing the rule's requirements at the Company.

III. The Cumulative Burdens of the Good Neighbor Plan and Other Federal Requirements will Be Substantial and Could Have a Material Impact on Critical Infrastructure, National Security, and U. S. Steel Operations.

20. The U.S. steel industry is responsible for over $520 billion in economic output, supporting over 2 million jobs. It generates over $56 billion in tax revenues annually.

21. In a study conducted under Section 232 of the Trade Expansion Act of 1962 (19 U.S.C. §1862), the U.S. Department of Commerce determined that domestic steel production is essential for national security; and that domestic steel production depends on a healthy and competitive U.S. industry. (See https://www.bis.doc.gov/index.php/other-areas/office-of- technology-evaluation-ote/section-232-investigations).

22. The Cybersecurity & Infrastructure Security Agency has identified the iron and steel industry as a core critical infrastructure industry impacting transportation systems, electric power grid, water systems, and energy generation systems. (See https://www.cisa.gov/topics/critical-infrastructure-security-and-resilience/critical-infrastructure-sectors/critical-manufacturing-sector).

23. Implementation of the Final Rule upon the steel industry, when at the same time implementing new rules upon all facets of domestic steel

manufacturing also potentially jeopardizes thousands of good-paying USW jobs.

24. U. S. Steel is committed to continuing to work with federal partners to develop and implement scientifically sound regulations that effectively and demonstrably benefit the environment.

25. EPA's promulgation of overlapping Clean Air Act regulations without adequate consideration of their interaction undermines these efforts.

26. At the same time that EPA promulgated the Good Neighbor Plan, where it is mandating the installation of controls at reheat furnaces and boilers at iron and steel mills, EPA is proposing new MACT standards at taconite, integrated iron and steel facilities, and coke plants; as well as proposing revised NAAQS standards (e.g., PM2.5) which, combined, could have a material impact on the domestic steel industry, significantly affect the schedule for achieving these requirements, and result in a shortage of available technical support for implementation of these rules.

27. As noted above, U. S. Steel is already having difficulty obtaining qualified contractors and vendor quotes. These additional rules will exacerbate the problem.

28. EPA has also announced that it anticipates proposing reconsideration of the current ozone NAAQS in April 2024. As a result, EPA may be revising the

ozone NAAQS at the same time that the Good Neighbor Plan is requiring U. S. Steel to install pollution controls to address the current standards. Piecemealing these two rules, for which implementation will likely overlap, is problematic and inappropriate, as U. S. Steel could quite possibly be compelled to install additional or different controls on the same emission units following EPA's reconsideration. This would result in significant waste and could be avoided if EPA withdraws the Good Neighbor Plan and takes the two years allowed by the Clean Air Act for implementation of a revised FIP.

IV. <u>Importance of Facility-Wide Averaging to U. S. Steel</u>

29. U. S. Steel uses – and EPA, as well as other regulatory agencies, have allowed – emissions unit averaging where appropriate to effectively and efficiently satisfy regulatory obligations.

30. For example, at U. S. Steel – Great Lakes Work, boilers are permitted by boiler house, allowing averaging across multiple boilers serving the same or similar functions. At U. S. Steel – Granite City Works, Slab Furnace Nos 1-4 are subject to a single NOx limit, allowing averaging across all four reheat furnaces.

31. Allowing similar averaging in the Good Neighbor Plan would allow U. S. Steel to continue to benefit from the coordinated management of these emission units without sacrificing overall emissions performance.

V. <u>Conclusion</u>

32. In my opinion, the schedule set forth in the Good Neighbor Plan is not realistic and underestimates the time needed for compliance by at least a year. If emission units cannot achieve compliance by the scheduled deadlines and the deadlines are not stayed or extended, those emission units will be required to curtail operation. As a result. U. S. Steel is already required to incur substantial costs in order to prepare for the upcoming Good Neighbor Plan deadlines despite pending petitions for reconsideration and judicial review that may affect the applicability of the Good Neighbor Plan and the obligations that it imposes on reheat furnaces and boilers.

33. A stay of the Good Neighbor Plan will mitigate these harms.

I declare, under penalty of perjury, that the foregoing is true and correct.

Executed on August 4, 2023.

Technical Memorandum

To: Louis Covelli (U. S. Steel)
From: Dane Jensen
Subject: 84" Hot Strip Mill Reheat Furnaces Good Neighbor Plan NO_X Emissions Controls Evaluation
Date: August 3, 2023
Project: 14451044.00
c: Thomas Ruffner, David Hacker, Kendra Jones, Christopher Hardin, Brett Tunno (U. S. Steel), Ryan Siats (Barr Engineering Co.)

Executive Summary

The U.S. Environmental Protection Agency (EPA) is taking action under the "good neighbor" or "interstate transport" provision of the Clean Air Act, with rulemaking that will take effect on August 4, 2023. The Good Neighbor Plan rulemaking under Docket ID No. EPA–HQ–OAR–2021-0668 requires emission reductions for affected facilities at U. S. Steel – Gary Works (USS), namely the 84" Hot Strip Mill (HSM) reheat furnaces (RHFs). The draft rulemaking requires a 40% NO_X reduction for RHFs. Barr was tasked with assessing the technical feasibility of selective catalytic reduction (SCR) and selective non-catalytic reduction (SNCR) technologies, reviewing facility impacts of feasible NO_X controls including Low NO_X Burners (LNB), estimating costs and the cost effectiveness of feasible NO_X controls, and summarizing annual compliance testing costs.

The key findings of the HSM NO_X evaluation include:

- SCR is not technically feasible for the RHFs.
- SNCR is not technically feasible for the RHFs. There are operating conditions where the flue gas temperatures are expected to be outside the required SNCR reaction range.
- The compliance schedule in the draft rulemaking is insufficient to allow for installation of NO_X control technologies given requirements for baseline emissions testing, permitting, and availability of equipment vendors, mill wrights, engineering staff, etc.
- LNBs would require furnace upgrades, new flame safety equipment, and other facility modifications to accommodate this technology.
- The cost effectiveness of LNBs ranges from \$18,300 to \$42,300 per ton of NO_X removed.
- Annual performance testing costs for the RHFs are estimated to be \$13,300 to comply with the monitoring requirements of the Good Neighbor Plan.

Additional detail on each finding is summarized by Section below.

1 Good Neighbor Rule Regulatory Applicability

The regulatory applicability of the RHFs to the Good Neighbor Plan is described below.

40 CFR 52.43(b) states "*The requirements of this section apply to each new or existing reheat furnace at an iron and steel mill or ferroalloy manufacturing facility that directly emits or has the potential to emit 100 tons per year or more of NO_X on or after August 4, 2023, does not have low-NO_X burners installed, and is located within any of the States listed in § 52.40(c)(2), including Indian country located within the borders of any such State(s).*" The four reheat furnaces located at the Gary Works HSM all exceed a 100 tpy NO_X potential to emit, are in a state listed in §52.40(c)(2), and do not have LNB installed. Therefore, the RHFs are subject to the provisions of 40 CFR 52.43 and must achieve a 40% NO_X reduction from baseline conditions by the 2026 ozone season.

2 Technical Feasibility of SNCR and SCR

The technical feasibility of SNCR and SCR for the RHFs is discussed below. Figure 1 marks locations #1, #2, and #3 that will be referred to in the SNCR and SCR feasibility discussions for reference.

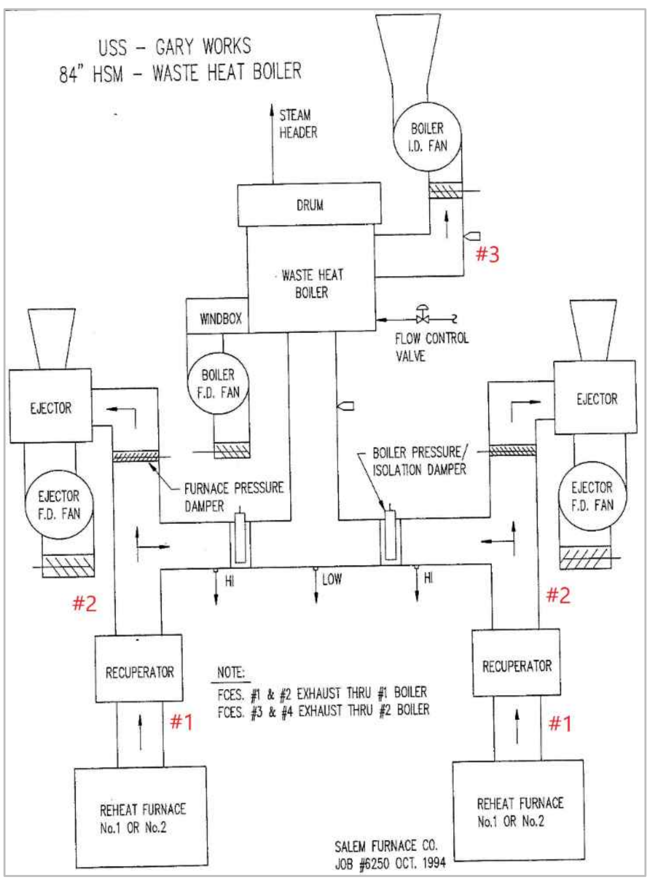

Figure 1 SNCR and SCR Feasibility Evaluation Locations

2.1 SNCR

SNCR involves the injection of ammonia or urea into a flue gas stream where the reagents react with NO_X to form elemental nitrogen. SNCR reactions require the flue gas temperature to be within a 1,600° Fahrenheit (F) to 2,100°F temperature range, with 1,800°F being ideal.

The only suitable SNCR injection location within the appropriate temperature location is #1, namely the outlet of the RHFs prior to the recuperator (refer to Figure 1). USS provided temperature data for this location and typically temperatures range from 1,600 to 1,930°F when operating. However, there are concerns about the viability of the data. A large portion of the data Barr received shows failed thermocouples or unreliable data trends. Figure 2 and Figure 3 show the Furnace 1 East and Furnace 4 East uptake temperatures, respectively, as an example of the sporadic data. It is unclear what represents "real" data vs. what is noise or failed thermocouples.

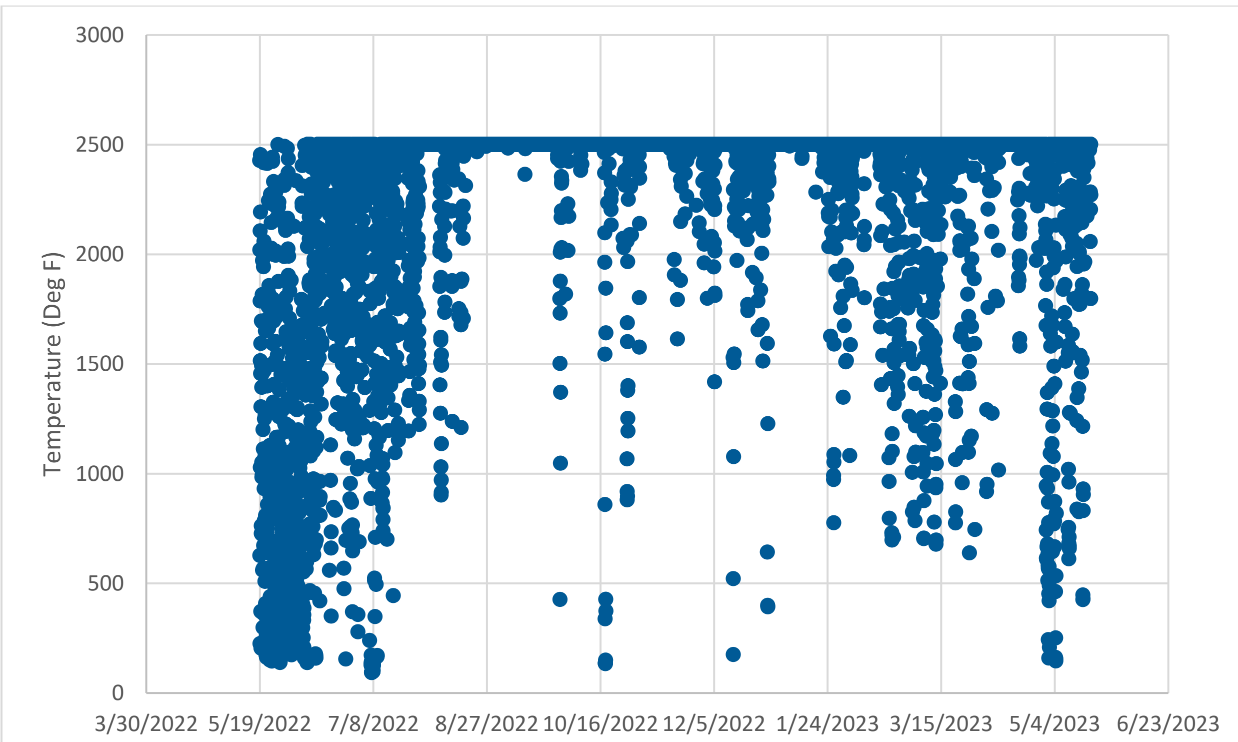

Figure 2 Furnace 1 East Uptake Temperatures Vs. Time

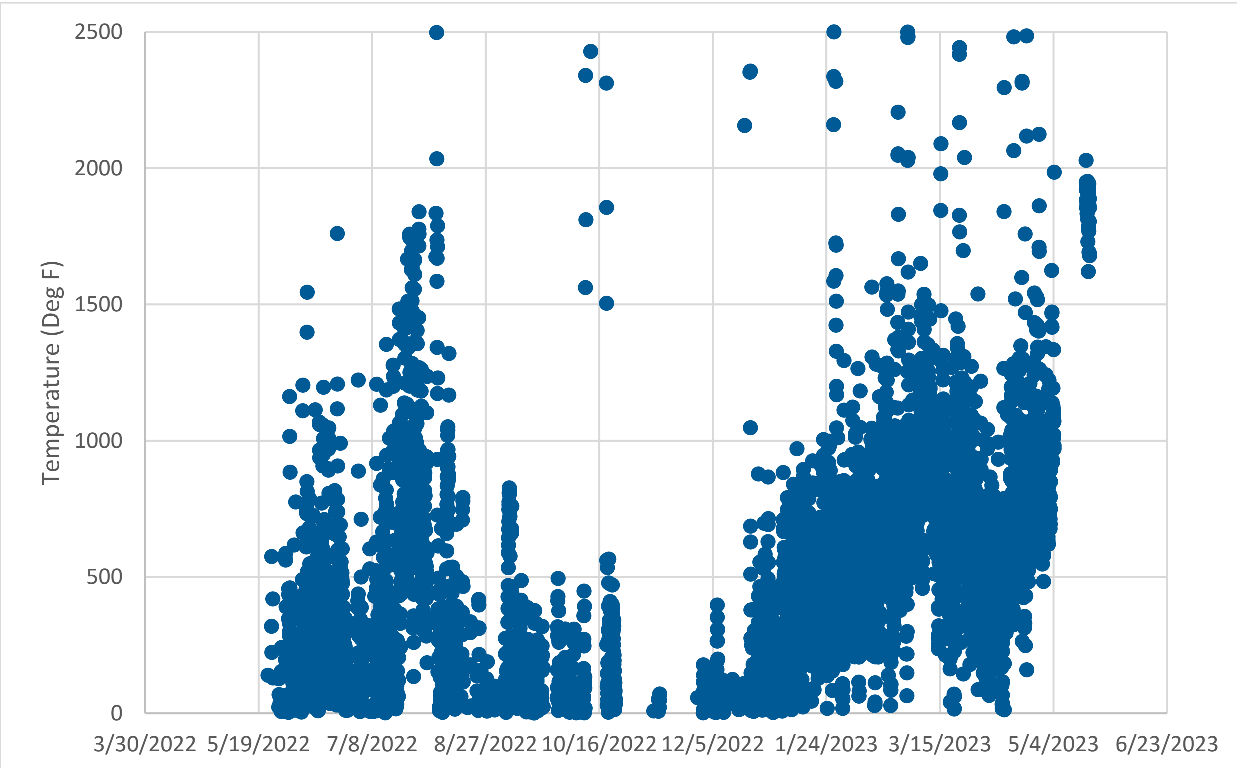

Figure 3 Furnace 4 East Uptake Temperatures Vs. Time

Another important design factor is residence time in the ducting with the high SNCR reaction temperatures. Vendors believe that there should be sufficient residence for SNCR in this application based on their review of USS data.

However, there are operating conditions where the flue gas fails to meet the minimum SNCR reaction temperatures, rendering SNCR infeasible. The Good Neighbor Plan requires a 40% NO_X reduction. Therefore, SNCR cannot sufficiently control NO_X at all times under all operating conditions. This is especially important during hot-standby conditions where fuel firing occurs, but USS expects the uptake temperatures to be below minimum SNCR requirements. In addition, a vendor stated that a feasibility study would be required to provide any sort of NO_X reduction guarantee. While SNCR is feasible during some operating scenarios, it cannot provide the needed consistent NO_X reduction for compliance purposes.

2.2 SCR

SCR reduces NO_X emissions with ammonia or urea injection in the presence of a catalyst. The catalyst enables the de- NO_X reactions to proceed at a lower temperature than SNCR. Most SCR catalysts must be at 450° F to 800° F for proper SCR operation based on vendor discussion and the EPA Control Cost Manual[1]. Each location for SCR from Figure 1 above was reviewed for SCR feasibility.

Location #1 – the temperatures at location #1 are too high (i.e., 1,600 to 1,930°F), so SCR is not technically feasible.

Location #2 – Waste heat temperatures exiting the recuperator are also too high for SCR. From May 2022 to May 2023, the average waste heat temperature was over 900°F, with temperature spikes exceeding 1,150°F. This is well above the optimal SCR range noted above. USS is aware that there are high-temperature applications of SCR on simple cycle combustion turbines in the temperature ranges of 850 to 1,000°F with vendors stating that 1,100°F would be the absolute maximum allowable temperature. However, high temperature SCR systems are significantly more costly due to special catalyst formulations and the catalyst life expectancy tends to shorten significantly, requiring more frequent changes that may inhibit production. As noted above, the high temperature spikes above 1,150°F would be above the maximum allowable temperature range making SCR infeasible for this location. In addition, high temperature SCR applications for simple cycle combustion turbines often use tempering air to reduce exhaust temperatures to suitable levels for normal SCR reaction temperatures. However, the use of tempering air is impractical for this application because the exhaust flows exiting the recuperator are quite large (i.e., more than 800,000 acfm) meaning that large amounts of make-up air would be required to sufficiently cool the exhaust flow to acceptable SCR reaction temperatures. The exhaust handling equipment cannot accommodate additional flow, and all the areas surrounding the recuperator outlet ductwork are extremely cramped with no reasonable way to incorporate additional cooling air, let alone provide sufficient residence time for mixing. In addition, tempering air would dilute the NO_X inlet concentration reducing the control equipment effectiveness. Further, SCR reactors for airflows of this magnitude are very large requiring a significant footprint. As noted above, the spacing surrounding this location is cramped, and it would be essentially impossible to shoe-horn a SCR reactor in place for this application. Also, it is not known if the existing building infrastructure could support additional weight above the furnace after the recuperator. Therefore, SCR is not technically feasible for location #2.

Location #3 – Exhaust temperatures at the exit of the waste heat boilers (WHBs) range from approximately 450 – 925°F. This mostly fits the SCR reaction temperature requirements. While the temperature profile may be satisfactory, it is impractical to install a SCR reactor at this location. Only a portion of the RHF exhaust is routed through the WHBs, meaning that the entire gas stream would not be treated. In addition, there are times when only the ejector stack is used, and no exhaust is routed through the WHBs. Therefore, there is no way to guarantee any consistent level of NO_X reduction with SCR at this location with incomplete or no RHF exhaust treatment, and would jeopardize compliance with the Good Neighbor Plan limits. Further, the variable exhaust flow through the WHBs would significantly complicate any SCR reactor design and may make it difficult to properly inject sufficient reagents and maintain proper mixing for all operating conditions. Further, spaces surrounding the outlet of the WHBs are very

[1] https://www.epa.gov/sites/default/files/2017-12/documents/scrcostmanualchapter7thedition_2016revisions2017.pdf

cramped leaving no viable location for a sizeable SCR reactor. Therefore, SCR is not practical or technically feasible for Location #3.

3 Facility Impacts of New NO_X Controls

According to discussions with vendors, LNBs will not impact production rates and burner vendors are willing to provide this guarantee. While not inherently challenging to LNBs, there are significant concerns about the schedule and the implementation period proposed in the Good Neighbor Plan (i.e., reductions must be achieved by the 2026 ozone season). As a result of this rulemaking, USS will need to conduct and obtain results from baseline emissions testing prior to submission of an application to modify the facility's operating permit to integrate either control technology. In addition, there are numerous facilities and industries nationwide that will be required to install controls for compliance. Therefore, USS is concerned that there will be insufficient resources for performance testing, permitting, engineering, equipment suppliers, equipment fabricators, and mill wrights that will allow USS to install necessary controls for compliance, much less all other affected facilities nationwide.

Schedule concerns have been evident during the development of this memo as Barr has attempted to obtain three separate vendor quotes. However, only two firms have provided costs for both LNB August 3, 2023. One LNB vendor failed to provide a quotation to USS even after stating that they could provide a new quote, so a 2020 cost estimate was scaled to 2023 dollars for this effort. This further demonstrates the need for additional time for implementation of this rule given vendor backlogs and unexpected supply chain disruptions. In addition, USS estimated a schedule based on engineering experience for the installation of LNBs (included as Appendix A to this memo) showing that there is insufficient time in the draft rule to install controls on all four RHFs and meet the compliance deadline.

Facility impacts for LNB installations are listed below:

- To accommodate new burners, USS will need to upgrade the furnace so that sufficient pressure can be maintained at the burners for safe and reliable operation.
- New National Fire Protection Association combustion safety equipment will be installed with new burners.
- Fuel pressure regulators will require modifications to increase fuel pressure at the burners.
- Some burner vendors require new combustion air fans complicating the overall design and installation.

4 Cost Estimates of New NO_X Controls

Barr and USS evaluated the costs for LNBs below for the RHFs. A detailed breakdown of capital equipment and installation costs has been prepared by USS for LNB based on vendor quotes and engineering experience. Table 4-1 summarizes capital costs for all furnaces for each vendor.

Table 4-1 Total Capital Investment Summary for LNB by Vendor (Total Cost for All Four Furnaces)

Vendor	Total HSM Capital Investment ($)
Vendor 1	$28,400,000
Vendor 2	$32,300,000
Vendor 3 (2020 Scaled Estimate)	$46,400,000

Detailed cost-effectiveness calculations for LNB are included in Appendix B. Table 4-2 summarizes the control costs for each LNB vendor.

Table 4-2 NO_X Control Cost Summary for LNB Vendors (Individual Furnace Cost)

Vendor	Total Capital Cost ($)	Annualized Cost ($/yr)	NO_X Reduction (tpy)	Cost Effectiveness ($/ton NO_X Removed)
Vendor 1	$7,112,000	$1,156,000	63	$18,300
Vendor 2	$8,073,000	$1,294,000	31	$42,300
Vendor 3 (2020 Estimate)	$11,590,000	$1,800,000	61	$29,500

5 Annual Performance Testing Cost Estimate

USS sought a performance testing bid for annual reheat furnace testing. The annual RHF performance testing costs are estimated to be $13,322. These costs and other miscellaneous costs such as recordkeeping and reported are not included in the cost-effectiveness evaluation in Appendix B.

6 Conclusions and Recommendations

The key findings of the HSM NO_X evaluation include:

- SCR is not technically feasible for the RHFs.
- SNCR is not technically feasible for the RHFs. There are operating conditions where the flue gas temperatures are expected to be outside the required SNCR reaction range.
- The compliance schedule in the draft rulemaking is insufficient to allow for installation of NO_X control technologies given requirements for baseline emissions testing, permitting, and availability of equipment vendors, mill wrights, engineering staff, etc.
- LNBs would require furnace upgrades, new flame safety equipment, and other facility modifications to accommodate this technology.
- The cost effectiveness of LNBs ranges from $18,300 to $42,300 per ton of NO_X removed.
- Annual performance testing costs for the RHFs is estimated to be $13,300 to comply with monitoring requirements of the Good Neighbor Plan.

Low NOx Burners (LNB) - Vendor 3	40%	91.7	61.1	$11,593,945	$1,799,972	$29,455

a - Calculated control efficiencies are not based on EPA certified performance test methods due to lack of access to appropriate test locations. Therefore, the control efficiencies may not appropriately represent what can be achieved from existing baseline conditions and the required reductions in the Good Neighbor Plan may not be feasible.

USS Gary - HSM NOx Controls Evaluation
Appendix B - Low NOx Burner Cost Estimates (All Furnaces)
Vendor 1 Estimate

Burners Ultra-Low Nox Burners
New burners will fit inside existing bodies (plug & play)

Flame safety included:
Covert the soak zone to a supervised system to bring the soak zone above auto-ignition
16 New Soak Burners, Direct Spark Ignition, Flame Rod, Transformer, Ignition Cable, Necessary Gas and Air Valves
Double Block Valves for 40 Soak Burners
New NFPA Compliant Main Fuel Train
New NFPA Compliant Pilot Train - Required for Cold Start Operation in Bottom Heat.
To Accommodate Flame Supervision in the Soak Section and Cold Start Capabilities in the Bottom Heat Section.

Included in cost scope:
Upgrades to combustion air system and recuperators
NG piping replacement as required - restricted piping... coke oven gas remediations
Upgrades to Level 0/1 components
Refractory

USS Gary - HSM NOx Controls Evaluation
Appendix B - Low NOx Burner Cost Estimates (All Furnaces)
Vendor 1 Estimate

Vendor 2 Estimate

Burners New burners
All four burner walls will be reworked to incorporate the necessary converging tile for the required air injection velocity.
Need to replace combustion air fans

Flame safety included:
Four auxiliary side fired burners to bring the soak zone above auto-ignition.
Replacement of the burner bodies in the bottom heat zone to accept a fully compliant piloted ignition system
Addition of injectors only to the top heat and top and bottom preheat zones that will be interlocked to 1400 °F permissive.
Proof of purge and low fire switches will be installed on existing air metering orifice plates
Safety PLC is included to perform the necessary flame monitoring and natural gas path select functionality

Included in cost scope:
Upgrades to combustion air system and recuperators
NG piping replacement as required - restricted piping... coke oven gas remediations
Upgrades to Level 0/1 components
Refractory

Burners New burners
Moderate shell steel and refractory port modifications
The combustion air blower will be replaced with higher pressure fans
existing recuperator, zone orifice plates and flow control valves.
Burner drop ductwork will need to be modified as required to connect to the new burners.
New burner expansion joints will be provided along with new burner isolation valves.
Gas piping from the gas train to the burners will remain in place, and existing orifice plates and flow control valves will remain in service
Piping modification to suit the new burners will be made at the burner drops
A new level 1 control system, including new PLC hardware, remote I/O panels, HMI screens is included.

Flame safety included:
Gas train for the furnace must be modified to comply with the latest NFPA-86 standards
The combustion system will be designed to use the top and bottom heat zones as the light-up zones
The top and bottom preheat zones will be ignited when the zones are above auto-ignition bypass temperature
The furnace will be provided with new purge and safety checks for proper ignition sequence as mandated by the NFPA.
Ignition burners will have spark ignited pilot burners with UV detector type flame supervision
A burner management system panel will be included to house the electronic components

Re: Petition for Reconsideration and Stay of the Final Rule: Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, EPA-HQ-OAR-2021-0663; EPA-R05-OAR-2022-0006; 88 Fed. Reg. 9,336 (February 13, 2023)

Dear Administrator Regan:

On behalf of our clients, ALLETE, Inc. d/b/a Minnesota Power; Northern States Power Company – Minnesota d/b/a/ Xcel Energy; Great River Energy; Southern Minnesota Municipal Power Agency; Cleveland-Cliffs, Inc.; and United States Steel Corporation (collectively the “Minnesota Good Neighbor Coalition”), please find enclosed a petition for reconsideration and stay of the disapproval of “prong 2” of Minnesota’s State Implementation Plan (“SIP”) in the United States Environmental Protection Agency’s final rule: Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, EPA-HQ-OAR-2021-0663; EPA-R05-OAR-2022-0006; 88 Fed. Reg. 9,336 (February 13, 2023).

Please contact me with any questions you may have.

Sincerely,

/s/ Douglas A. McWilliams

Petition for Reconsideration and for Stay of the Air Plan Disapprovals for Interstate Transportation of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards

ALLETE, Inc. d/b/a Minnesota Power; Northern States Power Company – Minnesota d/b/a/ Xcel Energy; Great River Energy; Southern Minnesota Municipal Power Agency; Cleveland-Cliffs, Inc.; and United States Steel Corporation (collectively "Petitioners") respectfully request that the United States Environmental Protection Agency ("EPA") reconsider and stay the portion of its final rule Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 Fed. Reg. 9336 (February 13, 2023) (the "SIP Disapproval") that disapproves Minnesota's state implementation plan ("SIP") for interstate transport for "prong 2" of Clean Air Act ("CAA") § 110(a)(2)(D)(i)(I), 42 U.S.C. § 7410(a)(2)(D)(i)(I).

Minnesota is uniquely situated in the SIP Disapproval. In EPA's February 13 action, Minnesota's SIP was approved for "prong 1"[1] based on EPA's finding that Minnesota does not contribute significantly to nonattainment in any downwind state. Minnesota's SIP was disapproved for "prong 2," with EPA finding that Minnesota was linked to interference with maintenance of a single downwind maintenance-only receptor. EPA has subsequently found in its promulgation of an ozone transport federal implementation plan ("FIP") that Minnesota was not linked to any downwind non-attainment or maintenance-only receptor when modeled for 2026.

Based on the best evidence available in 2018 when Minnesota submitted its SIP to EPA for approval (and on April 1, 2020 when EPA had a statutory obligation to approve or deny the Minnesota SIP), Minnesota was ***not*** linked to interference with attainment or maintenance in any downwind state. But, EPA did not timely act on the Minnesota SIP, and then it moved the goal posts. Based on new modeling and emission data EPA developed years later, (the "2016v2" modeling platform) EPA proposed to find that Minnesota was linked to two downwind maintenance-only receptors due to a modeled impact of less than 1 ppb at each receptor. In the

[1] As discussed on page 4 *infra*, EPA has divided the Good Neighbor obligation set out in Clean Air Act ("CAA") § 110(a)(2)(D), 42 U.S.C. § 7410(a)(2)(D), into two "prongs." The obligation to prohibit sources from emitting air pollutants in an amount which will "contribute significantly to nonattainment" is sometimes referred to as "prong 1," and the obligation to prohibit sources from emitting air pollutants in an amount which will "interfere with maintenance" as "prong 2."

final SIP Disapproval, EPA again revised its emissions data and modeling (the "2016v3" modeling platform) and now finds that Minnesota is linked in 2023 to only a single maintenance-only monitor, at a maximum contribution of 0.85 ppb. Further, EPA has since released updated modeling results for 2026 that show that this same monitor will be in attainment without any material reduction of emissions from Minnesota. As a result, after five years of updates, EPA's modeling results support the same conclusion that Minnesota reached in 2018, namely that additional emissions reductions are not needed to prohibit emissions in Minnesota that will contribute significantly to nonattainment, or interfere with maintenance of, the 2015 8-hour ozone NAAQS in any downwind state. We ask that EPA grant this petition for reconsideration to do what it should have done in 2018—Approve the Minnesota SIP.

The approvability of Minnesota's original SIP submittal is corroborated by two additional pieces of information that were not available during the public comment period for the proposed SIP disapproval or prior to EPA's release of its 2016v3 modeling in 2023. First, EPA's 2016v3 emissions inventory materially overstates Minnesota's 2023 NOx emissions; for example, it incorrectly assumes over 2,800 tons of NOx from an electric generating facility that has been idled since 2019 and is projected to have zero emissions in 2023. By merely correcting the projected actual NOx emissions, Minnesota has already achieved more NOx reductions than EPA's FIP would require of Minnesota. This effectively confirms Minnesota's step 3[2] conclusion in its 2018 SIP that no additional permanent or enforceable measures were needed beyond those already implemented by the state.[3]

Second, as EPA has recognized, its CAMx modeling is subject to significant bias in areas of complex meteorology, including the water/land interface occurring at the sole maintenance monitor that EPA has linked to Minnesota emissions. While EPA released with the final SIP Disapproval a review of this localized bias risk for southern Lake Michigan, that review was materially flawed and does not address the significant over-prediction bias occurring on the precise days EPA selected for use in evaluating Minnesota's SIP. As a result, EPA's general conclusion that adjusting for bias will not affect the outcome of its SIP reviews, does not apply to its review of the Minnesota SIP. To the contrary, adjusting for material bias results in the sole maintenance-only monitor to which Minnesota was linked by EPA becoming an attainment monitor in 2023. In other words, eliminating high-bias days alone completely addresses EPA's objection to Minnesota's 2018 SIP and eliminates Minnesota at Step 1 of EPA's four-step analysis.

Reconsideration is appropriate to make the above corrections to the emissions inventory and to account for modeling bias. After incorporating this new material information into the SIP analysis, we believe that EPA will conclude as we have that Minnesota's original 2018 SIP determination that it is not having a downwind impact on attainment or maintenance that requires additional permanent and enforceable measures was correct and warrants approval of

---

[2] *See* page 4 *infra* for the list of four steps in EPA's 4-step framework for evaluating Good Neighbor SIP submissions.

[3] *See* Minnesota's 110(a)(1) and 110(a)(2) "Infrastructure" State Implementation Plan requirements for the National Ambient Air Quality Standards for Ozone, Promulgated in 2015, EPA-R05-OAR-2022-0006-0005, at 12 (October 1, 2018) ("2018 SIP").

the Minnesota SIP. Reconsideration is also appropriate to address a significant procedural flaw in the finalization of the SIP Disapproval. Specifically, the SIP Disapproval relies on information that was not available to EPA, Minnesota, or any other interested parties until 2023, well past the period for Minnesota's SIP submission and EPA's statutory deadline to approve Minnesota's SIP. While EPA has an obligation to use the best available evidence in making its regulatory decisions, that obligation is not unbounded and cannot be used to circumvent the procedures set forth in the Clean Air Act. When Minnesota timely submitted a SIP that is approvable based on the information known at the time, EPA had an obligation to approve the SIP. The Act does not allow EPA unfettered discretion to delay approval until new information becomes available, and then move the goalposts. For States that have done their part to invest resources in developing a timely and approvable SIP, EPA has a statutory obligation to act. EPA may still consider new scientific data and modeling after the statutory deadline, but there is a separate administrative process available to EPA that respects the State's SIP process. Minnesota should have an approved SIP and EPA should be considering whether new information is sufficiently material to require a "SIP call" pursuant to CAA § 110(k)(5), 42 U.S.C. § 7410(k)(5), to give Minnesota the opportunity to revise its SIP given the new available information. Having chosen to use this new information to disapprove prong 2 of Minnesota's SIP instead, EPA deprived Petitioners, the State, and other interested parties of significant procedural protections and opportunities for public input that were required by the Clean Air Act. Granting reconsideration allows EPA the opportunity to cure the procedural flaw that its final action is based on material information that has not been subject to the notice and comment process.

Given that new information was made available after the close of the public comment period, but before the time for judicial review, that such information actually undermines EPA's basis for disapproving prong 2 of Minnesota's 2018 SIP in the SIP Disapproval, and reconsideration would address the harms caused by significant procedural defects in the SIP Disapproval, Petitioners respectfully request that EPA grant reconsideration for the purpose of reviewing this new information and approving prong 2 of Minnesota's 2018 SIP.

Further, since the disapproval of prong 2 of Minnesota's SIP, and the continued implementation of EPA's subsequently-issued FIP, will cause irreparable harm to Petitioners, we request that EPA grant a stay of the disapproval of prong 2 of Minnesota's SIP pending reconsideration and pending judicial review, which will also address the irreparable harm caused by EPA's FIP.

I. Background

On October 1, 2015, EPA promulgated a revised primary and secondary 8-hour ozone NAAQS of 70 ppb. This created a requirement under the CAA for states to submit revised SIPs to EPA by October 1, 2018.[4] SIPs were required to meet the applicable requirements of CAA § 110(a)(2), 42 U.S.C. § 7410(a)(2), including an obligation, sometimes referred to as a "Good Neighbor" obligation, that the SIPs:

[4] 42 U.S.C. § 7410(a)(1).

> (D) Contain adequate provisions—
>
> > (i) prohibiting, consistent with the provisions of this subchapter, any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will—
> >
> > > (I) contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any such national primary or secondary ambient air quality standard, …

42 U.S.C. § 7410(a)(2)(D). The obligation to prohibit sources from emitting air pollutants in an amount which will "contribute significantly to nonattainment" is sometimes referred to as "prong 1," and the obligation to prohibit sources from emitting air pollutants in an amount which will "interfere with maintenance" as "prong 2," of the Good Neighbor obligation.

While EPA has never promulgated regulations imposing more specific interstate transport requirements than what is contained in the statutory text, EPA has developed a 4-step framework that it stated the agency would use to evaluate a state's compliance with its Good Neighbor obligation. Namely:

(1) Identify monitoring sites that are projected to have problems attaining and/or maintaining the NAAQS (i.e., nonattainment and/or maintenance receptors);

(2) identify states that impact those air quality problems in other (i.e., downwind) states sufficiently such that the states are considered ''linked'' and therefore warrant further review and analysis;

(3) identify the emissions reductions necessary (if any), applying a multifactor analysis, to eliminate each linked upwind state's significant contribution to nonattainment or interference with maintenance of the NAAQS at the locations identified in Step 1; and

(4) adopt permanent and enforceable measures needed to achieve those emissions reductions.[5]

Minnesota took a notably conservative approach in its SIP. First, in EPA's Transport Memo, EPA recognized that its four-step framework was not binding, and offered that states "have flexibility to follow this framework or develop alternative frameworks."[6] Despite this flexibility, Minnesota adopted EPA's framework for its SIP.[7] Second, EPA made clear, in the

[6] *Id.*

[7] 2018 SIP at 5.

Transport Memo and in a separate memorandum published later that year, that states did not need to adopt EPA's suggested 1% threshold for determining significant contributions and interference with maintenance at step 2.[8] Here too, Minnesota did not exercise this flexibility, and chose instead to use EPA's preferred approach.[9] Third, EPA guidance offered states flexibility regarding how to determine which downwind monitors should be considered maintenance receptors.[10] Again, Minnesota followed EPA's suggested approach.[11] In other words, while Minnesota was not required to, it followed EPA's own framework and did not rely on additional flexibilities to demonstrate that it had satisfied its Good Neighbor obligations.[12]

Minnesota also used the best information available at the time to determine its Good Neighbor obligations. Specifically, Minnesota used EPA's own modeling and modeling developed by the Lake Michigan Air Directors Consortium ("LADCO") to identify monitoring sites projected to have problems attaining or maintaining the 2015 ozone NAAQS in 2023.[13] It then projected the state's own contributions to those nonattainment and maintenance monitors using both sets of results.[14] Both EPA's and LADCO's modeling showed that Minnesota would contribute less than 1 percent of the NAAQS to all downwind receptors, with a highest receptor contribution from either model of 0.45 ppb.[15] Thus, following EPA's 4-factor framework, and using EPA's own modeling and proposed threshold, Minnesota demonstrated that it was not contributing significantly to, or interfering with maintenance of, the 2015 ozone NAAQS in any downwind state.

This alone would have been sufficient to satisfy Minnesota's Good Neighbor obligation. Minnesota also, however, included in its SIP submission a "step 3" analysis demonstrating that Minnesota emissions of ozone precursors had been reduced from 2002 through 2015 and would be further reduced by emission limitations and reductions required by other programs.[16] Under this step 3 analysis, Minnesota demonstrated that, even if the state were having more than an insignificant impact on downwind receptors (as EPA now asserts), Minnesota's existing glidepath of emissions reductions still supported a finding that no further emission control measures would

[11] 2018 SIP at 5.

[12] Minnesota, of course, could have taken a different approach, and might have used some of these flexibilities, had EPA indicated during the statutory review period that it was considering disapproving prong 2 of Minnesota's SIP.

[13] 2018 SIP at 5-9.

[14] *Id.*

[15] *Id.* at 8-9.

[16] *Id.* at 9-12; *see also id.* at 13.

be needed to address this impact. EPA did not meet its obligation to approve or deny Minnesota's complete and approvable SIP within 12 months of submittal.

Approximately three years after EPA's deadline to approve the Minnesota SIP, EPA proposed to disapprove Minnesota's SIP on February 22, 2022, along with SIPs from 18 other states.[17] EPA did not identify a technical error in Minnesota's submission or any inconsistency with the Good Neighbor requirements, or even EPA's own framework. In fact, EPA recognized that "the modeling the MPCA used relied on the most recently available EPA modeling at the time the state submitted its SIP submittal."[18] Nonetheless, EPA proposed to reject Minnesota's SIP because EPA chose to rely "on the Agency's most recently available modeling, which uses a more recent base year and more up-to-date emissions inventories, to identify upwind contributions and 'linkages' to downwind air quality problems in 2023 using a threshold of 1 percent of the NAAQS." *Id.* Based on this data, EPA proposed to reject Minnesota's conclusion that it was not linked to a downwind receptor, and to find instead that Minnesota was linked to two maintenance monitors in Cook County, Illinois, one with a maximum contribution of 0.97 ppb and the other 0.79 ppb.[19]

On February 13, 2023, EPA published the SIP Disapproval. In its final rule, EPA approved Minnesota's SIP as to "prong 1" but disapproved Minnesota's SIP as to "prong 2."[20] Rather than use the emissions data and modeling available to Minnesota in 2018, or even emissions data and modeling available at the time of the proposed SIP disapproval, EPA made a number of additional updates to its emissions inventories and model design to construct a new 2016v3 emissions platform, which it used to generate new air quality modeling without seeking public comment to allow affected party input to help the agency assess the accuracy of the new information utilized in the modeling.[21] Minnesota was now no longer linked to two downwind receptors. It was now linked to only a single maintenance-only receptor, at a maximum contribution of 0.85 ppb for 2023.[22]

While EPA also conducted updated modeling for 2026, it did not release this information in the docket for the SIP Disapproval, stating it was "not applicable" and "not used in this final action."[23] EPA subsequently made these results available, however, on EPA's website for its Federal Implementation Plan ("FIP") for 23 states, including Minnesota.[24] Based on EPA's modeling for 2026, Minnesota is not linked to any downwind nonattainment or maintenance-only receptor. In fact, based on EPA's modeling, the sole maintenance-only receptor Minnesota was linked to in 2023 is in attainment by 2026, and Minnesota's largest contribution to any

[17] Air Plan Disapproval; Illinois, Indiana, Michigan, Minnesota, Ohio, Wisconsin; Air Plan Disapproval; Region 5 Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 87 Fed. Reg. 9838, 9868 (February 22, 2022) ("Proposed Rule").
[18] Proposed Rule at 9867.
[19] *Id.* at 9868.
[20] *See* SIP Disapproval at 9357.
[21] *See id.* at 9339.
[22] *Id.* at 9357.
[23] *Id.* at 9344, n.49.
[24] https://www.epa.gov/csapr/good-neighbor-plan-2015-ozone-naaqs

downwind nonattainment or maintenance-only receptor is just 0.32 ppb.[25] Notably, this modeling assumed no installation of additional pollution controls in Minnesota. The only emissions reductions included from Good Neighbor obligations were an annual reduction of 139 tons NOx from emissions control optimization at EGUs.[26]

II. Grounds for Reconsideration of the SIP Disapproval

Reconsideration is justified under either CAA § 307(d)(7)(B)[27] or Administrative Procedure Act ("APA") § 553(e) (5 U.S.C. § 553(e)).[28] Under CAA § 307(d), reconsideration is *required* "[i]f the person raising an objection can demonstrate to the Administrator that it was impracticable to raise such objection within such time or if the grounds for such objection arose after the period for public comment (but within the time specified for judicial review) and if such objection is of central relevance to the outcome of the rule."[29] Courts have found that an objection was "impractical to raise" "when the final rule was not a logical outgrowth of the proposed rule." *Alon Refining Krotz Springs, Inc. v. EPA*, 936 F.3d 628, 648 (D.C. Cir. 2019) (*per curiam*). In other words, when interested parties would not have "anticipated that the change was possible, and thus reasonably should have filed their comments on the subject during the notice-and-comment period." *CSX Transp., Inc. v. Surface Transp. Bd.*, 584 F.3d 1076, 1080 (D.C. Cir. 2009) (internal quotations omitted). An objection is of central relevance to the outcome of the rule if it "provides substantial support for the argument that the regulation should be revised." *Chesapeake Climate Action Network v. EPA*, 952 F.3d 310, 322 (D.C. Cir. 2020). Under the APA, EPA has "broad discretion to reconsider" its SIP Disapproval "at any time" Under the APA. *Clean Air Council v. Pruitt*, 862 F.3d 1, 8-9 (D.C. Cir. 2017).[30]

Three grounds support reconsideration under either standard. First, EPA's 2016v3 modeling did not have the benefit of Petitioners' or other public comments. As a result, it contains a significant overestimation of 2023 emissions for Minnesota. Second, EPA's 2016v3 modeling of the sole monitor supporting a potential linkage between Minnesota and Illinois is subject to significant bias which, if corrected for, results in the same receptor modeling attainment in 2023. Third, EPA's rejection of prong 2 of Minnesota's SIP was procedurally

[25] *See* Federal "Good Neighbor Plan" for the 2016 Ozone National Ambient Air Quality Standards, https://www.epa.gov/system/files/documents/2023-03/FRL%208670-02-OAR_Good%20Neighbor_Final_20230314_Signature_ADMIN%20%281%29.pdf, at 198 (pre-publication version).
[26] Compare *Id.* at 290, Table V.C.1-1; 291, Table V.C.1-2; and 452, Table VI.B.4.c-1.
[27] 42 U.S.C. § 76076(d)(7)(B).
[28] SIP disapprovals are not automatically subject to the exhaustion requirements of Clean Air Act § 307(d). 42 U.S.C. § 7607(d). This subsection lists 22 categories of agency action subject to the exhaustion requirement. SIP approval and disapproval, separate from issuance of a FIP, as occurred in the SIP Disapproval, is not addressed by any of these 22 categories.
[29] 42 U.S.C. § 7607(d)(7)(B).
[30] *See also Trujillo v. Gen. Elec. Co.*, 621 F.2d 1084, 1086 (10th Cir. 1980) ("Administrative agencies have an inherent authority to reconsider their own decisions, since the power to decide in the first instance carries with it the power to reconsider."); *United Gas Improvement Co. v. Callery Properties, Inc.*, 382 U.S. 223, 229 (1965) ("An agency, like a court, can undo what is wrongfully done by virtue of its order.")

improper because it was based entirely on results EPA obtained in 2023, well past the statutory deadline for Minnesota's SIP submission and EPA's decision approving or disapproving it.

A. Errors in EPA's New Emissions Data and Modeling, Which Were Not Subject to Notice and Comment, Support Reconsideration to Ensure EPA's Decision on Minnesota's SIP is Based on Valid and Accurate Information.

EPA "made a number of updates to [its] inventories and model design to construct a 2016v3 emissions platform which was used to update [EPA's] air quality modeling." SIP Disapproval at 9339. The SIP Disapproval uses "this updated modeling to inform [EPA's] final action on [state] SIP submissions," including Minnesota's. *Id.*

The new emissions inventory and modeling platform are of central relevance to EPA's rule. EPA identifies the 2016v3 platform as designed "to inform [the agency's] final action on these SIP submissions." SIP Disapproval at 9339. For Minnesota, the 2016v3 modeling results are the sole record citation EPA provides for its finding that prong 2 of Minnesota's SIP was "ultimately inadequate." *Id.* at 9357.

While there have been errors in each of EPA's inventories at each stage of the regulatory process, these new errors in the emissions inventory arose only with the publication of the final SIP Disapproval. Under both the APA and the CAA, EPA's rulemaking process requires adequate public notice and an opportunity to comment on the evidence on which EPA intends to rely for its final rules.[31] EPA's emissions inventory and modeling design changes were not made publicly available until EPA published the SIP Disapproval and several supporting documents on the same day. As a result, the public, including Petitioners, did not have the opportunity to review EPA's data and correct errors before then.

In the limited time Petitioners have had to review the 2016v3 data, we have identified significant errors in EPA's estimate of NOx emissions for 2023. As an example, EPA added 2,822 tons of NOx for Northshore Mining Co. – Silver Bay power. These boilers have been idled since October 2019 and are expected to have zero emissions in 2023. EPA itself recognizes that zero emissions are expected at this facility in both its OTP Policy Analysis, Appendix A and in its Unit-Level Allocations and Underlying Data for the Final Rule (both available at https://www.epa.gov/csapr/good-neighbor-plan-2015-ozone-naaqs). Yet EPA made no adjustment to its 2016v3 data, resulting in a significant overestimate of 2023 emissions from Minnesota used by EPA to justify disapproval of the Minnesota SIP. If EPA defends including 2,822 tons of NOx emissions for Silver Bay Power in the baseline actual emissions used to model Minnesota's downwind impact in 2023, then Minnesota's state allowance budget should be

[31] *See Small Ref. Lead Phase-Down Task Force v. EPA*, 705 F.2d 506, 540 (D.C. Cir. 1983) (adding evidence on which EPA relies after the close of the comment period would be "highly improper"); *see also Sierra Club v. Costle*, 657 F.2d 298, 400 (D.C. Cir. 1981) ("If … documents of central importance upon which EPA intended to rely had been entered on the docket too late for any meaningful public comment prior to promulgation, then both the structure and spirit of section 307 would have been violated."); *see also Kennecott Corp. v. EPA*, 684 F.2d 1007, 1019 (D.C. Cir. 1982) (finding EPA had not provided adequate opportunity for public comment on economic modeling placed in the docket only one week before promulgation of its final regulations).

increased to reflect those emissions and Silver Bay Power should receive proportional allowance allocations for the 2023 CSAPR ozone season trading program and beyond. To do otherwise would be internally inconsistent, which is an indication of arbitrary rulemaking.

For Minnesota, EPA's most recent modeling identified a single impacted maintenance monitor in 2023, at which Minnesota's maximum impact was 0.85 ppb. EPA's latest modeling projects this same receptor will be in attainment by 2026 with no reductions from Minnesota other than already "on the books" rules and regulations.[32] In other words, EPA's 2026 modeling confirms Minnesota's 2018 SIP conclusion that "the limits and controls that Minnesota already has in place across the state are sufficient to make it reasonably certain that Minnesota will not significantly contribute to nonattainment or interfere with maintenance in any other state" and that "no further controls or emissions limits are required to fulfill [Minnesota's] responsibilities under the interstate transport provisions for the 2015 ozone NAAQS under prongs 1 and 2 of Section 110(a)(2)(D)(i)(I)."[33]

Given the above considerations, EPA should grant reconsideration to reassess Minnesota's 2018 SIP in light of its own modeling showing that no further emission reductions are needed for Minnesota to satisfy its prong 2 good neighbor obligations.

B. The Sole Monitor that Links Minnesota Models in Attainment for 2023 When Bias is Removed.

Minnesota's only link to a downwind state receptor is the Alsip/Village Garage monitor located in Cook County, Illinois (170310001). This monitor is located near the southern shore of Lake Michigan at a land-water interface with complex meteorology**.** This monitor is currently measuring attainment with the 2015 ozone NAAQS using the 2021 4th highest daily maximum value (68 ppb). However, EPA's air quality modeling predicts that this monitor is at risk of violating the ozone NAAQS and, therefore, designates it as a maintenance-only receptor. Upwind states that interfere with this monitor's maintenance of the ozone NAAQS are linked through prong 2**.** However, if a corrected model predicts the monitor's maximum 2023 design value will attain the 2015 ozone NAAQS, this monitor falls out of the analysis at Step 1 and, since no other monitor links to Minnesota, EPA will have no basis for disapproval of prong 2 of Minnesota's SIP.

In the attached analysis, Alpine Geophysics demonstrates that the Cook County monitor models attainment for the 2015 ozone NAAQS in 2023. Alpine Geophysics evaluated this Cook County monitor and concluded that its location at a land-water interface at the southern shore of Lake Michigan presents highly complex meteorological conditions and ozone photochemistry that complicate the air quality model's ability to replicate ozone concentrations reliably. Of note,

---

[32] *See* Air Quality Modeling Final Rule Technical Support Document, https://www.epa.gov/system/files/documents/2023-03/AQ%20Modeling%20Final%20Rule%20TSD.pdf at 17, Table 3-5 (showing Monitor 170310001 no longer listed as a monitor-only receptor in the 2026 base case).

[33] 2018 SIP at 13.

EPA's application of a 12 km grid resolution in such areas is contrary to EPA's own guidance.[34] Alpine Geophysics reviewed EPA's day-specific model performance for the estimation of ozone concentrations on days EPA used to calculate future year design values and found significant bias in the majority of modeled day values used to designate this monitor site as a maintenance-only receptor. When Alpine Geophysics adjusted for this bias by using daily concentration values within acceptable normalized bias boundaries (+/- 15%), the updated list of top ten days used to designate the Cook County monitor resulted in both its average and maximum design values to be calculated in attainment with the 2015 ozone NAAQS.

When one attaining monitor modeled as a maintenance-only receptor is the sole basis for a state's linkage, a refined level of analysis is particularly important when predicting future design values and significant contribution. When that monitor is in a highly complex land-water interface area, it is not surprising for refined analysis to show significant bias. In its FIP rulemaking, EPA looked at this impact, but evaluated only one of ten Cook County monitors.[35] In doing so, EPA evaluated the only monitor out of the ten where EPA's performance-based recalculation resulted in a higher design value. As a result, EPA's sensitivity analysis materially understates the significance of the bias impact on the Alsip/Village Garage monitor and this issue remains central to EPA's evaluation of Minnesota's 2018 SIP.

Petitioners also had no ability to evaluate the bias in EPA's 2016v3 modeling of the Alsip/Village Garage monitor prior to EPA's release of its model and supporting data. As a result, this information arose after the close of the public comment period and within the time for judicial review.

Since Petitioners have identified significant bias in the sole receptor on which EPA relies to find a link to Minnesota and reject Minnesota's 2018 SIP, reconsideration is appropriate to evaluate the new information and analysis provided. When reasonably adjusting for the bias in EPA's 2016v3 modeling of that receptor, EPA will be in a position to confirm that Minnesota accurately concluded in 2018 that there are no "potential nonattainment or maintenance receptors significantly impacted by ozone transport from Minnesota in 2023" and that "[t]herefore, Minnesota does not have a responsibility to identify or implement any further controls or emissions limits to reduce downwind ozone contribution."[36]

C. Minnesota's SIP Should Have Been Approved Based on the Data Available at the Statutory Deadlines for Submission or Review.

The Clean Air Act sets out a detailed process for EPA's review of SIPs in CAA § 110(k). 42 U.S.C. § 7410(k). For timely submitted plans that have been deemed complete, like Minnesota's,

---

[34] Modeling Guidance for Demonstrating Air Quality Goals for Ozone, $PM_{2.5}$ and Regional Haze, https://www.epa.gov/sites/default/files/2020-10/documents/o3-pm-rh-modeling_guidance-2018.pdf (Nov. 29, 2018).

[35] *See* Federal "Good Neighbor Plan for the 2015 Ozone National Ambient Air Quality Standards Response to Public Comments on Proposed Rule, https://www.epa.gov/system/files/documents/2023-03/Response%20To%20Comments%20Document%20Final%20Rule.pdf at 196.

[36] 2018 SIP at 9.

EPA has twelve months to act on a plan submission. 42 U.S.C. § 7410(k)(2). For a plan that meets the requirements of the Clean Air Act, "the Administrator shall approve such submittal as a whole." *Id.* at (k)(3). If a portion of the plan revision meets all the applicable requirements, EPA "may approve the plan revision in part and disapprove the plan revision in part" but "[t]he plan revision shall not be treated as meeting the requirements of [the Clean Air Act] until the Administrator approves the entire plan revision as complying with the applicable requirements of [the Clean Air Act]." *Id.* In other words, while EPA has discretion to partially approve a SIP submittal that does not meet all requirements of the Clean Air Act, if a submission meets all requirements of the Act, EPA does not have discretion. It must approve the SIP. *See also Utah Physicians for a Healthy Env't v. Kennecott Utah Copper, LLC*, 191 F. Supp. 3d 1287, 1290 (D. Utah 2016) ("If a SIP satisfies the applicable requirements, EPA must approve it.").

In 2018, Minnesota submitted a timely and approvable SIP. As EPA acknowledges in the SIP Disapproval, Minnesota "was not projected to be linked to any receptor in 2023 in the EPA's 2011-based modeling."[37] Petitioners retained Alpine Geophysics to reanalyze Minnesota's SIP submission considering the best evidence available both at the time of Minnesota's SIP submission and at the time of EPA's statutory obligation to approve or disapprove Minnesota's SIP. As detailed in the attached report, Alpine Geophysics' review confirms that Minnesota's SIP submission: (1) had no material errors; (2) relied on the best science (including emissions data and modeling) available at the time; (3) fully complied with the CAA's requirements and EPA's guidance; and (4) would have been approved had EPA not incorporated information unavailable during the statutory review period. As a result, pursuant to 42 U.S.C. § 7410(k)(2) and (k)(3), by April 1, 2020, EPA had a non-discretionary duty to approve Minnesota's SIP. While EPA missed its statutory deadline, this did not relieve EPA of its duty to approve Minnesota's SIP.

While EPA now finds that "in light of more recent air quality analysis," Minnesota is linked to a single maintenance monitor in Illinois, this is based on information that did not exist at the time of Minnesota's SIP submission nor when EPA had a statutory obligation to approve the SIP. This was also not EPA's first use of untimely information to assess Minnesota's SIP. In 2022, EPA proposed to disapprove Minnesota's SIP "[s]ince new modeling ha[d] been performed by EPA with updated emission data," that EPA proposed "to primarily rely on … to identify nonattainment and maintenance receptors in 2023." Proposed Rule at 9867. As EPA acknowledged at the time, this was "a different method for projecting emissions" than what had been available to Minnesota for it to develop its SIP submittal. *Id.* EPA's repeated changes in emissions inventory and modeling platform after the deadline for SIP submissions and after Minnesota's SIP was deemed complete by EPA effectively moved the goalpost for Minnesota's SIP, undercutting the State of Minnesota's ability to identify the requirements EPA would apply to determine an approvable SIP.

The impact was significant. Minnesota's modeled impact went from contributing "below 1 percent of the NAAQS to receptors in 2023" to contributing "greater than 1 percent of the standards to two maintenance-only receptors in Illinois"[38] in the 2022 proposed SIP Disapproval

[37] SIP Disapproval at 9357.
[38] *Id.* at 9867-68.

to now being linked to one maintenance-only receptor in the 2023 SIP Disapproval (assuming no further adjustment for bias or data inaccuracies)). Notably, even using EPA's new data and modeling, Minnesota would still have had no linkage to a downwind maintenance receptor if EPA had not also moved the maximum threshold it indicated it would consider acceptable from 1 ppb to 1% (0.70 ppb).[39] As the D.C. Circuit has held, it is arbitrary and capricious to give states a "constantly moving target," *New York v. EPA*, 964 F.3d 1214, 1224 (D.C. Cir. 2020), let alone two. The language and structure of the Clean Air Act clearly give Minnesota and Petitioners the right to address this new data in the first instance in a SIP amendment, and not in a challenge to a SIP disapproval, as EPA now requires.

Notably, if EPA had followed the CAA procedures, it could have appropriately considered the new information it has developed since 2020, including the 2016v3 modeling it has introduced with the 2023 SIP Disapproval. But EPA cannot rely on its almost three year delay to circumvent the process and procedural protections set forth in the Clean Air Act. Rather, EPA was required to act on the SIP Minnesota submitted. If, after approval, EPA finds that a timely, complete and approved SIP nonetheless is "substantially inadequate … to mitigate adequately the interstate pollutant transport" or otherwise comply with the requirements of the Clean Air Act, "the Administrator shall require the State to revise the plan as necessary to correct such inadequacies." *Id.* at (k)(5). EPA also cannot simply disapprove the state's plan pending a new state submission that incorporated EPA's newly developed information, as the SIP Disapproval effectively does. In the event EPA finds a SIP Call is justified, EPA must first "notify the State of the inadequacies, and may establish reasonable deadlines (not to exceed 18 months after the date of such notice) for the submission of such plan revisions." *Id.* Further, "[s]uch findings and notice shall be public." *Id.* These procedural protections are an important component of the cooperative federalism embodied in the Clean Air Act. As courts have held, "[t]he Clean Air Act is an experiment in federalism, and the EPA may not run roughshod over the procedural prerogatives that the Act has reserved to the states, especially when … the agency is overriding state policy. *Bethlehem Steel Corp. v. Gorsuch*, 742 F.2d 1028, 1036–37 (7th Cir. 1984).

Multiple commenters, including the Minnesota Pollution Control Agency, have raised similar concerns arising from EPA's initial proposal to use 2016v2 modeling to disapprove state SIPs.[40] EPA has attempted to respond to those comments in the RTC, but in doing so, has not addressed the fundamental issue that EPA cannot disapprove a SIP that is approvable based on the information existing at the time that submittals are due, or even at the time EPA's SIP review was statutorily due, and cannot circumvent Minnesota's right to address new data in a SIP amendment, before EPA uses it to disapprove an otherwise approvable SIP. 42 U.S.C. §§ 7410(k)(3) and (5).

---

[39] Minnesota did not rely on the 1 ppb threshold for its SIP submission, but as EPA acknowledged, "[t]he 2018 modeling indicated the state was not projected to contribute above one 1 percent of the NAAQS to a projected downwind nonattainment or maintenance receptor. Therefore, the state may not have considered analyzing the reasonableness and appropriateness of a 1 ppb threshold at Step 2 of the 4-step Step interstate transport framework per the August 2018 memorandum." Proposed Rule at 9867.

[40] *See* RTC at 42-59.

EPA asserts in the SIP Disapproval that its use of new modeling and data did not move the goal post for states because EPA "did not evaluate states' SIP submissions based solely on the 2016v2 emissions platform (or the 2016v3 platform…)" but rather "evaluated the SIP submissions based on the merits of the arguments put forward in each SIP submission." SIP Disapproval at 9366. For Minnesota, however, EPA cites no basis or analysis for its SIP Disapproval other than the 2016v3 modeling results. Having relied on no other information to disapprove Minnesota's SIP, EPA cannot simply assert it had an additional basis with no additional substantiation. As the D.C. Circuit has noted, EPA cannot support its decision on only a "Delphic explanation of [Minnesota's] purported failure to carry its burden of proof." *New York*, 964 F.3d at 1224.

EPA also maintains that data and modeling it developed for the Proposed Rule in 2022, and now additional data and modeling it developed for the SIP Disapproval in 2023, supports a finding that Minnesota's SIP submission is "ultimately inadequate." SIP Disapproval at 9357. But even if this were the case, it does not give EPA a right to disapprove Minnesota's 2018 SIP. For data arising after EPA's statutory deadline to approve Minnesota's SIP, EPA could no longer rely on its obligation to use the "best information available." SIP Disapproval at 9366. Interpreting the Clean Air Act otherwise would not do justice to the cooperative federalism framework Congress established in CAA § 110, and would deprive states of important procedural protections allowing them to control and direct in the first instance, the implementation of the NAAQS within their borders.

The SIP Disapproval misapplies the D.C. Circuit's reasoning in *Wisconsin*, 903 F.3d at 322, when it asserts the SIP submission deadline is "'procedural'" and that to limit EPA's decision to information available at the time of the SIP submission or EPA's statutory review deadline would elevate it above requirements "'central to the regulatory scheme.'" SIP Disapproval at 9366 (quoting *Wisconsin*, 903 F.3d at 322. Neither *Wisconsin*, nor the case on which it relies, *Sierra Club v. EPA*, 294 F.3d 155 (D.C. Cir. 2002), addressed the issue presented here. In *Wisconsin*, the court was responding to an argument that EPA should have selected 2011 as its analytic year even though that year had already passed. In *Sierra Club*, the court was responding to a contention that EPA's ability to extend a SIP submittal deadline should support its authority to extend attainment deadlines. Here, EPA argues for an exception that would swallow the rule. If EPA could simply withhold ruling on a SIP until the State's information had become stale, and then disapprove the SIP and issue a FIP based on the "best available information," the cooperative federalism structure of the NAAQS would be an empty shell.

This is also not a situation like that which arose in *EME Homer City Generation, L.P. v. EPA,* 795 F.3d 118 (D.C. Cir. 2015). There, EPA had approved state SIPs in reliance on the Clean Air Interstate Rule ("CAIR"), which was subsequently found to have "more than several fatal flaws" by the D.C. Circuit. *North Carolina v. EPA*, 531 F.3d 896, 901 (D.C.Cir.2008) (*per curiam*). In addressing whether this ruling allowed EPA to "correct" its earlier SIP approvals under 42 U.S.C. § 7410(k)(6), the D.C. Circuit found EPA could do so, but only due to the unique circumstances of that case. *EME Homer City Generation*, 795 F.3d at 135 n.12 ("Our conclusion on Subsection 7410(k)(6) is limited to the unusual circumstances here, in which a federal court says that EPA lacked statutory authority at the time to approve a SIP."). Notably, the D.C. Circuit

did not decide whether EPA could rely on Clean Air Act §110(k)(6) to disapprove an approved SIP "in any other circumstances," and stated that its holding in particular "should not be read to diminish the scope or force of Subsection 7410(k)(5), which provides that whenever 'the Administrator finds that the applicable implementation plan for any area is substantially inadequate ... the Administrator shall require the State to revise the plan as necessary to correct such inadequacies.'" *Id.* (quoting 42 U.S.C. § 7410(k)(5)).

While in *EME Homer,* EPA had already approved several state SIPs, and in this rulemaking EPA has not yet approved Minnesota's SIP, this is a distinction without a difference. Minnesota submitted its SIP on October 1, 2018. It was deemed complete April 1, 2019.[41] EPA's period for review therefore ended April 1, 2020. As described in the Proposed Rule, Minnesota's SIP submission complied with the Clean Air Act and EPA's guidance for developing an interstate transport SIP for the 2015 ozone NAAQS. 87 Fed. Reg. at 9848-49. As detailed in the attached report, Alpine Geophysics' review confirms that Minnesota timely submitted an approvable SIP. By April 1, 2020, EPA had a statutory duty to approve Minnesota's SIP.

EPA's reliance on its 2016v3 modeling platform (which was not available to the public or interested parties) to reject the conclusions Minnesota reached based on the information that was available to all parties at the time is clearly of central relevance. Had EPA acted by its statutory deadline, Minnesota would have an approved SIP today. Further, while Petitioners have previously commented on the approvability of Minnesota's SIP, the basis for EPA's partial SIP Disapproval for Minnesota, including its decision to rely on its newer 2016v3 modeling platform, was not made public until the final rule. These grounds therefore arose after the close of the public comment period but before the time for judicial review. Reconsideration is therefore appropriate to address this procedural anomaly for Minnesota.

On reconsideration EPA should approve Minnesota's 2018 SIP based on the information that was available to EPA for its statutory review. The agency may then reassess whether, based on the information available today, including the above data and bias corrections, Minnesota's SIP remains sufficient to comply with prong 2 of the state's Good Neighbor obligations. For the reasons explained herein, EPA should find that the 2018 SIP was and is adequate to comply with prong 2.

III. Grounds for Stay of the SIP Disapproval

EPA has authority to stay the SIP Disapproval both pending reconsideration and pending judicial review. First, if the SIP Disapproval is subject to CAA § 307(d), a stay pending reconsideration can be granted for three months. Second, EPA has authority under the APA to stay the SIP Disapproval pending judicial review.

[41] *See* https://www3.epa.gov/airquality/urbanair/sipstatus/reports/mn_infrabypoll.html

A. A Stay Under CAA § 307(d)(7) is Appropriate.

The Clean Air Act provides that, if EPA grants reconsideration of a rule, "[t]he effectiveness of the rule may be stayed during such reconsideration…by the Administrator or the court for a period not to exceed three months." 42 U.S.C. § 7607(d)(7)(B). If the SIP Disapproval is subject to CAA § 307(d), a stay pending reconsideration is justified here.

EPA issued a final rule based primarily on emissions data and modeling that it did not make publicly available before issuance of the final rule. Even upon publication, EPA's release of data was partial and inadequate to reconstruct the modeling that EPA used for its final determinations. Obtaining the data and checking its accuracy has taken several weeks. It would take many more weeks to rerun EPA's modeling to confirm that the results support reversal of EPA's disapproval of prong 2 of Minnesota's SIP. It will likely take a similar amount of time to evaluate the evidence of bias Petitioners are submitting to confirm that it too, supports approval of Minnesota's SIP.

A stay will also not unduly impact downwind states. Minnesota is not modeled to interfere with attainment for any downwind state. Under EPA's most recent modeling, Minnesota is linked only to a single maintenance-only receptor, the most recent monitored design value of the monitor at this location was in attainment, and EPA's modeling for 2026 shows the receptor will model attainment as well with only minimal reductions from Minnesota. As EPA has itself emphasized, the SIP Disapproval does not require any action from the states.[42]

While a stay of the effective date of the SIP Disapproval for Minnesota would also prevent EPA from applying its FIP to Minnesota at the start of the upcoming ozone trading season, which is scheduled to start May 1, 2023, this is not likely to be relevant. In a recent filing, EPA has stated that the FIP is not likely to be effective until "late June to early July."[43] If EPA timely takes action on this reconsideration, this is well within the time EPA would need to conduct reconsideration. Further, while EPA has interpreted the CAA to require it "to address good neighbor obligations as expeditiously as practicable and no later than the next attainment date," RTC at 445, granting a stay of Minnesota's SIP denial pending reconsideration will not interfere with that goal. Minnesota is modeled to impact only a single maintenance-only monitor. As the D.C. Circuit has recognized, this 'may be a valid reason" to postpone addressing emission reductions until even after the next attainment date. *North Carolina v. EPA*, 531 F.3d 896, 912 (D.C. Cir. 2008). A reasonable stay to address reconsideration falls well within EPA's discretion.

B. EPA Should Stay the Effective Date of the SIP Disapproval Pending Judicial Review.

EPA can consider a stay of the entire SIP Disapproval for all affected states. Under the APA, EPA may stay the effective date of the SIP Disapproval pending judicial review when "justice

[42] *See, e.g.*, 2015 Ozone NAAQS Interstate Transport SIP Disapproval – Response to Comments ("RTC") at 466.
[43] Respondents' Consolidated Response in Opposition to the Motions for Stay of the Final Rule, *Texas v. EPA*, Case No. 23-60069, Doc. 109, at 12 (5th Cir. Filed March 27, 2023).

so requires." 5 U.S.C. § 705. Several Petitioners are filing a petition for judicial review of EPA's partial disapproval of Minnesota's SIP contemporaneously with this petition for reconsideration and stay. Multiple other petitions have already been filed for judicial review, including petitions by Arkansas, Kentucky, Oklahoma, Texas, Utah, and Wyoming. More are likely. These cases are already spread across four circuits, and additional litigation may expand the number of courts further.

The effective date of the SIP Disapproval is March 15, 2023. This effective date is significant for both legal and practical reasons. Legally, it will force EPA to promulgate a FIP within two years (though in this case EPA has already finalized its FIP). 42 U.S.C. § 7410(c)(1). States will also be required to prepare SIP revisions if they are interested in addressing the errors in EPA's analysis. Further, the significant legal flaws in EPA's SIP Disapproval discussed above, coupled with the technical and legal concerns it raises, make it likely that judicial review will result in a remand if not vacatur of the current SIP Disapproval. As a result, to avoid the unnecessary expenditure of EPA resources on a FIP, state resources on SIP revisions, and the resources of the public and regulatory industries in addressing a FIP that is likely to not be required, justice requires that the SIP Disapproval be stayed pending judicial review.

Further, while EPA is not bound to apply the same four-factor analysis used by courts for granting a judicial stay pending review, these factors indicate support for EPA in granting a stay of the SIP Disapproval. Under this standard, the considerations for a stay are:

(1) whether the stay applicant has made a strong showing that he is likely to succeed on the merits;

(2) whether the applicant will be irreparably injured absent a stay;

(3) whether issuance of the stay will substantially injure the other parties interested in the proceeding; and

(4) where the public interest lies.

Nken v. Holder, 556 U.S. 418, 434, 129 S.Ct. 1749, 173 L.Ed.2d 550 (2009) (citation omitted). These "four considerations are factors to be balanced and not prerequisites to be met." *State of Ohio ex rel. Celebrezze v. Nuclear Regul. Comm'n*, 812 F.2d 288, 290 (6th Cir. 1987).

1. Petitioners Have Made a Strong Showing They Are Likely to Succeed on the Merits

There is no fixed probability of success the agency must find in applying these considerations. "Ordinarily the party seeking a stay must show a strong or substantial likelihood of success. However, at a minimum the movant must show 'serious questions going to the merits and irreparable harm which decidedly outweighs any potential harm to the defendant if a [stay] is issued.'" *Id. (quoting In re DeLorean Motor Company*, 755 F.2d 1223, 1229 (6th Cir.1985)).

As discussed above, the SIP Disapproval has substantive and procedural flaws, each of which individually, and more so when combined, demonstrate "a high probability of success on the merits." *Ohio ex rel. Celebrezze v. Nuclear Regul. Comm'n.*, 812 F.2d 288, 290 (6th Cir.1987). Substantively, EPA's partial SIP Disapproval for Minnesota was based on an incorrect set of emissions data and biased modeling results that, when adjusted, support Minnesota's original conclusion that the state is not linked to downwind nonattainment or interference with maintenance and, even if linked, does not need to impose additional emission reductions to satisfy its Good Neighbor obligations. Procedurally, EPA did not follow the process required by the Clean Air Act for reviewing and approving Minnesota's SIP. In doing so, EPA deprived the State and Petitioners of the ability to address EPA's concerns in a SIP Call process.

Other flaws in the SIP Disapproval also strongly support a showing of likely success on the merits in a judicial challenge. In particular, we call to the agency's attention: (a) EPA's impermissible reliance on new data to disapprove prong 2 of Minnesota's SIP without providing adequate notice and an opportunity for public comment; and (b) the SIP Disapproval's subversion of the well-established and vital cooperative federalism underlying the entire Clean Air Act and in particular, the NAAQS.

a. *EPA Cannot Base its SIP Disapproval on Information that was Not Subject to Adequate Notice and Public Comment*

Under both the Administrative Procedure Act ("APA") and the CAA, EPA's rulemaking process requires adequate public notice and an opportunity to comment. *Small Ref.*, 705 F.2d at 547. This includes providing the public with the evidence on which EPA intends to rely. *Id.* at 540. Adding evidence on which EPA relies after the close of the comment period is "highly improper." *Id.* at 540; *see also Sierra Club*, 657 F.2d at 400 ("If … documents of central importance upon which EPA intended to rely had been entered on the docket too late for any meaningful public comment prior to promulgation, then both the structure and spirit of section 307 would have been violated."). Even reconsideration cannot cure an inadequate opportunity for notice and comment. *U. S. Steel v. EPA*, 595 F.2d 207, 214 (5th Cir. 1979) ("Permitting the submission of views after the effective date is no substitute for the right of interested persons to make their views known to the agency in time to influence the rulemaking process in a meaningful way.") (Internal quotations omitted).

In the SIP Disapproval, EPA "made a number of updates to [it's] inventories and model design to construct a 2016v3 emissions platform which was used to update [EPA's] air quality modeling." SIP Disapproval at 9339. The SIP Disapproval used "this updated modeling to inform [EPA's] final action on [Minnesota's] SIP submissions." *Id.* The details of these emissions inventory and modeling design changes were first described to the public in the SIP Disapproval and associated documents made publicly available the same day.[44] Even then, EPA did not make public its 2026 modeling results, reserving these for finalization of the FIP several weeks later.

[44] Even then, the supporting data and modeling platform were not made electronically available and needed to be requested by the public, which added several more weeks to gain access.

This data and modeling were clearly of central importance to EPA's disapproval of prong 2 of Minnesota's SIP. In fact, they are the sole basis for EPA's disapproval. *See* SIP disapproval at 9357 (finding Minnesota's analysis "ultimately inadequate" in light of EPA's "more recent air quality analysis"); *see also id*. (disapproving prong 2 of Minnesota's SIP because "[i]n the 2016v3 modeling, Minnesota is projected to be linked above 1 percent of the NAAQS to one maintenance-only receptor"). As a result, EPA was required to provide the public advance notice of its new data and an opportunity for meaningful public comment.

EPA's publication of its revised emissions inventory and modeling the day of the SIP Disapproval did not satisfy this requirement. In *Kennecott Corp. v. EPA*, 684 F.2d 1007, 1019 (D.C. Cir. 1982), the D.C. Circuit found EPA had not provided adequate opportunity for public comment on economic modeling placed in the docket only one week before promulgation of its final regulations. Here, EPA did not make its new emissions data and modeling publicly available until the *day* it published its final SIP Disapproval.

It is not enough to say that Petitioners had the opportunity to comment on EPA's previous version of the emissions data and modeling, or that EPA's latest data simply "incorporates comments generated during the public comment period." SIP Disapproval at 9366. As the D.C. Circuit stated in *Chesapeake*, 952 F.3d at 320, it would be an "unreasonable burden on commenters not only to identify errors in a proposed rule but also to contemplate why every theoretical course of correction the agency might pursue would be inappropriate or incorrect." The new data and modeling on which EPA relies for the SIP Disapproval differs significantly from that which was in the public record. Based on EPA's own summary of the data, Minnesota's largest contribution to a downwind maintenance receptor changed from 0.97 ppb to 0.85 ppb based on EPA's changes. *Compare* Proposed Rule at 9868 *with* SIP Disapproval at 9354. Since EPA's own adopted significant contribution threshold in the SIP Disapproval is 0.7 ppb, a change of 0.12 ppb is clearly significant.[45]

Under both the CAA and the APA, EPA was required to provide notice and an opportunity for public comment on its 2016v3 data. There is no question that EPA provided no notice or opportunity for comment. As a result, there is a high likelihood that Petitioners would be likely to prevail on the merits of a judicial challenge. This strongly supports EPA issuing a stay of the effective date of the SIP Disapproval pending judicial review.

b. *EPA Undermined State Primacy by Disapproving Minnesota's SIP Despite its Adherence to the Requirements of the Clean Air Act.*

As EPA acknowledges, "[t]he CAA establishes a framework for state-Federal partnership to implement the NAAQS based on 'cooperative federalism.'" SIP Disapproval at 9367. Under this model, "the Federal Government establishes broad standards or goals, states are given the

[45] EPA's 2016v3 modeling did not just result in significant changes to EPA's assessment of Minnesota's potential impact on downwind states. Six states (Arizona, Iowa, Kansas, New Mexico, Tennessee, and Wyoming) had their status as linked states change entirely. *See* Air Quality Modeling Technical Support Document 2015 Ozone NAAQS SIP Disapproval Final Action, https://www.regulations.gov/document/EPA-HQ-OAR-2021-0663-0017 at 24.

opportunity to determine how they wish to achieve those goals, and if states choose not to or fail to adequately implement programs to achieve those goals, a Federal agency is empowered to directly regulate to achieve the necessary ends." *Id.* Thus, "states have the obligation and opportunity in the first instance to develop an implementation plan to achieve the NAAQS under CAA section 110" and "EPA will approve SIP submissions under CAA section 110 that fully satisfy the requirements of the CAA." *Id.* As the Supreme Court has held: "[e]ach State is given wide discretion in formulating its plan, and the Act provides that the Administrator 'shall approve' the proposed plan if it has been adopted after public notice and hearing and if it meets [the CAA's] criteria." *Union Elec. Co. v. EPA*, 427 U.S. 246, 250 (1976) (*quoting* 42 U.S.C. § 7410(a)(2)).

EPA departed from this framework when it proposed a SIP disapproval based, not on any inaccuracy in Minnesota's evaluation of the data, but on EPA's preference for a different modeling platform and emissions inventory. EPA does not have the authority to condition SIP approval on the state's adoption of EPA's preferred approach, or to supplant Minnesota' interpretation of how best to achieve the goals of the CAA, as long as Minnesota complies with the requirements of the CAA.

EPA's position is predicated on an incorrect summary of its role in the SIP review process and the relevant case law. First, EPA's role is not "secondary" only in that "it occurs second in time." RTC at 425 (internal quotations omitted). EPA relies on *EPA v. EME Homer City Generation*, LP, 572 U.S. 489 (2014) for this proposition, but the case does not support EPA's position. It must be remembered that *EME Homer* involved EPA's authority to promulgate a FIP after EPA had already disapproved SIPs.[46] As a result, the Court did not address EPA's statutory duty to approve a timely and complete SIP submission, which is the issue here. The Court's "interpretations of CAA section 110(a)(2)(D)(i)(I)" on which EPA relies must be read in this light. RTC at 426. The Court upheld interpretive choices EPA made when issuing a FIP. The Court did not say EPA could delay approval until new information became available that supported its disapproval of the SIP.

Second, EPA is wrong to imply that *EME Homer* undermines the long line of cases setting out EPA's secondary (in substance, not just in time) role in developing plans to implement the NAAQS. In fact, the Supreme Court continues to cite these cases for their interpretation of EPA's role. *See West Virginia v. EPA*, 213 L. Ed. 2d 896, 142 S. Ct. 2587, 2600 (2022) ("EPA … does not choose which sources must reduce their pollution and by how much to meet the ambient pollution target. Instead, Section 110 of the Act leaves that task in the first instance to the States, requiring each 'to submit to [EPA] a plan designed to implement and maintain such standards

[46] *See EME Homer*, 572 U.S. at 507 ("The gravamen of the State respondents' challenge ***is not that EPA's disapproval of any particular SIP was erroneous***. Rather, respondents urge that, notwithstanding these disapprovals, the Agency was obliged to grant an upwind State a second opportunity to promulgate adequate SIPs once EPA set the State's emission budget. ***This claim does not depend on the validity of the prior SIP disapprovals***. Even assuming the legitimacy of those disapprovals, the question remains whether EPA was required to do more than disapprove a SIP, as the State respondents urge, to trigger the Agency's statutory authority to issue a FIP.") (emphasis added).

within its boundaries.'") (*quoting Train v. Natural Resources Defense Council, Inc.*, 421 U.S. 60, 65 (1975)).

The SIP Disapproval and RTC makes clear that EPA's disapproval of prong 2 of Minnesota's SIP was not based on a determination that Minnesota's SIP failed to meet the statutory requirements of CAA, but because EPA wanted to apply "a consistent set of policy judgments across all states for purposes of evaluating interstate transport obligations and the approvability of interstate transport SIP submissions for the 2015 ozone NAAQS under CAA section 110(a)(2)(D)(i)(I)." SIP Disapproval at 9339; *see also id.* at 9340 ("Effective policy solutions to the problem of interstate ozone transport going back to the NOx SIP Call have necessitated the application of a uniform framework of policy judgments to ensure an 'efficient and equitable' approach.") (quoting *EME Homer*, 572 U.S. at 519); RTC at 425-426. This was error. EPA's assessment of a SIP is to be based on whether the SIP compiles with the requirements of the CAA, not on EPA's policy preferences or desire for efficiency. Only after a state fails to comply with its statutory requirements can EPA impose what it believes best to achieve the substantive objective of the Act.

Because EPA's SIP Disapproval is based on improper factors that undermine the core cooperative federalism embodied in CAA § 110, Petitioners are likely to prevail on the merits of a judicial challenge. This further supports EPA issuing a stay of the effective date of the SIP Disapproval pending judicial review.

2. Petitioners Will Suffer Irreparable Harm from a Denial of Stay.

Relevant factors for evaluating the harm which will occur include: (1) the substantiality of the injury alleged; (2) the likelihood of its occurrence; and (3) the adequacy of the proof provided. In evaluating the harm which will occur both if the stay is issued and if it is not, the court must look to three factors: the substantiality of the injury alleged, the likelihood of its occurrence, and the adequacy of the proof provided. *Ohio ex re. Celebrezze*, 812 F.2d at 290 (*citing Cuomo v. United States Nuclear Regulatory Commission*, 772 F.2d 972, 974 (D.C.Cir.1985)).

The SIP Disapproval poses substantial and imminent injuries to Petitioners. As discussed in Section II above, the data which EPA should have used to evaluate Minnesota's SIP (see Section II.C), the best available data today, when flaws are addressed (see Sections II.A and B), and even the most likely future data (see Section II.D) strongly support a finding that Minnesota is not significantly contributing to nonattainment or interfering with maintenance of the 2015 ozone NAAQS in any state. EPA's SIP denial is predicated on the erroneous conclusion that there *is* interference with maintenance. This places the entire State of Minnesota in an erroneous state of non-compliance with the Good Neighbor requirement of the Clean Air Act.

EPA's SIP Disapproval also forces EPA to promulgate emission reductions through a FIP. 42 U.S.C. § 7410(c). EPA has already finalized just such a rulemaking. This leaves no time for reconsideration or judicial review to run its course before Petitioners are injured by the FIP, let alone time for Minnesota to remedy EPA's issues with the submitted SIP. Petitioners submitted detailed comments on the FIP identifying numerous substantial injuries from EPA's promulgation

of its Proposed FIP that are likely to occur, and supported by substantial evidence, including detailed technical reports.[47] While EPA made substantial modification to the FIP in response to comments, which Petitioners appreciate reflects considerable work on the Agency's part following the public comment period and has addressed many significant issues with the proposed FIP, the final FIP nonetheless includes significant obligations for Petitioners' electric generating units ("EGUs"), starting in the current 2023 ozone trading season (which begins this year). Even Petitioners without EGUs are substantial consumers of electricity, meaning that they will likely bear much of the burden of the higher costs needlessly imposed on Minnesota power producers because of the FIP. Further, while the Proposed FIP is a separate rulemaking, EPA has itself identified the SIP Disapproval as both a necessary step in issuance of a final FIP[48] and the stay of a SIP disapproval that is the basis for a FIP is an appropriate remedy for injuries arising from the FIP itself. *See EME Homer City Generation, L.P. v. EPA*, 696 F.3d 7, 44 n.6 (D.C. Cir. 2012) (Rogers, J., dissenting), *rev'd on other grounds,* 572 U.S. 489 (2014) ("If [states] wish to avoid enforcement of the Transport Rule FIPs because they contend EPA's SIP disapprovals were in error, the proper course is to seek a stay of EPA's disapprovals in their pending cases; if granted, a stay would eliminate the basis upon which EPA may impose FIPs on those States.") (citing 42 U.S.C. § 7410(c)(1)(B)).

3. Staying the SIP Disapproval will not Significantly Injure Other Parties.

As discussed in Section III.A above, the SIP Disapproval does not on its own impose any emission reductions on sources. As a result, a stay will not directly harm any other party. While a stay would also potentially delay the effective date of the FIP, this is unlikely to result in significant injury to other parties. EPA has recently extended a judicially-enforceable deadline to review Good Neighbor SIPs for three states to December 15, 2023 without any mention of public harm from the delay.[49] Even as a stepping stone to a FIP, while a stay will alleviate imminent and irreparable costs, it will not significantly impact NOx emissions. As discussed above, the FIP is unlikely to be effective until after the start of the current ozone trading season, resulting in an attenuated impact on 2023 emissions. Further, even if projected emission reductions for the full 2023 ozone trading season could be achieved, EPA projects total emission reductions from Minnesota of only 139 tons in 2023. This is unlikely to result in any significant impact on the Cook County maintenance monitor.

4. The Public Interest Lies in Granting a Stay.

As courts have held, there is a public interest enjoining inequitable conduct and in minimizing unnecessary costs to be met from public coffers. *See, e.g. B & D Land & Livestock Co. v. Conner*, 534 F. Supp. 2d 891, 910 (N.D. Iowa 2008). Here, the public interest supports a stay.

Steel, EPA-HQ-OAR-2021-0668-0798 (June 27, 2022); Comments of Xcel Energy, EPA-HQ-OAR-2021-0668-0411 (June 23, 2022); Comments of Minnesota Power, EPA-HQ-OAR-2021-0668-0539 (June 23, 2022); Comments of SMMPA, EPA-HQ-OAR-2021-0668-0351 (June 22, 2022); Comments of Cleveland-Cliffs Inc., EPA-HQ-OAR-2021-0668-0405 (June 23, 2022)

[48] 88 Fed. Reg. 9336 at 9362.

[49] *See* Joint Notice of Second Stipulated Extension of Consent Decree Deadlines, Doc. 33, *Downwinders at Risk v. Regan*, Case No. 4:21-cv-3551-DMR (N.D. Cal. Jan. 30, 2023).

As discussed in Section II.A above, EPA's SIP Disapproval was promulgated through the inequitable exclusion of public participation into the data central to EPA's final rulemaking. The result will be costly public expenditures, both by EPA to promulgate an unnecessary FIP and States to either prepare to implement EPA's FIP or prepare revised SIPs, and well as unnecessary costs borne by Petitioners.

While it was an error for EPA to disapprove Minnesota's SIP based on information not in the record at the time of submission, EPA can ameliorate the harm of this error by staying the effect of its SIP disapproval until the merits of the issues above can be fully evaluated and addressed.

IV. Conclusion

The State of Minnesota has expended substantial effort and resources to regulate the emission of NOx within its borders. Those efforts have successfully reduced State impacts on downwind receptors to a point that Minnesota is not a significant contributor to nonattainment or interference with maintenance of the 2015 ozone standard in any state. Based on the best available data and modeling science available at the time, Minnesota assessed its impact on downwind states, as it was required to do under the Clean Air Act, and appropriately concluded that it was not interfering with maintenance of attainment in any state. EPA has identified no error or omission in Minnesota's analysis. Nonetheless, based on data that was not available at the time, and in fact was not available to the public until February 2023, EPA partially disapproved Minnesota's Good Neighbor plan for the sole reason that, based on EPA's own modeling, it found a single maintenance receptor in Cook County, Illinois that Minnesota state emissions were impacting at a maximum level of 0.85 ppb. Neither Minnesota, nor Petitioners, were given an opportunity to comment on EPA's modeling, fully evaluate it, or even see it, until EPA published its final SIP Disapproval. While a complete analysis of EPA's modeling would require months, based on Petitioners' review of the data specific to them, and based on expert evaluations by Alpine Geophysics of the modeling and data EPA has provided, EPA's results likely overstate the impact Minnesota is having on the Cook County monitor. Because Petitioners have provided new information that reveals flaws in EPA's emissions inventory for Minnesota and bias in EPA's modeling of the lone monitor that links Minnesota emissions to a downwind state, Petitioners have raised material new data undermining the central basis for EPA's disapproval of prong 2 of Minnesota's SIP. Petitioners therefore request that EPA grant reconsideration of its partial SIP disapproval for Minnesota and approve Minnesota's 2018 SIP. Further, to avoid the significant and irreparable harm to Petitions arising from EPA's erroneous disapproval of prong 2 of Minnesota's SIP, EPA should stay the effectiveness of its SIP Disapproval as applied to prong 2 of Minnesota's SIP pending reconsideration and pending judicial review.

DOCUMENT OBJECTIVE

The objective of this document is for Alpine Geophysics, LLC to provide technical review and professional opinion of Minnesota Pollution Control Agency's (MPCA) SIP revision to address Clean Air Act (CAA) Section 110(a)(2)(D)(i)(I) and the Environmental Protection Agency's (EPA) final action to disapprove the Minnesota State Implementation Plan (SIP) published on February 13, 2023 in the Federal Register.

This document is formatted into three sections that discuss our review and assessment of the following issues:

A. Whether, given time to reassess, MPCA could demonstrate no linkage and/or no significant impact on attainment and maintenance in downwind states;
B. Whether U.S. EPA's revisions to its modeling approach since MPCA's SIP submittal were ancillary; and
C. Whether the Minnesota Pollution Control Agency's state implementation plan revision was approvable based on the state of the science at the time it was submitted to U.S. EPA.

At the end of this document, we also provide a summary of conclusions (Section D) and a regulatory and legislative timeline of actions taken on Minnesota's 2015 ozone SIP for reference (Section E).

A. Given time to reassess, MPCA could demonstrate no linkage and/or no significant impact on attainment and maintenance in downwind states.

EPA provided little time for MPCA to review the significant amount of technical information and associated calculations that were used to justify their disapproval of the Minnesota SIP, especially since EPA used a distinct and largely unrelated modeling platform, emissions inventory, and air quality model to justify its action instead of assessing the platform submitted by MPCA in support of its SIP. Notwithstanding the fact that four years and four months passed since the original Minnesota SIP was submitted to EPA, had appropriate time been given to MPCA to review and address EPA's final disapproval, MPCA could have addressed significant flaws in EPA's modeling that EPA itself should have addressed prior to finalizing any SIP disapproval.

It is our opinion that the U.S. EPA should have approved the MPCA's SIP when it was submitted in 2018. However, since EPA has put forward new modeling, we have reviewed this modeling and found several issues with the emissions that EPA used in the new modeling that weigh against using it as a basis for disapproving the Minnesota SIP.

1. EPA inappropriately revised the emission inventory and conducted new air quality modeling for SIP disapprovals without allowing a meaningful opportunity for stakeholder review and comment.

EPA's revisions to the emission inventory used in the modeling it previously has conducted for historic transport rules raises an administrative concern about public review and comment.

EPA notes in the proposed SIP disapprovals that, after the modeling it conducted in support of earlier transport rules, e.g., CAIR, CSAPR, CSAPR Update, CSAPR Closeout, and Revised CSAPR Update, the agency revised the emission inventory used in the modeling to assess the efficacy of prior transport rules. EPA conducted new modeling using this revised inventory and 2016v2 modeling platform. The agency describes the process as follows:

> *Following the Revised CSAPR Update final rule, the EPA made further updates to the 2016 emissions platform to include mobile emissions from the EPA's Motor Vehicle Emission Simulator MOVES3 model and updated emissions projections for electric generating units (EGUs) that reflect the emissions reductions from the Revised CSAPR Update, recent information on plant closures, and other sector trends. The construct of*

the updated emissions platform, 2016v2, is described in the emissions modeling technical support document (TSD) for this proposed rule.[1]

In December 2021, and in response to EPA requests for inventory review and updates[2,3,4], MPCA and other stakeholders submitted detailed comments on the 2016v2 emission inventory platform to correct errors that existed in that platform. EPA's declared efforts to revise this emission inventory platform at this time raised the question about whether EPA intended to update the modeling that has been used as the basis for the SIP disapprovals and the proposed FIP – but only in support of the final rule. EPA's own summary[5] of the comment process includes the statement that "by spring of 2021 it was necessary to make updates to the inventories to perform credible / defensible modeling in CY2021". In this summary, numerous and significant emission, control, and projection factor changes were requested and only with release of the final SIP denials were the changes shared by EPA for review.

As part of these comments, MPCA submitted comments on the 2016v2 emissions modeling platform (EMP) relative to three areas of improvement within Minnesota:

1. Non-electricity generation stationary (non-EGU) point source emissions controls
2. Future year emissions projections for various point and non-point inventory sectors
3. Stationary point EGU growth rate differences between the ERTAC vs IPM models

Non-EGU point source emissions controls

LADCO worked with member states to identify the highest-emitting sources and applicable control technology information for non-EGU stationary point sources in the region. They generated a spreadsheet with the highest-emitting non-EGU sources in 2016 for each LADCO state, including Minnesota, which also included state updates on emissions control information for listed sources.

A provided spreadsheet identified control information and future emission rate changes for several Minnesota sources within the 2016v2 EMP. The control information identified accounts for the installation of low NOx burners at the taconite facilities in Minnesota as part of the Regional Haze Taconite FIP. Based on MPCA estimates, just under 11,000 tpy in NOx reductions were expected due to the controls required by the Taconite FIP. MPCA noted the importance of

[4] https://www.epa.gov/air-emissions-modeling/2016v2-platform
[5] https://gaftp.epa.gov/Air/emismod/2016/v2/reports/comments/Summary_of_2016v2_comments_by_sector_01312022.pdf

having these significant reductions included in the EPA EMP for non-EGUs and requested that EPA do so.

Below is a summary of approximate NOx emission changes for these sources.

- 2,100 tpy at Minorca Mine
- 2,300 tpy at Hibbing Taconite
- 700 tpy at United Taconite
- 3,600 tpy at US Steel Keetac
- 2,100 tpy at US Steel Minntac

Future year emissions projections for various point and non-point inventory sectors

LADCO used US EPA-generated emissions projection reports and identified a list of SCCs that they believed had incorrect future year projection rates. The 2016v2 EMP projection rates were not found consistent either with real-world emissions trends or regional emissions projection information. It was requested that EPA replace the 2016v2 EMP projections for these sources with the updated rates provided by LADCO.

A spreadsheet was provided that included the list of the SCCs with alternative projection information and LADCO comments on the sources of the alternative information.

Stationary point EGU growth rate differences between the ERTAC vs IPM models

LADCO recognized that EPA used the Integrated Planning Model (IPM) to estimate future year EGU emissions, and that the IPM projection methodology differed from the Eastern Research Technical Advisory Committee (ERTAC) EGU model that is endorsed by the MJOs and most of the states in the eastern half of the country. Minnesota noted support for the use of ERTAC EGU projections in the 2016v2 EMP and asked EPA to consider replacing IPM projections with ERTAC EGU projections for sources in the LADCO region in subsequent modeling platforms.

While most states urged EPA to rely on modeling that accurately reflects current on-the-books regulatory requirements and up-to-date emission inventories, they also strenuously object to the possibility that EPA would conduct any such additional modeling to support a final rule. Furthermore, these states object to EPA not providing the opportunity for those data to be reviewed, analyzed, commented upon, and having those comments addressed by EPA in advance of any final decision on the subject SIP disapproval (or for that matter the related FIP). These concerns were also expressed in July 2021 by several MJOs (WESTAR, LADCO, SESARM, MARAMA, and CENSARA).[6]

---

EPA's Previously Unreleased 2016v3 Modeling Platform

EPA's newest emissions inventory and modeling platform are of central relevance to EPA's final rule. The SIP Disapproval itself identifies EPA's "updates to the 2016v2 inventories and model design to construct a 2016v3 emissions platform which was used to update the air quality modeling" and used "this updated modeling to inform its final action on these SIP submissions.[7]" These data and modeling in fact form the basis for EPA's final disapproval of Minnesota's SIP[8] (finding Minnesota's analysis "ultimately inadequate" in light of EPA's "more recent air quality analysis"). This issue also arose only with the publication of the final SIP Disapproval. EPA's publication of its revised emissions inventory and modeling did not occur until then, and states had no access to the data, the modeling, or even the results of EPA's modeling until that time.

In the limited time that states have had with the modeling data, significant errors have been identified. A robust public comment process for these data is necessary to correct all significant errors to ensure that EPA's regulatory decisions are based on valid and accurate information. Within Minnesota alone, some of these errors include the following:

- EPA incorrectly included NOx emissions of 2,822 tons in 2023 for Northshore Mining Co. – Silver Bay in the future year air quality modeling and associated significant contribution calculations but not in the engineering analysis used to calculate state level EGU budgets. The subject boilers have been idled since October 2019 and are expected to have zero emissions in 2023;

- EPA predicts zero emissions at Minnesota Power's Laskin Energy Center units that have been converted to natural gas and expect continued MISO dispatch to support the renewables transition and regional grid needs / constraints;

These errors, and many like these presumed in other states in the modeling platform, may significantly impact the results of EPA's analysis and could be the difference in nonattainment and maintenance determinations or whether Minnesota is having a downwind effect on the lone Illinois maintenance monitor that subjects Minnesota to the Good Neighbor provisions of the Clean Air Act.

It is our opinion that the absence of inclusion of Minnesota's and other stakeholder's valid EMP revision submissions, as requested by EPA, and without a rerun of the air quality model in both the base and projection year simulations, EPA cannot appropriately identify monitors as nonattainment or maintenance, and in turn, cannot calculate upwind state significant contribution metrics from these same data. Non-EGU emission controls and their associated NOx emission reductions as documented and submitted by MPCA, could be enough to change

---

[7] 88 FR 9339
[8] 88 FR 9357

nonattainment designations and linked significance using an updated platform, and needs to be considered before making any final decision on denial of MPCA's SIP.

2. The Cook County, Illinois monitor to which Minnesota is linked, is located at the interface of land and water along Lake Michigan and is not properly characterized by EPA's supporting modeling.

EPA did not make a bias adjustment for the only receptor that EPA found "links" Minnesota to downwind interference with maintenance. Observed values at this location (the Alsip/Village Garage monitor) demonstrate significant model overprediction, justifying the need for adjustments to address bias. While EPA has recently investigated bias in southern Lake Michigan, this assessment selectively analyzed only one monitor, which was not representative of the bias observed at the Village Garage monitor. The failue to adequately address bias in EPA's modeling resulted in an overprediction of ozone. Adjusting for this bias supports the conclusion that the Alsip monitor models in attainment of the 2015 ozone NAAQS and therefore Minnesota is not interfering with maintenance at this monitor. EPA's ozone attainment modeling guidance states that:

> *"[t]he most important factor to consider when establishing grid cell size is model response to emissions controls. Analysis of ambient data, sensitivity modeling, and past modeling results can be used to evaluate the expected response to emissions controls at various horizontal resolutions for both ozone and PM2.5 and regional haze. If model response is expected to be different (and presumably more accurate) at higher resolution, then higher resolution modeling should be considered. If model response is expected to be similar at both high and low(er) resolution, then high resolution modeling may not be necessary. The use of grid resolution finer than 12 km would generally be more appropriate for areas with a combination of complex meteorology, strong gradients in emissions sources, and/or land-water interfaces in or near the nonattainment area(s)"*

EPA's modeling in support of the SIP disapprovals simulated a national domain using a 12km grid resolution domain wide. While this makes running a national, regional simulation easier from a technical perspective, it neglects the important issue of the complex meteorology and/or land-water interfaces in or near the nonattainment or maintenance monitors of interest. Indeed, EPA's choice of a 12km grid is an arbitrary choice in contravention of its own guidance when modeling Illinois monitors in Cook County because these monitors are at land-water interfaces.

Photochemical modeling along coastlines is complex for two reasons. First, the temperature gradients along land/water interfaces can lead to localized on-shore/off-shore flows; and

ALPINE GEOPHYSICS

secondly, the photochemical model formulation spreads the emissions in a grid cell throughout the full grid volume of the cell.

Figure 1 presents a unique area along Lake Michigan that is challenged by these complex meteorologic issues at land-water interfaces. For the Cook County, Illinois monitor with which Minnesota is linked in this final rule, EPA's published model performance evaluation (MPE) metrics for ozone have been reviewed by Alpine on a day-specific basis.

Figure 1. Lake Michigan shoreline monitors located on land/water interface in Illinois.

Studies indicate that air quality forecast models typically predict large summertime ozone abundances over water relative to land and that meteorology around Lake Michigan is distinctly unique; both shortcomings warrant individualized attention and a finer grid resolution to best explore actual conditions.[9,10,11]

The 3x3 neighborhood of grid cells used in determining the design values of the relative response factor (RRF) at land-water interface monitors extends into the noted water bodies. Under current guidance, the top ten modeled days within this 3x3 matrix are used in determining this RRF for each monitor with any cell identified as 50 percent or more water, except for cells including monitors, which are omitted from the calculations.

Table 1 below provides a list of top 10 days at monitor 170310001 (Alsip/Village Garage), the Cook County monitor in Illinois to which Minnesota is linked, and comparisons of daily modeled

maximum daily average 8-hour ozone concentrations (highlighted in green) and observations on the same date in 2016 (highlighted in blue). These are the dates selected in EPA's modeling to represent the highest modeled days used in estimating future year design values.

As can be seen in Table 1 below, several days selected for RRF calculation have modeled ozone concentrations that fall outside of normally acceptable normalized bias (NBias) boundaries (±15%), here as the result of over (positive bias) predictions compared to observed concentrations on those days. In fact, at the monitor example below, seven of the ten selected days fall outside of the ±15% bias metric (highlighted in orange in the Table) with a maximum normalized bias of 93.60% (observation was 45.25 ppb and modeled concentration was 87.60 ppb; a difference of over 42 ppb).

When these dates are used, EPA's calculation of future year DV is 68.2 ppb (average) and 71.9 ppb (maximum) using the average RRF of 0.9349, identifying this as a maintenance monitor.

Table 2. Alternate bias adjusted list of top 10 days at the Alsip/Village Garage monitor (170310001) in Illinois used in RRF and resulting calculated design values (ppb).

As a result of this bias adjusted calculation, the Alsip / Village Garage monitor located in Cook County, Illinois (170310001) has an average RRF of 0.922, resulting in an average 2023 DV of 67.3 ppb and a maximum DV of 70.9 ppb, identifying this monitor as attainment of the 2015 ozone NAAQS.

Under Step 1 of the ozone transport framework established by EPA, this monitor would not be considered as part of the list of receptors in the significant contribution calculation and therefore any linkages from upwind state contributions would be irrelevant.

Since this is the only monitor in which Minnesota is linked as a significant contributor under EPA's modeling, this linkage would be broken, and Minnesota should be removed from the list of contributing states to downwind receptors.

In the Response to Comments document from the rule, EPA attempted to address the bias issue by preparing an analysis at select monitors in the modeling domain. Specifically, EPA notes[12] that,

> *"Even though the EPA disagrees with commenter's assertion to "throw out" specific days at individual monitors for which model performance does not meet the criteria, out of an abundance of caution, the EPA performed a sensitivity analysis for selected receptors in which the projected 2023 DVs and contributions were recalculated after removing individual days that fell outside the Emery et al., criteria for normalized mean bias and/or normalized mean error. The EPA chose receptors in Coastal Connecticut, the Lake Michigan area, Dallas, and Denver for this analysis. The specific receptors included in this sensitivity analysis are Stratford, Connecticut, Chicago/Evanston, Illinois, Dallas/Denton, Texas, and Denver/Rocky Flats, Colorado."* (emphasis added)

While we agree with EPA's technical approach and calculations in their Chicago/Evanston example provided, EPA's selection of the Evanston monitor is questionable as it is the only monitor out of ten in Cook County, Illinois (three which are identified as maintenance) where performance-based recalculation results in higher design values. This is also not the unique, individual monitor to which Minnesota is exclusively linked. Table 3 presents the ten Cook County, Illinois monitors in EPA's modeling results[13].

As presented in Table 2, using bias-adjusted design values for the individual receptor with which Minnesota is linked (170310001), this monitor is calculated to be in attainment of the 2015 ozone NAAQS in 2023. This decrease is also seen in the remaining Cook County monitors that EPA did not consider in its response to comments on the issue.

Table 3. Future year design values (ppb) and significant contribution calculations of upwind states to monitors in Cook County, Illinois.

Table 4 demonstrates that the Evanston monitor (170317002) in which EPA used to illustrate a noted increase in design value calculations using a bias adjustment calculation was the only monitor out of the ten where the average and maximum design values increased. Had EPA selected any other monitor from Cook County to demonstrate the bias adjustment, their conclusion may have been different than presented in the Response to Comment document.

Table 4. EPA final rule and bias-adjusted future year design values (ppb) of monitors in Cook County, Illinois.

Additionally, the LMOS 2017 study[14] shows that for Lake Michigan coastal monitors the air quality model even at a 4 km resolution does not simulate the proper timing and structure of the land/lake breeze or the inland penetration of elevated ozone concentrations. A review of this LMOS study[15] states "To reproduce the timing and magnitude of the ozone time series at coastal monitors, ozone production over the lake must be correctly simulated; furthermore, details of the lake breeze must be accurate——timing, horizontal extent, and vertical structure." Based on recommendations from the LMOS 2017 study research team, a horizontal resolution of at most 1.3 km is required to reasonably resolve the complex meteorology of the air/water interface for the great lakes and coastal ocean areas. The LMOS 2017 Study researchers believe that a 1.3 km grid spacing will assist in the resolution of the large ozone concentration gradients that often occur along the shoreline as well as the inland penetration of the lake breeze circulation.

As the Alsip / Village Garage example shows, days where modeled ozone was predicted at concentrations differing up to ± 42 ppb are being used to estimate future year ozone concentrations and to make determinations of nonattainment, maintenance, and significant contribution from upwind sources.

Furthermore, to adequately capture the inland penetration of the lake breeze, the LMOS report also cites the need for accurate Lake Michigan water temperatures and correct model physics options. EPA's use of the Pleim-Xiu Land Service Model (LSM) does not adequately capture the lake breeze inland penetration. A review of wind vector observations (from the Meteorological Assimilation Data Ingest System (MADIS) network) compared to modeled wind vectors on RRF and significantly contributing days at nonattainment monitors highlights the differences in wind direction and speed during many hours of these predicted high ozone episodes.

On many days with relatively simple meteorology, EPA-developed wind fields using the Weather Research and Forecasting (WRF) Model agree with the MADIS observed winds. However, the modeled winds have strong disagreement with the observed meteorology on June 15, July 7, July 27 and August 4, 2016, the four days when the CAMx model predicted the highest ozone concentrations and are thus used in estimating RRFs and future year ozone design values. The following presents an example on August 4, 2016, a day within the top ten highest model estimated MDA8 ozone concentrations at the Alsip / Village Garage monitor.

[15] Stanier, C. O., & et al. (2021, November). Overview of the Lake Michigan Ozone Study 2017. BAMS, 19.

In Figure 2 below, the black wind vectors are the wind fields used in the CAMx model. For clarity only every third grid cell is presented. The red vectors are the hourly observed wind vectors from the MADIS archive. The hourly results from 1300 CDT through 1600 CDT are presented in these Figures. The observations clearly show a broad persistent land to lake flow along the western shoreline while the model shows a persistent lake to land flow in this same region during this same period. For this timeframe, when the model is estimating the highest ozone for the ozone season at this receptor, the model has the winds flowing from the lake to the shore while the observations are winds flowing from the shore to the lake.

Figure 2 demonstrates that observed winds (red arrows) are seen moving from land to lake along the western shoreline of Lake Michigan, typically associated with clearing events and lower ozone levels in areas in and around Chicago. In contrast, the model (black arrows) shows a lake to land flow, typically associated with higher model predicted ozone concentrations due to the higher reactive photochemistry over water bodies.

ALPINE GEOPHYSICS

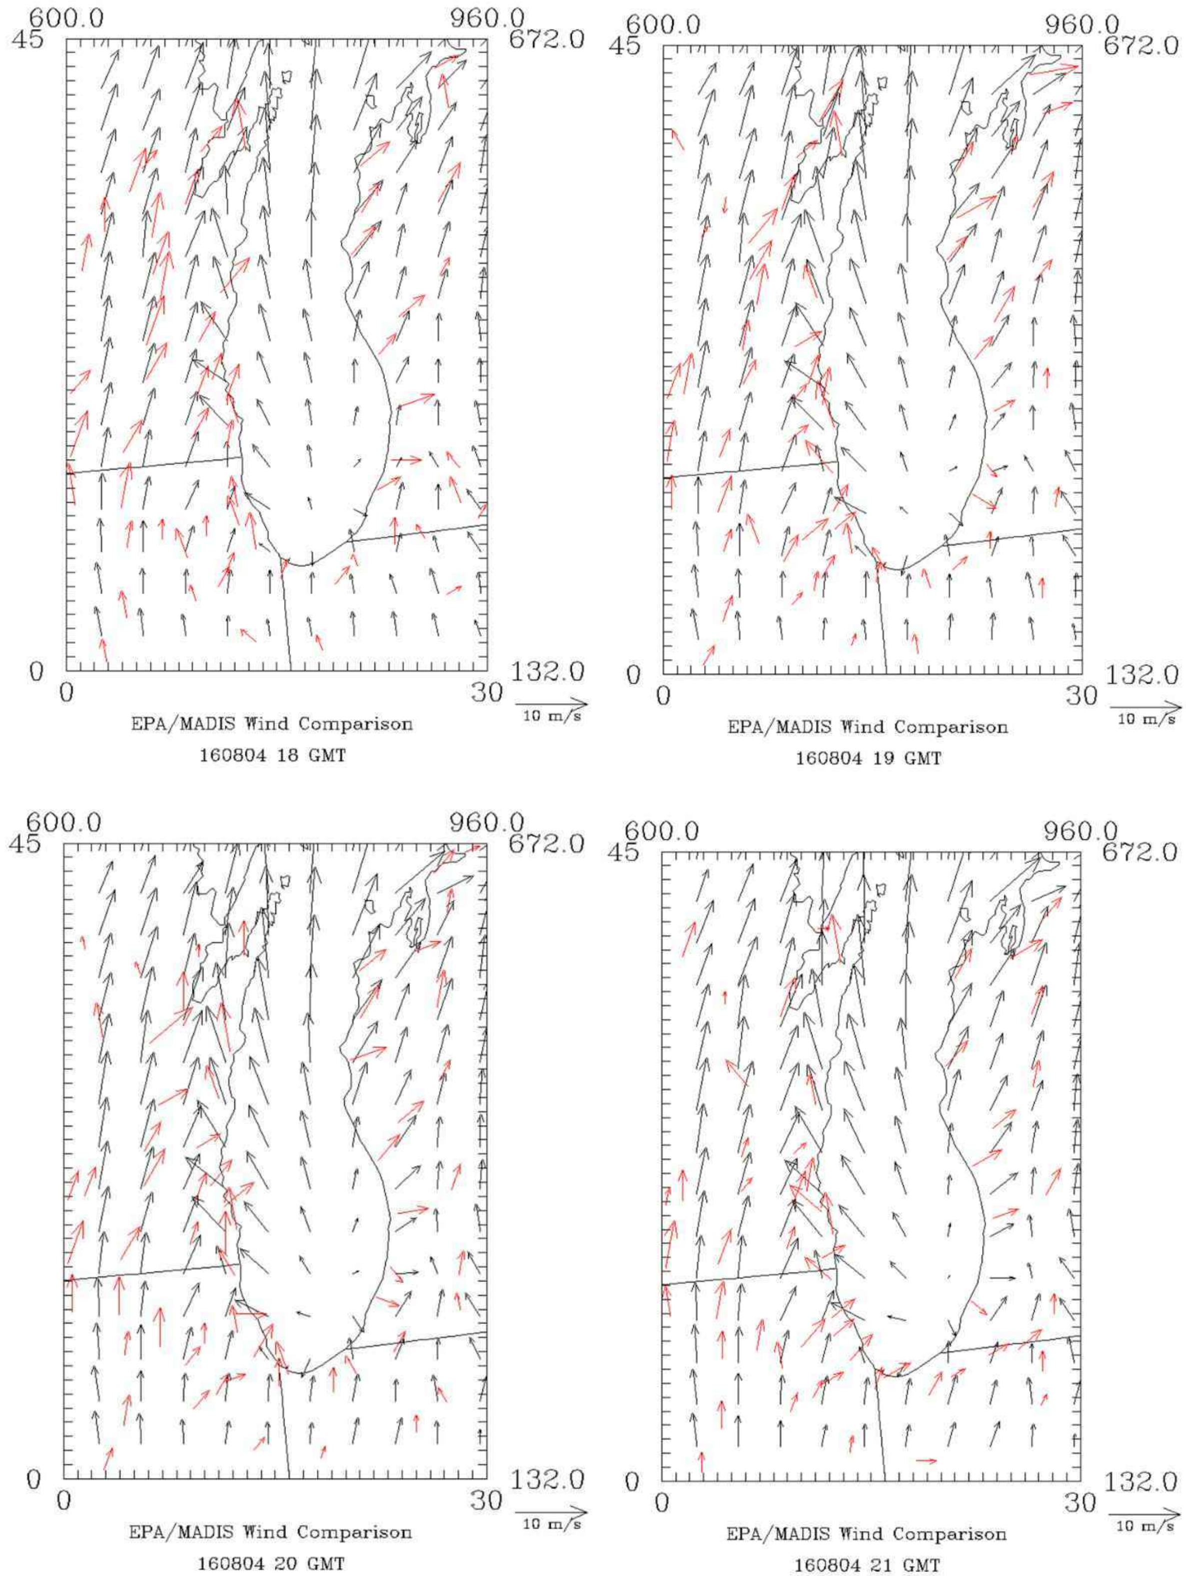

Figure 2. Model estimated (black) and observed (red) winds in the Lake Michigan area at 1300 CDT (top left), 1400 CDT (top right), 1500 CDT (bottom left), and 1600 CDT (bottom right) on August 4, 2016.

These large differences in observed and modeled wind directions are altering the concentration calculations as well as the source/receptor relationships (e.g., determining which sources are "upwind") of the Illinois monitors. As a result, the model cannot accurately reproduce the chemical processes involved with ozone formation. The erroneous modeled meteorological conditions fundamentally change the ozone formation chemistry and modeled source contributions as the chemical transport model predicts more emissions coming from the Chicago urban area than likely the case consistent with the observed wind fields.

When the model is having difficulty resolving fundamental flow patterns in this region with this grid size resolution, EPA needs to reconsider the merit of using the model with this configuration to determine nonattainment status in Step 1 as well as linked significant contributors at receptors in this region under Step 2. For these reasons, EPA must consider finer grid resolution modeling over the Lake Michigan domain to adequately capture ozone formation and significant contribution at receptors located on complex land-water interfaces because model evaluation shows that the model fails to adequately characterize ozone production at these monitors.

Absent a wholesale revision of EPA's modeling protocol, it is our opinion that EPA's use of modeling with poor performance at critical monitors amounts to an unreliable result when used to establish nonattainment or maintenance monitors under Step 1 or linkages under Step 2 of the 4-step framework. Should more refined modeling be undertaken to review the ozone formation potential at monitors located in these land-water interfaces, results may show that these monitors demonstrate modeled attainment and/or remove significant contribution linkages from upwind states.

3. EPA is obligated to address VOC emissions as a critical factor that is influencing ozone nonattainment/maintenance monitors in Illinois

EPA's modeling fails to account for VOC-limited conditions in the Lake Michigan region. Recent information supports the conclusion that VOC-limited conditions in the regional are much more significant that EPA has assumed. This results in EPA's analysis overemphasizing upwind NOx contributions from Minnesota on ozone values at the Alsip/Village Garage monitor and an underemphasis on local VOC contributions, which can be more effectively used to control ozone.

In addition to grid size resolution and complex meteorology issues, modeling performed by EPA[16] and the LMOS 2017 study both showed a negative bias in predicted ozone concentrations in the Lake Michigan region. LMOS 2017 study researchers have experimented with increasing

[16] EPA-HQ-OAR-2021-0668-0099

anthropogenic VOC emissions and decreasing anthropogenic NOx emissions. These emission changes improved air quality model performance reducing the negative bias. VOC speciation and spatio-temporal release patterns should also be reviewed. This evaluation by the LMOS 2017 research scientists indicates there are significant errors in the quantity and speciation of the VOC/NOx emissions used in the EPA's air quality modeling platform to characterize state contribution to ozone in Step 2 of EPA's analyses linking these states to critical nonattainment monitors.

Several downwind nonattainment monitors in urban areas around Lake Michigan recently have been shown to be largely unresponsive to ozone reduction strategies consisting of regional interstate NOx control and that high ozone days in the region were predominantly VOC-limited in nature. This was demonstrated in multiple ozone episodes extensively evaluated in the Lake Michigan Air Directors Consortium (LADCO) Lake Michigan Ozone Study (LMOS) 2017 study[17] where ozone precursor measurements indicated relative increases in VOC concentrations with increases in ozone and where biogenic VOC increases outpaced those of anthropogenic VOC.

In contrast to the peer reviewed research resulting from the 2017 LMOS data collection effort, EPA recently documented its support for additional NOx controls in stating that its "review of the portion of the ozone contribution attributable to anthropogenic NOX emissions versus VOC emissions from each linked upwind state leads the Agency to conclude that the vast majority of the downwind air quality areas addressed by the proposed rule under are primarily NOX-limited, rather than VOC-limited."[18] However, the current situation is that the modeling as conducted does not accurately characterize ozone levels on high ozone days, underpredicting by 10 + ppb, which is a huge error. Other studies indicate that, to better match actual conditions, the model needs less NOx and higher windspeeds at lower levels. The model is therefore demonstrating that less NOx means more ozone and higher ozone concentrations. That further means that, proportionally, the attribution of ozone to out of state NOx predicts a higher impact than is occurring.

The modeled VOC and NOx emission tracers in EPA's Anthropogenic Precursor Culpability Assessment (APCA) modeling can give a general indication of the VOC/NOx sensitivity, but EPA assigning definitive numerical values to that sensitivity provides inaccurate projections, especially using APCA that is known to have a bias toward attributing ozone to NOx emitting anthropogenic sources under VOC sensitive conditions. As documented in the CAMx v 7.10 User's Guide[19], "when ozone formation is due to biogenic VOC and anthropogenic NOx under

[17] https://www.ladco.org/wpcontent/
uploads/Research/LMOS2017/LMOS_LADCO_report_revision_apr2019_final.pdf
[18] 87 Fed. Reg. 20,076
[19] https://camx-wp.azurewebsites.net/Files/CAMxUsersGuide_v7.10.pdf, page 177.

VOC-limited conditions (a situation where OSAT would attribute ozone production to biogenic VOC), APCA attributes ozone production to the anthropogenic NOx present. Using APCA instead of OSAT results in more ozone formation attributed to anthropogenic NOx sources and less ozone formation attributed to biogenic VOC sources." Here, it is believed that as applied in this case (with biogenic emissions as an uncontrollable source group), EPA has overestimated the efficacy of NOx controls on these receptors as modeled results have a bias toward attributing more ozone formed to NOx emissions than VOC emissions.

Furthermore, an independent review of EPA's own NOx and VOC contributions challenges the Agency's statement that "[o]ur analysis of the ozone contribution from upwind states subject to regulation under this proposed rule demonstrates that the vast majority of the downwind air quality areas are NOX-limited, rather than VOC-limited."[20] This statement is based on all anthropogenic NOx and VOC emissions from all upwind states and is defined as having NOx emissions contribute to 80% or more of the ozone concentrations modeled at each receptor[21].

EPA further goes on to state that "[t]his review of the portion of the ozone contribution attributable to anthropogenic NOX emissions versus VOC emissions from each linked upwind state leads the Agency to conclude that the vast majority of the downwind air quality areas addressed by the proposed rule under are primarily NOX-limited, rather than VOC-limited."[22]

Alpine's review of EPA's modeled NOx and VOC contributions, by upwind state, focusing on the future year modeled days used in each receptor's Step 2 linkage calculation provides a slightly different picture for monitors around Lake Michigan. As demonstrated in Table 5, of the top future year modeled days impacting significant contribution calculations at the Cook County, Illinois monitor with which Minnesota is linked, more than half of the days are shown to have NOx emission contributions from Illinois below the 80% threshold noted by EPA in determining NOx-limited regions. This is an indicator that on those days, and from anthropogenic sources from those states, VOC controls may demonstrate meaningful impact on ozone concentration reductions at this receptor.

Researchers at the University of Maryland (UMD) have also found in a study of chemical transport model results that by 2023, model predictions of ozone formed under VOC-limited conditions are substantial near the Long Island Sound and the Great Lakes. In a recent presentation[23], they document a source apportionment simulation, conducted with CAMx/APCA on future-year 2023 to determine the major contributing sources and states to air

quality within non-attainment areas. Their findings indicate that ozone production under VOC-limited conditions is important at coastal locations near Long Island Sound and the Great Lakes.

Table 5. Modeled ozone contributions to Cook, Illinois monitor (170310001) by percent of emissions from anthropogenic NOx (O3N) compared to emissions from anthropogenic NOx and VOC (O3). Yellow cells indicate contributions of anthropogenic VOC emissions greater than EPA identified "NOx-limited" areas.

Figure 3 presents UMD's findings for model predictions of ozone formation under NOx limited conditions excluding the influence of boundary and initial conditions from the modeling input. As can be seen in these figures, regions around Lake Michigan demonstrate a significantly higher percentage of ozone formed by VOC (blue in color) compared to NOx than most of the eastern US. This observation is seen both on modeled days greater than 60 ppb and on the top ten days of the ozone season (days used in RRF and significant contribution calculations).

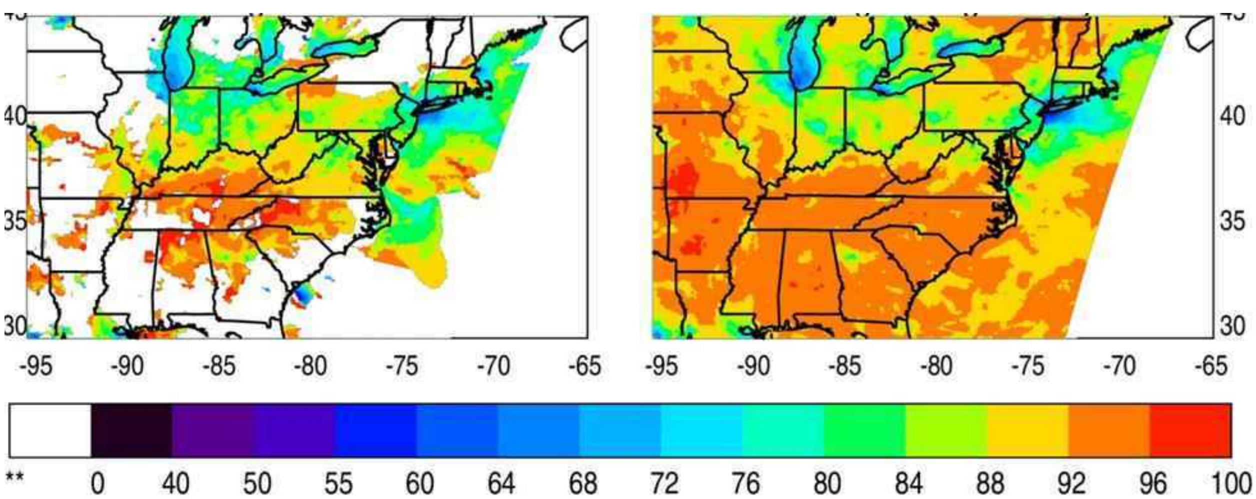

Figure 3. Percent of ozone formed under NOx-limited conditions excluding boundary and initial conditions on all days of MDA8 ozone > 60 ppb (left) and on top ten modeled days (right).

It is also noted that these estimates are a very conservatively high estimate of NOx limited conditions for these coastal areas. In addition to the previous comments highlighting that APCA is known to have a bias toward attributing ozone to NOx emitting anthropogenic sources under VOC sensitive conditions, the UMD analysis footnotes that the APCA run used to generate the results presented in Figure 3 suggests that model configuration led to an underestimation of the contribution of anthropogenic sources to ozone formation, especially during periods of VOC limited chemistry, and as is seen in Figure 3, in the Cook County, Illinois area.

As a result of these findings, EPA is obligated to address the concern that VOC emissions are a factor that is influencing ozone nonattainment and maintenance monitors in Illinois and elsewhere and that EPA determination of ozone nonattainment or maintenance in these areas may be inappropriate for significant contribution and upwind state linkage calculation. It is also our opinion that after review of VOC contribution and limited ozone reduction potential in Chicago and other noted areas, EPA may find that emission reduction plans may fail to justify regional NOx rules for monitors within these transitional and VOC-limited domains.

B. U.S. EPA's revisions to its modeling approach since MPCA's SIP submittal were ancillary.

EPA failed to give appropriate recognition of the merit of the MPCA SIP submitted on October 1, 2018, meeting the statutory deadline for submittal of interstate transport SIPs for the 2015 ozone NAAQS. The submission utilized both EPA modeling released with the March 2018 memorandum and LADCO modeling results previously mentioned. Minnesota followed the 4-step interstate transport framework and used an analytic year of 2023 to describe Minnesota's lack of contributions to out of state receptors and assess emission reduction considerations.

Under the CAA, on April 1, 2019, MPCA's SIP was deemed to be complete since EPA did not act within the 6 months from the date the SIP was submitted. April 1, 2020, 12 months after the completeness date, was the deadline for EPA to have acted on the MPCA SIP submission. Upon this deadline a full, partial or conditional approval was required by CAA Section 110(k)(2), (3), or (4).[24] In this regard, EPA failed to complete its non-discretionary duty to have reviewed and acted upon the MN SIP by April 1, 2020.

It wasn't until February 22, 2022, three years and four months after submittal, that EPA finally assessed the Minnesota SIP submittal and proposed disapproval of the SIP[25] as follows: "Based on EPA's evaluation of Minnesota's SIP submission and after consideration of updated EPA modeling using the 2016-based emissions modeling platform, EPA is proposing to find that the portion of Minnesota's October 1, 2018 SIP submission addressing CAA section 110(a)(2)(D)(i)(I) does not meet the state's interstate transport obligations for 2015 ozone NAAQS, because it fails to contain the necessary provisions to eliminate emissions that will contribute significantly to nonattainment or interfere with maintenance of the NAAQS in any other state."

The EPA reiterated this assessment and issued a partial approval on February 13, 2023, in their final rule stating that "Although the EPA acknowledges that Minnesota's Step 3 analysis was insufficient in part because the State assumed it was not linked at Step 2, this is ultimately inadequate to support a conclusion that the State's sources do not interfere with maintenance of the 2015 ozone NAAQS in other states in light of more recent air quality analysis."[26]

[24] **Deadline for Action**. – Pursuant to the CAA Section 110(k)(1)(B) "Within 12 months of a determination by the Administrator (or a determination deemed by operation of law) under paragraph (1) that a State has submitted a plan or plan revision (or, in the Administrator's discretion, part thereof) that meets the minimum criteria established pursuant to paragraph (1), if applicable (or, if those criteria are not applicable, within 12 months of submission of the plan or revision), the Administrator shall act on the submission in accordance with paragraph (3)."

[25] 87 Fed. Reg. 9838

[26] 88 Fed. Reg. 9357

1. EPA's Failure to Act

MPCA has been disadvantaged by EPA's delay in acting to approve or disapprove its 2015 Good Neighbor SIP, which was submitted to EPA on October 1, 2018. EPA published its proposed disapproval on February 22, 2022, and relied in part on newer, updated modeling performed by the EPA which was not available when MPCA submitted its revised SIP. On February 13, 2023, EPA published its final disapproval and again relied on even newer, updated modeling only released with the rule.

By delaying its final decision on Minnesota's submittal for nearly four and a half years, EPA moved the goal post for Minnesota—an act the DC Circuit rebuked in New York v. EPA, 964 F.3d 1214, 1223 (D.C. Cir. 2020). If EPA were to review and approve or disapprove SIPs within the timeframes required by the CAA, EPA would have conducted its review based on the same modeling and data that was available at the time the SIP was submitted and that has been documented in the sections above. EPA offers no indication that additional material information was available to EPA on April 1, 2020, when agency action on the Minnesota SIP was required that could justify disapproval of the Minnesota SIP.

Further, the updated modeling that EPA now offers to support a SIP review has not been adequately available to be reviewed, analyzed, and commented on in advance of any final decision on the subject SIP disapproval.

2. EPA has not developed any official guidance for states to follow in submitting a Good Neighbor SIP

The Good Neighbor SIP has been a required SIP element since the implementation of the 1997 8- hour ozone standard. In the intervening years, EPA has issued no official guidance for states to use in developing an approvable Good Neighbor SIP. It is unclear what standard or criteria EPA uses to determine approvability.

In its only direction on the subject, EPA released three 2018 memos that included modeling and discussion on potential flexibilities in approaches that could be used by states in developing their Good Neighbor SIPs. However, EPA has now disapproved MPCA's SIP which was based on EPA's own modeling results from the memo because it "does not meet the state's interstate transport obligations for 2015 ozone NAAQS, because it fails to contain the necessary provisions to eliminate emissions that will contribute significantly to nonattainment or interfere with maintenance of the NAAQS in any other state."[27]

[27] 87 FR 9869

From the memos, the only concrete guidance states have been provided is the four-step framework. Applied appropriately in the MPCA SIP, this framework demonstrated that Minnesota was not significantly linked to any downwind nonattainment or maintenance monitor. Since MPCA used EPA's own modeling and four-step approach to prepare its SIP, the SIP was approvable at the time submitted and was approvable when EPA was required to act on the SIP on April 1, 2020.

3. EPA's ever-changing list of nonattainment and maintenance monitors moves the target for Minnesota without offering any basis to reject MPCA's original analysis.

As detailed earlier, MPCA's air quality projections based on the ozone modeling conducted by LADCO in October 2018 was corroborated by EPA's own contribution modeling released with the March 2018 flexibilities memorandum and that showed that Minnesota was not linked to any monitor designated as nonattainment or maintenance for the 2015 ozone NAAQS in 2023. In those two modeling studies, the Cook County, Illinois monitor now linked to Minnesota was calculated to be in attainment for the 2015 ozone NAAQS.

Table 6 provides the average and maximum projected design values from the LADCO modeling that supported the original MPCA iSIP and March 2018 EPA memo modeling for this monitor demonstrating modeled attainment at this location.

			LADCO Modeling		EPA March 2018 Memo	
AQS Site ID	**State**	**County**	**2023 Average DV**	**2023 Maximum DV**	**2023 Average DV**	**2023 Maximum DV**
170310001	Illinois	Cook	62.8	64.6	63.2	64.9

Table 6. LADCO and EPA 2023 ozone design values (ppb) for Minnesota linked Cook County, Illinois monitor from original MPCA SIP and March 2018 EPA memo modeling results.

EPA's proposed disapproval mentions new modeling conducted by EPA in the interim where this Illinois monitor is ultimately identified as a maintenance monitor. Table 7 below provides the average and maximum projected design values from these studies and from the final SIP disapproval for this monitor.

In the proposed SIP disapproval, EPA cites the "results of a prior round of 2023 modeling using the 2016v1 emissions platform which became available to the public in the fall of 2020 in the Revised CSAPR Update." [28] In this Revised CSAPR Update modeling, developed for use with the 2008 ozone NAAQS analyses, monitor 170310001 is identified as a maintenance monitor in

[28] Footnote 94, 87 FR 9869

EPA's results. In EPA's results published in the proposed SIP disapproval[29] and in the final SIP disapproval[30], EPA continued to identify this monitor as a maintenance monitor.

AQS Site ID	EPA Revised CSAPR Update		EPA Proposed SIP Disapproval		EPA Final SIP Disapproval	
	2023 Ave DV	2023 Max DV	2023 Ave DV	2023 Max DV	2023 Ave DV	2023 Max DV
170310001	68.4	72.2	69.6	73.4	68.2	71.9

Table 7. EPA 2023 ozone design values (ppb) for Cook County, Illinois monitor from EPA cited modeling results in proposed and final Minnesota SIP disapproval.

In our opinion, EPA should always rely on the best available modeling at the time that an analysis is conducted and results, whether in a SIP or other, are developed and submitted. In this case, EPA has failed to follow this process and instead continued to move the target and objectives for states that, in Minnesota's case, for over four years and four months had been waiting for a review of their "best available data and analysis".

4. Alternative 1 ppb significance threshold

Neither the LADCO modeling nor EPA modeling released with the March 2018 memorandum indicated that Minnesota would contribute over 1% of the NAAQS to any nonattainment or maintenance monitor in 2023. As a result, Minnesota did not think it necessary to consider using a 1 ppb threshold for significant contribution to downwind receptors, which EPA guidance offered as an option to States.

In the SIP disapproval, EPA further elaborates that following their receipt and review of forty-nine good neighbor SIPs for the 2015 ozone NAAQS, their experience was that no state relying on a 1 ppb threshold provided sufficient information and technical support to justify that an alternative threshold was reasonable[31]. EPA does not indicate how many of the reviewed SIPs used a 1 ppb threshold nor do they indicate on how many state SIPs they provided feedback, if any. They go on to state that this alternate 1 ppb threshold may also be politically inconsistent and impractical under the CAA[32].

As EPA not only failed to provide any feedback to Minnesota on its original October 1, 2018 SIP submittal until the February 22, 2022 proposed SIP disapproval, EPA has also failed to honor its March 2018 guidance[33] which was identified to specifically "*provide analytical information*

[29] Table 5, 87 FR 9868
[30] Table III.B-2, 88 FR 9351
[31] 87 FR 9843
[32] Footnote 33, 87 FR 9843
[33] https://www.epa.gov/sites/default/files/2018-03/documents/transport_memo_03_27_18_1.pdf

regarding the degree to which certain air quality threshold amounts capture the collective amount of upwind contribution from upwind states to downwind receptors or the 2015 ozone NAAQS. It also interprets that information to make recommendation about what thresholds may be appropriate for use in state implementation plan (SIP) revisions addressing the good neighbor provision for that NAAQS."

Minnesota has been denied the opportunity to correct the model inputs that EPA uses as the basis for SIP Disapproval at the 1% threshold and denied the opportunity to update its SIP to take advantage of the 1 ppb threshold that EPA offers States an opportunity to justify in its guidance. While EPA continues to regenerate results based on updated emission modeling platforms and other associated information, states have been omitted from the process, denying them the chance to review updated information and to provide revisions to their SIPs to address those updates.

It is important to note that under all of EPA's cited modeling results, Minnesota contributes under the 1 ppb permitted to be considered from EPA's March 2018 guidance. Table 8 below shows that under none of EPA's four modeling platforms does Minnesota contribute over the 1 ppb threshold to the Cook County monitor.

			Minnesota Contribution (ppb) in 2023			
AQS Site ID	**State**	**County**	**EPA March 2018 Memo**	**EPA Revised CSAPR Update**	**EPA Proposed SIP Disapproval**	**EPA Final SIP Disapproval**
170310001	Illinois	Cook	0.76	0.79	0.97	0.85

Table 8. Minnesota contribution to Cook County, Illinois 2023 ozone design values from documented modeling platforms.

EPA's 2018 flexibility memos, including the opportunity for states to make recommendations to support alternate thresholds for significant contribution, remains an important tool for addressing unique State circumstances in developing their good neighbor SIPs. Disapproving the Minnesota SIP without affording the State an opportunity to utilize this flexibility is unreasonable and should be reconsidered.

C. The Minnesota Pollution Control Agency's state implementation plan revision was approvable based on the state of the science at the time it was submitted to U.S. EPA.

1. Introduction

On October 1, 2018, the Minnesota Pollution Control Agency, after review and comment by EPA Region 5 staff, submitted to the U.S. Environmental Protection Agency a request for revision of Minnesota's State Implementation Plan[34].

The proposed SIP revision addressed Minnesota's responsibilities relating to the "Infrastructure" SIP (iSIP) requirements of sections 110(a)(l) and 110(a)(2) of the Clean Air Act (CAA), as they pertain to the National Ambient Air Quality Standard (NAAQS) for ozone, promulgated in 2015. The CAA requires states to submit an iSIP within three years of the EPA's issuance of a new NAAQS to demonstrate their continued ability to implement, maintain, and enforce the federal standards. The iSIP outlined the statutes, rules, and programs that enable Minnesota to ensure attainment of the 2015 ozone NAAQS. These statutes, rules, and programs had previously been reviewed and approved into Minnesota's iSIP, and the materials included with the iSIP demonstrate that the MPCA did not have further obligations under the iSIP requirements.

The MPCA submission utilized both EPA modeling released with a March 2018 flexibilities memorandum[35] and Lake Michigan Air Directors Consortium (LADCO) modeling results[36]. Minnesota followed the 4-step interstate transport framework and used an analytic year of 2023 to describe Minnesota's lack of contributions to out of state receptors and assess emission reduction considerations.

In this document we discuss both the technical and legal validity of MPCA's SIP and EPA's obligation to approve the SIP.

EPA's and LADCO's model projections, along with continuing decreases in the emissions and monitored levels of ozone precursors in Minnesota (nitrogen dioxide and volatile organic compounds), demonstrated that no additional controls or emissions limits were necessary to

[36] https://www.ladco.org/wp-content/uploads/Documents/Reports/TSDs/O3/LADCO_2015O3iSIP_TSD_13Aug2018.pdf

fulfill Minnesota's responsibilities under the good neighbor provisions for the 2015 ozone NAAQS.

On February 13, 2023, almost four and a half years after the original SIP submittal, EPA finalized a rule in connection with the Air Plan Disapprovals; Interstate Transport Requirements for the 2015 8-Hour Ozone National Ambient Air Quality Standards[37].

EPA notes in this final rule, that these disapprovals would not start a mandatory sanctions clock but rather would establish a 2-year deadline for EPA to promulgate a Federal Implementation Plan (FIP), unless EPA were to approve a subsequent SIP submittal that meets CAA requirements. EPA originally proposed a FIP to be finalized December 15, 2022, in complete disregard for the 2-year period allowed by the CAA for responding to any such SIP disapprovals[38]. This FIP[39] was signed by the Administrator on March 15, 2023, and is still awaiting publication in the Federal Register.

In 2018 EPA issued flexibility guidance for states to follow in development of 2015 ozone standard NAAQS God Neighbor SIPs (GNS). We specifically question how EPA's late disapproval contradicts this guidance.

2. MPCA's Modeling Approach

The modeling performed to support the SIP was performed by LADCO and except for the 2023 projected EGU emissions, was identical to the "EN" platform developed by EPA and followed EPA guidance[40] in preparation of technical material for SIP and SIP-related modeling. The EN platform was used by EPA in its March 2018 flexibility memorandum so that "[s]tates can use these data to develop their implementation plans to assure that emissions within their jurisdictions do not contribute significantly to nonattainment or interfere with maintenance of the 2015 ozone standards in other states."

In our opinion, this platform was technically credible, and a SIP developed from these data should have been approvable by EPA at the time of submission in October 2018. The following sections present our opinions on specific technical aspects of MPCA modeling.

[37] Id.
[38] 87 Fed. Reg 20036
[39] https://www.epa.gov/system/files/documents/2023-03/FRL%208670-02-OAR_Good%20Neighbor_Final_20230314_Signature_ADMIN%20%281%29.pdf
[40] https://www.epa.gov/sites/production/files/2020-10/documents/o3-pm-rh-modeling_guidance-2018.pdf

Base Year

The base year for the MPCA modeling was 2011. 2011 was selected because of data availability and because EPA[41] had noted that 2011 meteorology in the Eastern U.S., including the upper Midwest, was warmer and drier that the climatic norm and represented typical conditions conducive to high observed ozone concentrations in the Midwest and Northeast U.S. It is Alpine's opinion that 2011 was an appropriate modeling year.

Model and Data Selection

This section introduces the models and data sources used in the MPCA. The selection methodology followed EPA's guidance for ozone regulatory modeling[42],[43],[44]. EPA's 2018 modeling guidance[45] lists several criteria for model selection that are paraphrased as follows (pp. 24-27):

- It should not be proprietary;
- It should have received a scientific peer review;
- It should be demonstrated to be applicable to the problem on a theoretical basis;
- It should be used with data bases which are available and adequate to support its application;
- It should be shown to have performed well in past modeling applications;
- It should be applied consistently with an established protocol on methods and procedures;
- It should have a user's guide and technical description;
- The availability of advanced features (e.g., probing tools or science algorithms) is desirable; and

- When other criteria are satisfied, resource considerations may be important and are a legitimate concern.

It is Alpine's opinion that the models chosen for the MPCA modeling met these criteria and were appropriate for use in the SIP.

Meteorological Modeling

The Weather Research and Forecasting (WRF) Model is a mesoscale numerical weather prediction system designed to serve both operational forecasting and atmospheric research needs[46],[47],[48]. The Advanced Research WRF (ARW) version of WRF was used in the MPCA modeling study. It features multiple dynamical cores, a 3-dimensional variational (3DVAR) data assimilation system, and a software architecture allowing for computational parallelism and system extensibility. WRF is suitable for a broad spectrum of applications across scales ranging from meters to thousands of kilometers. The effort to develop WRF has been a collaborative partnership, principally among the National Center for Atmospheric Research (NCAR), the National Oceanic and Atmospheric Administration (NOAA), the National Centers for Environmental Prediction (NCEP) and the Forecast Systems Laboratory (FSL), the Air Force Weather Agency (AFWA), the Naval Research Laboratory, the University of Oklahoma, and the Federal Aviation Administration (FAA). WRF allows researchers the ability to conduct simulations reflecting either real data or idealized configurations. WRF provides operational forecasting a model that is flexible and efficient computationally, while offering the advances in physics, numerics, and data assimilation contributed by the research community.

WRF is publicly available, has full documentation and has demonstrated success in simulating meteorological conditions in the Upper Midwest.

MPCA used the U.S. EPA 2011 WRF data for this study[49]. The U.S. EPA used version 3.4 of the WRF model, initialized with the 12-km North American Model (NAM) from the National Climatic Data Center (NCDC) to simulate 2011 meteorology. Complete details of the WRF simulation, including the input data, physics options, and four-dimensional data assimilation (FDDA) configuration are detailed in the U.S. EPA 2008 Transport Modeling technical support document[50]. U.S. EPA prepared the WRF data for input to CAMx with version 4.3 of the WRFCAMx software.

It is Alpine's opinion that the U.S. EPA WRF 3.4 meteorological modeling was appropriate for use in the MPCA SIP.

Initial and Boundary Conditions

MPCA used 2011 initial and boundary conditions for CAMx generated by the U.S. EPA from the GEOS-Chem Global Chemical Transport Model[51]. EPA generated hourly, one-way nested boundary conditions (i.e., global-scale to regional-scale) from a 2011 2.0 degree x 2.5 degree GEOS-Chem simulation. Following the convention of the U.S. EPA O3 transport modeling, year 2011 GEOS-Chem boundary conditions were used by LADCO for modeling 2023 air quality with CAMx.

It is Alpine's opinion that the U.S. EPA GEOS-Chem derived initial and boundary conditions were appropriate for use in the MPCA SIP.

Emissions

The 2023 emissions data for the MPCA SIP were based on the U.S. EPA 2011v6.3 ("EN") emissions modeling platform[52]. U.S. EPA generated this platform for their final assessment of Interstate Transport for the 2008 O3 NAAQS. Updates from earlier 2011-based emissions modeling platforms included a new engineering approach for forecasting emissions from Electricity Generating Units (EGUs). LADCO replaced the EGU emissions in the U.S. EPA EN

[52] US EPA. 2017. Technical Support Document: Additional Updates to Emissions Inventories for the Version 6.3 Emissions Modeling Platform for the Year 2023. Research Triangle Park, NC. https://www.epa.gov/sites/production/files/2017-11/documents/2011v6.3_2023en_update_emismod_tsd_oct2017.pdf

platform with 2023 EGU forecasts estimated with the ERTAC EGU Tool version 2.7[53]. ERTAC EGU 2.7 integrates state-reported information on EGU operations and forecasts as of May 2017. The MPCA believes “power sector emissions forecasts must address economic factors, preserve system reliability, and include controls or emission reduction measures justified through some legal framework. It is our understanding that the engineering analysis used by EPA to project EGU emissions to 2023 (version EN of the modeling platform) does not comply with these key requirements. The ERTAC estimates incorporate the key requirements.”[54]

In March 2018 U.S. EPA released it flexibilities memo that described a series of flexibilities that states could consider in developing Good Neighbor SIPs for the 2015 ozone NAAQS. The “[u]se of alternative power sector modeling consistent with EPA’s emissions inventory guidance” is presented in the Analytics section of EPA’s March 2018 memo as a flexibility to consider in preparing a Good Neighbor SIP. This flexibility supports LADCO’s use of the ERTAC EGU model for projecting EGU emissions to 2023. MPCA considers the emissions projections from ERTAC EGU to be more representative of the sources in the Midwest and Northeast than the approach used by U.S. EPA in their 2023 EN modeling platform. As ERTAC EGU is developed in collaboration between regional and state air planning agencies, it includes algorithms and data that have been reviewed by many of the states impacted by interstate O3 transport in the Midwest and Eastern U.S.

Preparation of the emissions data to support photochemical models is a very complicated process that entails the use of a number of different “sub-models” to prepare different emission segments.

Sparse Matrix Operator Kernel Emissions (SMOKE)

The Sparse Matrix Operator Kernel Emissions (SMOKE) is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, non-road, area, point, fire and biogenic emission sources for PGMs[55],[56]. As with most “emissions models,” SMOKE is principally an emission processing system and not a true emissions modeling system in which emissions estimates are simulated from “first principles.” This means that, except for mobile and biogenic sources, its purpose is to provide an efficient, modern tool for converting an existing base emissions inventory data that is typically at the county or point source level into

[53] http://www.marama.org/2013-ertac-egu-forecasting-tool-documentation

[54] EPA-R05-OAR-2018-0689-0003

[55] Coats, C.J. 1995. Sparse Matrix Operator Kernel Emissions (SMOKE) Modeling System, MCNC Environmental Programs, Research Triangle Park, NC.

[56] UNC. 2018. SMOKE v4.6 User’s Manuel. University of North Carolina at Chapel Hill, Institute for the Environment. Chapel Hill, North Carolina. September 24. (https://www.cmascenter.org/smoke/documentation/4.6/manual_smokev46.pdf).

the hourly gridded speciated formatted emission files required by a Photochemical Grid Model (PGM), like CAMx. SMOKE was used to prepare emission inputs for non-road mobile, non-point (area) and point sources. SMOKE performs three main function to convert emissions to the hourly gridded emission inputs for a PGM: (1) spatial allocation, spatial allocates county-level emissions to the PGM model grid cells typically using a surrogate distribution (e.g., population); (2) temporal allocation, allocates annual emissions to time of year (e.g., monthly or seasonally) and day-of-week (typically weekday, Saturday and Sunday); and (3) chemical speciation, maps the emissions to the species in the chemical mechanism used by the photochemical grid model, most important for VOC and $PM_{2.5}$ emissions.

The primary emissions modeling tool used to create the air quality model-ready emissions was the SMOKE modeling system version 3.7 which was used to create emissions files for a 12-km national grid "12US2" that includes all of the contiguous states.

It is Alpine's opinion that the SMOKE emissions model together with the other EPA emissions was appropriate for use in the MPCA SIP.

Motor Vehicle Emissions Simulator (MOVES)

The motor vehicle emissions were prepared by U.S. EPA using the MOVES 2014a emissions model[57],[58],[59]. MOVES 2014a was the most up to date released motor vehicle emissions processor at the time of the MPCA SIP submission and it is Alpine's opinion that the U.S. EPA MOVES 2014a emissions were appropriate for use in the MPCA SIP.

Eastern Regional Technical Advisory Committee EGU Model

The Eastern Regional Technical Advisory Committee (ERTAC) EGU model for growth was developed around activity pattern matching algorithms designed to provide hourly EGU emissions data for air quality planning. The original goal of the model was to create low-cost software that air quality planning agencies could use for developing EGU emissions projections. States needed a transparent model that was numerically stable and did not produce dramatic changes to the emissions forecasts with small changes in inputs. A key feature of the model

[59] EPA. 2014b. Motor Vehicle Emissions Simulator (MOVES) –MOVES2014 User Interface Manual. Assessment and Standards Division, Office of Transportation and Air Quality, U.S. Environmental Protection Agency. (EPA-420-B-14-067). July. (http://www.epa.gov/oms/models/moves/documents/420b14057.pdf).

includes data transparency; all of the inputs to the model are publicly available. The code is also operationally transparent and includes extensive documentation, open-source code, and a diverse user community to support new users of the software.

Operation of the model is straightforward given the complexity of the projection calculations and inputs. The model imports base year Continuous Emissions Monitoring (CEM) data from U.S. EPA and sorts the data from the peak to the lowest generation hour. It applies hour specific growth rates that include peak and off-peak rates. The model then balances the system for all units and hours that exceed physical or regulatory limits. ERTAC EGU applies future year controls to the emissions estimates and tests for reserve capacity, generates quality assurance reports, and converts the outputs to SMOKE ready modeling files.

ERTAC EGU has distinct advantages over other growth methodologies because it can generate hourly future year estimates which are key to understanding ozone episodes. The model does not shutdown or mothball existing units because economics algorithms suggest they are not economically viable. Additionally, alternate control scenarios are easy to simulate with the model. Full documentation for the ERTAC Emissions model and 2.7 simulations are available through the MARAMA website[60].

Differences between the EPA and ERTAC EGU emissions forecasts arise from alternative forecast algorithms and from the data used to inform the model predictions. The U.S. EPA EGU forecast used in the 2023 EN modeling used CEM data available through the end of 2016 and comments from states and stakeholders received through April 17, 2017[61]. ERTAC EGU 2.7 used CEM data from 2011 and state-reported changes to EGUs through May 2017. The ERTAC EGU 2.7 emissions used for the modeling represented the best available information on EGU forecasts for the Midwest and Eastern U.S. available during Spring-early Summer 2018.

The “consideration of state-specific information in identifying sources [e.g., electric generating units (EGUs) and non-EGUs] and controls” is one of the potential approaches in EPA’s March 2018 flexibilities memorandum. The use of the ERTAC EGU tool falls squarely within the parameters of this documented flexibility and it is Alpine’s opinion that MPCA’s used of EGU emission projections from this model were appropriate in the MPCA SIP.

Memorandum: Supplemental Information on the Interstate Transport SIP Submissions for the 2008 Ozone NAAQS under Clean Air Act Section 110(a)(2)(D)(i)(I), Research Triangle Park, NC. https://www.epa.gov/sites/production/files/2017-10/documents/final_2008_o3_naaqs_transport_memo_10-27-17b.pdf.

BEIS

Biogenic emissions were computed by U. S. EPA based on the same version of the 2011 meteorology data used for the air quality modeling and were developed using the Biogenic Emission Inventory System version 3.61 (BEIS3.61) within SMOKE. The landuse input into BEIS3.61 is the BELD version 4.1 which is based on an updated version of the USDA-USFS Forest Inventory and Analysis (FIA) vegetation speciation-based data from 2001 to 2014 from the FIA version 5.1.

It is Alpine's opinion that the U.S. EPA application of the BEIS model was appropriate for use in the MPCA SIP.

3. Air Quality Modeling

The MPCA modeling used the Comprehensive Air-quality Model with Extensions (CAMx) air quality model[62]. CAMx is a state-of-science "One-Atmosphere" multi-scale photochemical grid model (PGM) capable of addressing ozone, particulate matter (PM), visibility and acid deposition at regional, urban and local scale typically for periods of a year. CAMx is a publicly available open-source computer modeling system for the integrated assessment of gaseous and particulate air pollution. Built on today's understanding that air quality issues are complex, interrelated, and reach beyond the urban scale, CAMx is designed to (a) simulate air quality over many geographic scales, (b) treat a wide variety of inert and chemically active pollutants including ozone, inorganic and organic $PM_{2.5}$ and PM_{10} and mercury and toxics, (c) provide source-receptor, sensitivity, and process analyses and (d) be computationally efficient and easy to use.

The U.S. EPA has approved the use of CAMx for numerous ozone and PM State Implementation Plans throughout the U.S. and has used this model to evaluate regional mitigation strategies including those for most recent national transport rules, such as the Cross-State Air Pollution Rule (CSAPR), CSAPR Update, and the modeling used in justification of denial of the MPCA SIP. The MPCA used Version 6.4, which was released in December 2016. Unlike some of EPA's previous ozone modeling guidance that specified a particular ozone model (e.g., EPA 1991 Guidance[63]) or that specified the Urban Airshed Model (UAM)[64], the EPA now recommends that

[62] User's Guide: Comprehensive Air Quality Model with Extensions version 6.40. Novato, CA. http://www.camx.com/files/camxusersguide_v6-40.pdf

[63] Draft Guidance on the Use of Models and Other Analyses in Attainment Demonstrations for the 8-hr Ozone NAAQS". U.S. Environmental Protection Agency, Office of Air Quality Planning and Standards, Research Triangle Park, N.C. May.

[64] User's Guide for the Urban Airshed Model. Volume I: User's Manual for UAM (CB-IV) prepared for the U.S. Environmental Protection Agency (EPA-450/4-90-007a). Systems Applications International, San Rafael, CA.

models be selected for ozone SIP studies on a "case-by-case" basis. The latest EPA ozone guidance[65] (pp. 24) explicitly mentions the CAMx PGMs as one of the most commonly used PGMs that would satisfy EPA's selection criteria but notes that this is not an exhaustive list and does not imply that it is "preferred" over other PGMs that could also be considered and used with appropriate justification.

The CAMx model is updated regularly to both update the science in the model and to address coding errors (bugs) in the code. CAMx 6.5 was released at the end of April 2018, approximately 6 months prior to submission the MPCA SIP submission. It is customary for regulatory modeling to "freeze" the model version during the modeling process to keep the modeling on schedule.

It is Alpine's opinion that the CAMx 6.4 air quality model along with the EPA EN platform with 2023 EGU's updated to include ERTAC was appropriate for use in the MPCA SIP.

4. Model Performance

MPCA relied on the model performance evaluation (MPE) conducted by the U.S. EPA on the modeling platform that we used for this study[66] to establish validity in the modeling platform. In addition to the MPE for the base year CAMx simulation, the U.S. EPA reported full MPE results for the 2011 WRF modeling[67] used in the CAMx simulations.

It is Alpine's opinion that the EPA WRF and CAMx performance evaluations showed adequate performance and that the modeling was appropriate for use in the MPCA SIP.

5. Source Apportionment

MPCA used the CAMx Anthropogenic Precursor Culpability Assessment (APCA) tool to calculate emissions tracers for identifying upwind sources of ozone at downwind monitoring sites. MPCA

[65] Modeling Guidance for Demonstrating Air Quality Goals for Ozone, PM2.5, an Regional Haze. used the APCA technique because it more appropriately associates ozone formation to anthropogenic sources than the CAMx Ozone Source Apportionment Technique (OSAT). If any anthropogenic emissions are involved in a reaction that leads to ozone formation, even if the reaction occurs with biogenic VOC or NOx, APCA tags the ozone as anthropogenic in origin.

The APCA source apportionment tool has a robust theoretical basis and a long application history and it is our opinion that the APCA tool is appropriate for identifying upwind sources of ozone at downwind monitoring sites.

6. Interstate Transport Provisions – Section 110(a)(2)(D)

This section of the CAA requires SIPs to have provisions prohibiting sources from emitting air pollutants in amounts that would contribute significantly to nonattainment or interfere with maintenance in any other state. These interstate transport requirements are often referred to as “good neighbor SIPs”. The analyses conducted both by LADCO and EPA to support the 2015 ozone good neighbor SIPs show Minnesota does not contribute significantly to air quality problems in any downwind nonattainment or maintenance area. Therefore, no additional controls or emissions limits were required to fulfill Minnesota’s good neighbor obligations.

On March 27, 2018, the EPA published a memo, entitled “Information on the Interstate Transport State Implementation Plan Submissions for the 2015 Ozone National Ambient Air Quality Standards under Clean Air Act Section 110(a)(2)(D)(i)(I)”. EPA’s Memo included new transport modeling data for the year 2023 (the Moderate Attainment deadline for the 2015 ozone NAAQS). These data are provided to assist states in completing the “good neighbor” SIPs for the 2015 ozone NAAQS, and to thereby address interstate transport obligations.

EPA identifies a four-step framework in the Memo, intended to guide states on how to go about developing good neighbor SIPs:

1. Identify downwind air quality problems;
2. Identify upwind states that contribute enough to those downwind air quality problems to warrant further review and analysis;
3. Identify the emissions reductions necessary (if any), considering cost and air quality factors, to prevent an identified upwind state from contributing significantly to those downwind air quality problems; and
4. Adopt permanent and enforceable measures needed to achieve those emissions reductions.

In Step 1, EPA identifies monitoring sites that are projected to have problems attaining and/or maintaining the NAAQS in the 2023 analytic year. Where EPA’s analysis shows that a site does

not fall under the definition of a nonattainment or maintenance receptor, that site is excluded from further analysis under EPA's 4-step interstate transport framework. For sites that are identified as a nonattainment or maintenance receptor in 2023, we proceed to the next step of our 4-step interstate transport framework by identifying the upwind state's contribution to those receptors.

In Step 2, EPA quantifies the contribution of each upwind state to each receptor in the 2023 analytic year. The contribution metric used in Step 2 is defined as the average impact from each state to each receptor on the days with the highest ozone concentrations at the receptor based on the 2023 modeling. If a state's contribution value does not equal or exceed the threshold of 1 percent of the NAAQS (i.e., 0.70 ppb for the 2015 ozone NAAQS), the upwind state is not ''linked'' to a downwind air quality problem, and EPA, therefore, concludes that the state does not significantly contribute to nonattainment or interfere with maintenance of the NAAQS in the downwind states.

Comparably, in MPCA's SIP submission, they include LADCO's modeling which additionally follows the same transport framework and is corroborated by EPA's modeling with the data released with the March 2018 memo.

Step 1 - 2023 Air Quality Projections

MPCA's reported air quality projections[68] submitted with their SIP were based on the ozone modeling conducted by LADCO. The result of this LADCO 2023 modeling, using methods utilized by EPA and shown in Table 9 below, forecasted that no downwind monitors in the Midwest or Northeast would be nonattainment for the 2015 O3 NAAQS.

[68] Data source Table 5, Attachment 1, EPA-R05-OAR-2018-0689-0003

Table 9. LADCO 2023 ozone design values at EPA identified nonattainment and maintenance monitors in the Midwest and Northeast.

EPA's own modeling[69], released with the March 2018 platform, shown in Table 10, and designed to be used by states in development of their ozone transport SIPs, indicated that in the Midwest or Northeast, two downwind monitors in Fairfield, Connecticut (monitors 90013007 and 90019003), a monitor in Suffolk, New York (36103002), and monitors in Milwaukee (550790085) and Sheboygan (551170006), Wisconsin would be in nonattainment for the 2015 ozone NAAQS.

Table 10. EPA 2023 ozone design values at nonattainment and maintenance monitors in the Midwest and Northeast.

[69] https://www.epa.gov/sites/default/files/2018-05/updated_2023_modeling_dvs_collective_contributions.xlsx

An additional six monitors in Connecticut (90010017 and 90099002), Maryland (240251001), Michigan (260050003 and 261630019), and New York (360810124) would be considered maintenance monitors in the projection.

In neither the LADCO nor EPA modeling cited in MPCA's SIP revision submission were the two Cook County, Illinois monitors (170314201 and 170310076) from EPA's SIP denial NPR, or the single monitor from EPA's final SIP disapproval action, identified as either nonattainment or maintenance monitors in the 2023 projections.

Step 2 - Significant Contribution to Downwind States

EPA has previously determined that a state contribution to downwind air quality problems below one percent of the applicable NAAQS is insignificant. This screening method was used in previous good neighbor SIP approvals, and other regulatory actions including (most notably) the Cross-State Air Pollution Rule (CSAPR), and the CSAPR update for the 2008 ozone NAAQS and 2012 NAAQS for particulate matter less than 2.5 micrometers in diameter (PM2.5). The one percent screening method was developed through several previous federal notice and comment rulemakings. One percent of the 2015 ozone NAAQS (70 ppb) is 0.70 ppb. Therefore, any state that contributes less than 0.70 ppb to a projected nonattainment or maintenance area in another state is not culpable for those air quality problems.

EPA and LADCO applied the Anthropogenic Precursor Culpability Analysis (APCA) technique in CAMx to identify upwind states culpable for downwind ozone air quality problems. The method accounts for anthropogenic nitrogen oxides (NO_x) and volatile organic carbon (VOC) emissions from all sources in each upwind state affecting projected 2023 ozone concentrations at each downwind air quality monitoring site designated a nonattainment or maintenance receptor. EPA and LADCO conducted the culpability analysis for the period May 1 through September 30, using the 2023 future emission estimates and 2011 meteorology.

Both LADCO and EPA analyses[70] conclude Minnesota is not culpable for ozone nonattainment, or interference with maintenance, in any downwind states. As shown in Table 11, prepared using data from MPCA's SIP[71], LADCO's analysis shows a maximum contribution of 0.45 ppb to the identified maintenance monitors, less than the 0.70 ppb identified as 1% of the NAAQS (70 ppb). EPA's analysis[72] (Table 12) indicates Minnesota contributes most to Milwaukee, Wisconsin monitor site 550790085. At a concentration of 0.40 ppb, this contribution is roughly equal to 0.57% of the 2015 ozone NAAQS.

Table 12. EPA 2023 O3 design values at nonattainment and maintenance monitors in the Midwest and Northeast and Minnesota's calculated contribution.

For the reasons set forth in this section, it is our opinion that the modeling conducted and cited by MPCA in the development of its 2015 ozone NAAQS transport SIP revision of October 2018 was technically adequate and appropriate for the purpose it was intended and followed all available EPA guidance on preparing technical modeling for SIP and SIP-related analyses.

Additionally, in our opinion, the MPCA SIP adequately demonstrates that Minnesota is not a significant contributor to any downwind monitor identified as in nonattainment or maintenance for the 2015 ozone NAAQS and is corroborated by EPA modeling which included state-of-science configuration and platform at the time the original SIP was submitted.

D. Summary of Conclusions

For the reasons set forth in this document, it is our opinion that the modeling conducted and cited by MPCA in the development of its 2015 ozone NAAQS transport SIP revision of October 1, 2018 was technically adequate and appropriate for the purpose it was intended and should have been approved by EPA at the time of submission. It is further our opinion that decisions made by EPA to compare MPCA's original submitted modeling to recently updated modeling, developed by EPA over four years and four months later than the original Oct 2018 submission, are inconsistent with EPA precedent.

It is our opinion that in the absence of inclusion of Minnesota's and other stakeholder's valid emission modeling platform revision submissions, as requested by EPA, and multiple reruns of the air quality in both the base year (2016) and projection year (2023) simulations, EPA cannot appropriately identify monitors as nonattainment or maintenance, and in turn, cannot calculate upwind state significant contribution metrics from these same data. Non-EGU emission controls and their associated NOx emission reductions as documented and submitted by MPCA, could be enough to change nonattainment designations and linked significance using an updated platform and needs to be considered before making any final decision on denial of MPCA's SIP.

It is our opinion that EPA's use of modeling with poor performance at critical monitors amounts to an unreliable result when used to establish nonattainment or maintenance monitors under Step 1 or linkages under Step 2 of the 4-step framework. Should more refined modeling be undertaken to review the ozone formation potential at monitors located in these land-water interfaces, results may show that these monitors demonstrate modeled attainment and/or remove significant contribution linkages from upwind states.

It is our opinion that the most recent modeling cited by EPA and used to justify the linkage of Minnesota to one downwind maintenance monitors in Cook County, Illinois has technical issues as it relates to that linked monitor which is located in a complex land-water interface and may require finer grid resolution modeling to adequately capture ozone formation and significant contribution, and that EPA must address the impact of VOC emissions in influencing ozone formation at monitors in Illinois.

It is our opinion that EPA has failed to follow the process by relying on the best available modeling at the time that an analysis is conducted, and results are developed and submitted. Instead, EPA continues to move the target and objectives for states that, in Minnesota's case, for over four years had been waiting for a review of their "best available data and analysis".

It is our opinion that EPA should not have used any updated modeling to support a SIP review while not providing the opportunity for that data to be reviewed, analyzed, and commented on in advance of any final decision on the subject SIP disapproval and that any modeling beyond what was conducted in the original SIP submittal was ancillary to the approval process. However, should EPA decide not to review MPCA's SIP revision on its merit, Alpine recommends that EPA withdraw the SIP disapproval in favor of correcting the technical errors that have been identified in its analysis and to propose an appropriate opportunity for Minnesota to address any deficiencies EPA may find in Good Neighbor Plans implementing the 2015 ozone NAAQS.

It is our opinion that EPA's 2018 flexibility memo has become so instrumental to states in developing their good neighbor SIPs, that EPA's decision to disallow the flexibilities that they themselves outlined in guidance, is unreasonable and should be reconsidered.

Additionally, in our opinion, the MPCA SIP adequately demonstrates that Minnesota is not a significant contributor to any downwind monitor identified as in nonattainment or maintenance for the 2015 ozone NAAQS and is corroborated by EPA modeling which included state-of-science configuration and platform at the time the original SIP was submitted. It is our opinion that the original MPCA SIP was and is approvable.

ALPINE GEOPHYSICS

E. Minnesota 2015 Ozone SIP Timeline

October 1, 2015 – EPA finalized the revised 2015 ozone NAAQS. Pursuant to CAA section 110(a)(1), "each state shall . . . submit to the Administrator, within 3 years. . .after promulgation of a [primary NAAQS] (or any revision thereof) a plan which provides for implementation, maintenance, and enforcement of such primary standard. . ." CAA section 110(a)(2)(D)(i)(I) requires such SIPs to "contain adequate provisions prohibiting . . .any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will contribute significantly to nonattainment in, or interfere with maintenance by, and other State with respect to such NAAQS.

March 27, 2018 - EPA published a memo, entitled "Information on the Interstate Transport State Implementation Plan Submissions for the 2015 Ozone National Ambient Air Quality Standards under Clean Air Act Section 110(a)(2)(D)(i)(I)". EPA's Memo included new transport modeling data for the year 2023 (the Moderate Attainment deadline for the 2015 ozone NAAQS). These data are provided to assist states in completing the "good neighbor" SIPs for the 2015 ozone NAAQS, and to thereby address interstate transport obligations.

October 1, 2018 - Minnesota Pollution Control Agency (MPCA) submitted a SIP revision to address CAA Section 110(a)(2)(D)(i)(I) on October 1, 2018 .[73] The submission met the statutory deadline for submittal the interest transport SIPs for the 2015 ozone NAAQS. The submission utilized both EPA modeling released with the March 2018 memorandum and LADCO modeling results previously mentioned. Minnesota followed the 4-step interstate transport framework and used an analytic year of 2023 to describe Minnesota's lack of contributions to out of state receptors and assess emission reduction considerations.

April 1, 2019 – This is 6 months after EPA received the Minnesota SIP submission and is the date that the CAA deems the Minnesota submittal to have been complete since EPA did not take action otherwise.

September 13, 2019 - The D.C. Circuit issued a decision in *Wisconsin v. EPA*, remanding the CSAPR Update to the extent that it failed to require upwind states to eliminate their significant

[73] **Completeness Finding** - Pursuant to the CAA Section 110(k)(1)(B) "Within 60 days of the Administrator's receipt of a plan or plan revision, but no later than 6 months after the date, if any, by which a State is required to submit the plan or revision, the Administrator shall determine whether the minimum criteria established pursuant to subparagraph (A) have been met. Any plan or plan revision that a State submits to the Administrator, and that has not been determined by the Administrator (by the date 6 months after receipt of the submission) to have failed to meet the minimum criteria established pursuant to subparagraph (a), shall on that date be deemed by operation of law to meet such minimum criteria."

contribution by the next applicable attainment date by which downwind states must come into compliance with the NAAQS, as established under CAA section 181(a). 938 F.3d at 313.

April 1, 2020 – This is 12 months after the completeness date and is the deadline for EPA to have acted on the MN SIP submission. Upon this deadline a full, partial or conditional approval was required by CAA Section 110(k)(2), (3), or (4).[74]

May 19, 2020 - the D.C. Circuit issued a decision in *Maryland v. EPA* that cited the Wisconsin decision in holding that EPA must assess the impact of interstate transport on air quality at the next downwind attainment date, including Marginal area attainment dates, in evaluating the basis for EPA's denial of a petition under CAA section 126(b). Maryland v. EPA, 958 F.3d 1185, 1203-04 (D.C. Cir. 2020). The court noted that "section 126(b) incorporates the Good Neighbor Provision," and, therefore, "EPA must find a violation [of section 126] if an upwind source will significantly contribute to downwind nonattainment at the next downwind attainment deadline. Therefore, the agency must evaluate downwind air quality at that deadline, not at some later date." Id. at 1204 (emphasis added). EPA interprets the court's holding in Maryland as requiring the states and the Agency, under the good neighbor provision, to assess downwind air quality as expeditiously as practicable and no later than the next applicable attainment date, which is now the Moderate area attainment date under CAA section 181 for ozone nonattainment. The Moderate area attainment date for the 2015 ozone NAAQS is August 3, 2024. At the time of the statutory deadline to submit interstate transport SIPs (October 1, 2018), many states relied upon EPA modeling of the year 2023, and no state provided an alternative analysis using a 2021 analytic year (or the prior 2020 ozone season). However, EPA must act on SIP submittals using the information available at the time it takes such action. In this circumstance, EPA does not believe it would be appropriate to evaluate states' obligations under CAA section 110(a)(2)(D)(i)(I) as of an attainment date that is wholly in the past, because the Agency interprets the interstate transport provision as forward looking. See 86 FR at 23074; see also Wisconsin, 938 F.3d at 322. Consequently, in this proposal EPA will use the analytical year of 2023 to evaluate each state's CAA section 110(a)(2)(D)(i)(I) SIP submission with respect to the 2015 ozone NAAQS.

May 12, 2021 – Downwinders at Risk, et al filed Case No. 21 Civ. 21 Civ 3551 asserting that EPA failed to undertake certain non-discretionary duties under the CAA.

---

[74] **Deadline for Action**. – Pursuant to the CAA Section 110(k)(1)(B) "Within 12 months of a determination by the Administrator (or a determination deemed by operation of law) under paragraph (1) that a State has submitted a plan or plan revision (or, in the Administrator's discretion, part thereof) that meets the minimum criteria established pursuant to paragraph (1), if applicable (or, if those criteria are not applicable, within 12 months of submission of the plan or revision), the Administrator shall act on the submission in accordance with paragraph (3)."

February 22, 2022 - EPA assessed the Minnesota submittal and on February 22, 2022 (3 years, 4+ months after submittal) the agency proposed denial of the Minnesota SIP as follows: "Based on EPA's evaluation of Minnesota's SIP submission and after consideration of updated EPA modeling using the 2016-based emissions modeling platform, EPA is proposing to find that the portion of Minnesota's October 1, 2018 SIP submission addressing CAA section 110(a)(2)(D)(i)(I) does not meet the state's interstate transport obligations for 2015 ozone NAAQS, because it fails to contain the necessary provisions to eliminate emissions that will contribute significantly to nonattainment or interfere with maintenance of the NAAQS in any other state. Air Plan Disapproval; Illinois, Indiana, Michigan, Minnesota, Ohio, Wisconsin; Air Plan Disapproval; Region 5 Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 87 Fed. Reg. 9838 (Feb. 22, 2022).

February 28, 2022 – EPA and Downwinders et al established in a Consent Decree entered into on 1/12/2022 that if EPA proposed a full or partial denial of the Minnesota SIP EPA shall have until December 15, 2022 to sign a final action. Note this is a settlement and does not erase the fact that EPA failed to complete its non-discretionary duty to have reviewed and acted upon the MN SIP by April 1, 2020.

April 30, 2022 – EPA and Downwinders, et established in a Consent Decree entered into on 1/12/2022 that required EPA to sign for publication final rulemaking on April 30, 2022 to approve, disapprove, and conditionally approve the Minnesota SIP submissions for the 2015 ozone NAAQS.

May 22, 2022 – EPA proposed to approve most elements of the Minnesota October 1, 2018 submission intended to address all applicable infrastructure requirements for the 2015 NAAQS. (87 FR 31462).

July 29, 2022 – EPA approved most elements of the Minnesota October 1, 2018 SIP submission from Minnesota regarding infrastructure requirements for the 2015 ozone NAAQS. EPA did not act on the interstate transport requirements and visibility impairments requirements. (87 FR 45663).

December 8, 2022 – EPA and Downwinders et al filed a Joint Motion of Stipulated Extension of Consent Decree deadlines that provided the following schedule.

December 15, 2022 – Former agreed upon deadline by Downwinders for EPA to act on Minnesota SIP, but this deadline was moved by agreement to January 31, 2022.

January 31, 2023 - deadline to sign final action on Minnesota SIP pursuant to agreed upon extension of Downwinders Consent Decree.

February 13, 2023 – EPA publishes final disapproval of State Implementation Plan (SIP) submissions for 19 states, including Minnesota. Air Plan Disapprovals; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 88 FR 9336.

March 15, 2023 – EPA issues final federal Good Neighbor Plan for the 2015 ozone NAAQS (publication in the Federal Register is still pending).

Motion to Stay, *United States Steel Corporation v. EPA*, *et al.*, Case No. 23-1207 (D.C. Cir.)

Exhibit L

Declaration of Alexis Piscitelli in Support of United States Steel Corporation's Motion for Stay (Aug. 22, 2023)

IN THE UNITED STATES CIRCUIT COURT
FOR THE DISTRICT OF COLUMBIA CIRCUIT

UNITED STATES STEEL CORPORATION, Petitioner v. UNITED STATES EVIRONMENTAL PROTECTION AGENCY, and MICHAEL S. REGAN, Administrator, U.S. EPA, Respondents.	Case No. 23-1207 Consolidated with Case Nos. 23-1157 (lead), 23-1181, 23-1183, 23-1190, 23-1191, 23-1193, 23-1195, 23-1199, 23-1200, 23-1201, 23-1202, 23-1203, 23-1205, 23-1206, 23-1208, 23-1209, and 23-1211

Declaration of Alexis Piscitelli in Support of United States Steel Corporation's Motion for Stay

I, Alexis Piscitelli, am over 18 years of age and make the following declaration pursuant to 28 U.S.C. § 1746:

1. I am the Senior Director Environmental for North American Flat Roll. at United States Steel Corporation ("U. S. Steel"), where I am responsible for ensuring compliance and reporting requirements are met in accordance with federal, state and local environmental permits and regulations. I have been employed by U. S. Steel for over 26 years and have advanced through various positions.

2. I am providing this declaration on behalf of U. S. Steel's Motion for Stay of the United States Environmental Protection Agency's ("EPA's") Federal "Good Neighbor Plan" for the 2015 Ozone National Ambient Air Quality

Standards ("Good Neighbor Plan" or "Final Rule"), 88 Fed. Re. 36,654 (June 5, 2023).

3. As further explained in this declaration, the Final Rule will require immediate actions by U. S. Steel, including either curtailing the operation of reheat furnaces and boilers at U. S. Steel, or the expenditure of millions of dollars to prepare now for implementation of the Good Neighbor Plan. Either or both of these actions will impose significant additional cost on U. S. Steel. Curtailing or the potential shutdown of the reheat furnaces would impact downstream units and ultimately customers. Curtailing the boilers will reduce electricity generation and increase the demand for outside purchased power, increasing costs and putting additional strain on the grid.

4. The Good Neighbor Plan also omits important flexibilities U. S. Steel uses to effectively and efficiently manage its environmental obligations.

5. This declaration is based on my personal knowledge of facts and information pertaining to U. S. Steel's business and the implications of EPA's Good Neighbor Plan. My knowledge is based on my history with U. S. Steel and analysis U. S. Steel has conducted of the Good Neighbor Plan.

I. The Implementation Schedule for the Good Neighbor Plan is Insufficient

6. In response to the Good Neighbor Plan, U. S. Steel developed a schedule for compliance with the regulatory obligations applicable to U. S. Steel – Gary Works' 84" Hot Strip Mill.

7. Based on our experience with projects of similar size and complexity, the assessment, design, permitting, and installation of low-NOx burners at all four furnaces will not be complete until May 2027, over a year beyond the May 2026 deadline for certification of completion of installation of low-NOx technology in the Good Neighbor Plan. A copy of the project schedule is included as Appendix A to the attached Barr report (Attachment 1).

8. This schedule conservatively assumes that permitting can be completed in six months. Based on my experience, permitting can take significantly longer, leading to additional delays in completion.

9. U. S. Steel has also had difficulty obtaining vendor quotes for the required work. Consistent with U. S. Steel practice, our contractor, Barr, has attempted to obtain three separate vendor quotes for each technology U. S. Steel is analyzing. Only two firms provided full responses as of July 7, 2023. For one technology, selective non-catalytic reduction ("SNCR"), Barr contacted at least eight vendors but was able to obtain only two estimates. This further demonstrates the need for additional time for

implementation of the Good Neighbor Plan, as we anticipate vendors will continue to experience backlogs and supply chain disruptions.

10. U. S. Steel has also had difficulty finding and scheduling qualified union contractors to work on significant projects at our facilities. For example, there are four reheat furnaces at Gary, each will require a significant outage to retrofit the equipment with low NOx burners or the equivalent. We anticipate the availability of qualified union workers will become even a larger issue with multiple sources being impacted by the Good Neighbor Plan.

II. Implementation of the Good Neighbor Plan Requires U. S. Steel to Incur Immediate and Significant Costs

11. Among other things, the Good Neighbor Plan as promulgated imposes requirements on certain reheat furnaces at iron and steel mills, including the requirement to design a low-NOx burner or alternative low-NOx technology to achieve NOx emission reductions of at least 40% from baseline emission levels measured during performance testing that meets the criteria set forth in the rule. Additional obligations include emissions monitoring, recordkeeping, and reporting requirements.

12. While I agree that requiring a universal, hard limit for reheat furnaces is not appropriate, the requirement to design to meet a minimum 40% reduction of NOx from baseline is not appropriate because it does not take into account

what is achievable for each reheat furnace, including what the baseline value actually is – whether, for example, it is 0.12 lb/MMBtu or 0.24 lb/MMBtu, what limits there are on the type of NOx reduction technology that can be used, what fuels the reheat furnace uses, what other pollution control technologies are already in place, or other factors that may make a minimum 40% reduction on some units technically or economically infeasible.

13. Baseline emission level performance testing cannot be completed without significant modification. For example, the reheat furnaces at Gary are very difficult to access. Testing equipment required to meet the USEPA specification cannot be used as currently configured. The facility will require engineered modification to provide access for personnel and equipment to conduct the required testing to establish a baseline for at least a 40% reduction design.

14. Based on the deadlines in the Good Neighbor Plan, which include submitting a completed work plan by August 5, 2024, U. S. Steel has already needed to begin project engineering and design and is already incurring significant costs to complete this work. Without a stay, and while the rule is subject to petitions for review, these costs are expected to substantially

increase in the coming months with EPA's aggressive rule implementation schedule.

15. Based on an initial assessment of the costs supported by vendor quotes, I estimate installing low-NOx burners at the four reheat furnaces at U. S. Steel – Gary Works' 84" Hot Strip Mill will cost between approximately $28 million to more than $46 million. *See* Attachment 1 at Table 4-1. This does not include additional operating costs associated with the new equipment or additional monitoring, performance testing, recordkeeping, and reporting costs associated with the Good Neighbor Plan.

16. This results in an estimated cost effectiveness of between $18,300 and $42,300 per ton NOx removed. Attachment 1 at Table 4-2. This far exceeds $3,656/ton average EPA includes in its Technical Memorandum to support the Final Rule. Summary of Final Rule Applicability Criteria and Emissions Limits for Non-EGU Emissions Units, EPA-HQ-OAR-2021-0668-0956, at Table 6 (March 15, 2023). It also far exceeds EPA's marginal cost threshold of $7,500/ton, the average cost-per-ton range for all non-EGUs of $939/ton to $14,595/ton, and even the $11,000/ton representative EGU retrofit cost EPA used for comparison in the Good Neighbor Plan. Final Rule at 36,746.

17. Without the Good Neighbor Plan, U. S. Steel would not need to incur these costs.

18. To comply with the Good Neighbor Plan, U. S. Steel will need to take reheat furnaces and boilers offline while they are retrofitted. This will involve multiple outages that would be unnecessary without the Good Neighbor Plan. These outages will impact production capabilities and may lead to the flaring of by-product fuels, wasting a valuable resource.

19. A stay of the FIP is necessary to avoid these unnecessary costs and outages until a final decision is reached on what obligations should apply to reheat furnaces and boilers at iron and steel mills.

20. Without a stay, U. S. Steel will incur significant and irreparable harm in reconfiguring the hot strip mill at Gary Works to allow for baseline performance testing and implementing the rule's requirements at the Company.

III. **The Cumulative Burdens of the Good Neighbor Plan and Other Federal Requirements will Be Substantial and Could Have a Material Impact on Critical Infrastructure, National Security, and U. S. Steel Operations.**

21. The U.S. steel industry is responsible for over $520 billion in economic output, supporting over 2 million jobs. It generates over $56 billion in tax revenues annually.

22. In a study conducted under Section 232 of the Trade Expansion Act of 1962 (19 U.S.C. §1862), the U.S. Department of Commerce determined that domestic steel production is essential for national security; and that domestic

steel production depends on a healthy and competitive U.S. industry. (*See* https://www.bis.doc.gov/index.php/other-areas/office-of-technology-evaluation-ote/section-232-investigations).

23. The Cybersecurity & Infrastructure Security Agency has identified the iron and steel industry as a core critical infrastructure industry impacting transportation systems, electric power grid, water systems, and energy generation systems. (*See* https://www.cisa.gov/topics/critical-infrastructure-security-and-resilience/critical-infrastructure-sectors/critical-manufacturing-sector).

24. Implementation of the Final Rule upon the steel industry, when at the same time implementing new rules upon all facets of domestic steel manufacturing also potentially jeopardizes thousands of good-paying USW jobs.

25. U. S. Steel is committed to continuing to work with federal partners to develop and implement scientifically sound regulations that effectively and demonstrably benefit the environment.

26. EPA's promulgation of overlapping Clean Air Act regulations without adequate consideration of their interaction undermines these efforts.

27. At the same time that EPA promulgated the Good Neighbor Plan, where it is mandating the installation of controls at reheat furnaces and boilers at iron

and steel mills, EPA is proposing new MACT standards at taconite, integrated iron and steel facilities, and coke plants; as well as proposing revised NAAQS standards (e.g., PM2.5) which, combined, could have a material impact on the domestic steel industry, significantly affect the schedule for achieving these requirements, and result in a shortage of available technical support for implementation of these rules.

28. As noted above, U. S. Steel is already having difficulty obtaining qualified contractors and vendor quotes. These additional rules will exacerbate the problem.

29. EPA has also announced that it anticipates proposing reconsideration of the current ozone NAAQS in April 2024. As a result, EPA may be revising the ozone NAAQS at the same time that the Good Neighbor Plan is requiring U. S. Steel to install pollution controls to address the current standards. Piecemealing these two rules, for which implementation will likely overlap, is problematic and inappropriate, as U. S. Steel could quite possibly be compelled to install additional or different controls on the same emission units following EPA's reconsideration. This would result in significant waste and could be avoided if EPA withdraws the Good Neighbor Plan and takes the two years allowed by the Clean Air Act for implementation of a revised FIP.

IV. **Conclusion**

30. In my opinion, the schedule set forth in the Good Neighbor Plan is not realistic and underestimates the time needed for compliance by at least a year. If emission units cannot achieve compliance by the scheduled deadlines and the deadlines are not stayed or extended, those emission units will be required to curtail operation. As a result. U. S. Steel is already required to incur substantial costs in order to prepare for the upcoming Good Neighbor Plan deadlines despite pending petitions for reconsideration and judicial review that may affect the applicability of the Good Neighbor Plan and the obligations that it imposes on reheat furnaces and boilers.

31. A stay of the Good Neighbor Plan will mitigate these harms.

I declare, under penalty of perjury, that the foregoing is true and correct. Executed on August 22, 2023.

Alexis Piscitelli
Sr. Director Environmental – NAFR
United States Steel Corporation
